has been most successfully attacked in quite a different manner by Professor Hale, of the Kenwood Physical Observatory, at Chicago, and fourteen years ago some very successful photographs of the corona and prominences were obtained by him, and daily photographs were taken for some time. Professor Hale's method was to take advantage of the fact that by enormously increasing the dispersion by the aid of a diffraction grating, the continuous spectrum of the sun itself was very much reduced, whilst the bright line spectra of the prominences remained strong, and selecting the K line of calcium, the extension and form of the prominences were accurately mapped out. A further improvement in this arrangement was made by using two moveable slits, the second of which isolated the K line, whilst the image of the sun itself was prevented from falling on the plate by an opaque diaphragm in contact with the slit; a slow rate of motion was then given to the slits, the corona photographed and the diaphragm removed: and with a very rapid motion of the slits the body of the sun itself photographed. The whole operation only took one minute, and the operation was automatically repeated every five minutes. The movement of the various parts of the instrument was effected by means of a glycerine clepsydra.

The Action of Stannous Chloride on Silver Bromide.

In 1897 Professor Namias, of Milan, pointed out that stannous chloride, $\text{SnCl}_2 \cdot 2\text{H}_2\text{O}$, caused a much quicker precipitation of metallic silver from the ammonio-tartrate of silver solution, used for silvering mirrors, and, led by this fact, he has been experimenting with gelatino-bromide plates and papers, and finds that a 1 per cent. solution acts on the bromide exactly the same as light, producing a latent image, and that with excessive action general fog is caused in the same way. He also points out that those who hold with the chemical theory of the latent image may find in this another support for their views. The action of the chloride of tin must be infinitely little, for, assuming that a 12 by 9 cm. plate contains 0.1 gramme of silver bromide, and a latent image is produced by 0.00025 g. of stannous chloride, and this is assuming that the whole acts, which is not the case, the actual amount of bromide reduced to sub-bromide is only 0.0001 g., that is to say, only one thousandth part of the total weight of bromide. Namias does not believe in the sub-bromide theory, and asks, "As so little sub-bromide is formed, how is it that the action extends to the whole of the bromide?" The interesting point of his communication, which appears in the "Photographische Correspondenz," is that bromide plates and paper, soaked in a 3 per cent. solution of stannous chloride and dried, will print right out, and the image withstands the action of hypo.

The Art of Advertising.

A copy of "St. Louis Republic" of March 24 contains a short paragraph with a plain lesson for the photographer who is seeking to make his work and his studio like household words in the community from which he draws his customers. "At a meeting of business and professional men," runs the article, "last night in the 'Growlery' at Strauss's Studio, plans were completed to organise a society to promote the interest of art in St. Louis. A meeting is to be held next Tuesday night at the same place to draw up papers of incorporation and to appoint committees." The full meaning of these sentences may not be patent to everybody. Everybody perhaps does not know how Mr. Strauss, by the force of personality and astute knowledge of the men and women of St. Louis has made his establishment one of the institutions of that city. Not every photographer is a Strauss,

and not every photographer has Strauss's opportunities. To few men does it occur that a persistent policy can succeed in making a photographer's gallery the place to spend a spare half hour. Mere sumptuous premises do not do that. Mr. Strauss has a palace of art, but the magnetism which draws people implies something more than pouring out money like water. There was his exhibition of portraits of the well-known bachelors in St. Louis society; and that is only one of a series of steps taken with a profound knowledge of what will interest people and set them talking. That Mr. Strauss has pursued this course without sacrificing, but instead intensifying, the dignity of his business should encourage every photographer to examine his own circumstances. We do not suggest that a photographer's studio can or should become the obvious venue for public movements such as that quoted above from the St. Louis newspaper, but we do declare that many photographers disregard such opportunities for quiet, dignified, but nevertheless influential publicity.

PLATE SPEEDS.

IN the early days of the gelatine plate we were quite content to accept the definition of the speed of a plate as so many "times" wet plate, but this method was soon supplanted by the use of Warnerke's sensitometer, which, whilst an improvement, was by no means satisfactory, particularly if his phosphorescent tablet was used as the standard light, and it was customary to take the number of the last square that could be read after fixation and call the plate of this speed, though it might frequently happen that this, and probably three or four other numbers were so faint as to be absolutely useless for printing purposes. At the same time possibly one or two numbers were so over-exposed as to be useless, so that the range of the plate was curtailed. Then, again, the instruments differed so much that they could not be compared one with another.

When Messrs. Hurter and Driffeld described their system many of us hoped that we had once for all a real settlement of the question, and that uniformity would be evolved from the previous chaotic condition of plate-speed testing. Unfortunately, chiefly through a misconception of terms, this system was vigorously attacked, and it was some years before it became generally adopted by plate makers, and even now one cannot actually compare the numbers as found by different workers. That this should be so is a matter of regret, as we know that if rigorously carried out according to the lines laid down by the original investigators, this might be so.

It is well known that the whole of the original experiments were carried out with the standard candle, and exception was naturally taken to this on account of its spectrum composition, a like objection being raised against the standard pentane lamp. And we do not think that it necessarily follows that one plate is faster than another to daylight, though it may have been proved to be so by an artificial light. As a matter of fact, we can state that in a dull light one plate may prove to be faster than another, and the variation in the brightness of individual parts of the spectrum may also lead to variation in speed, even although the plates may have been tested by the calibrated acetylene light of Messrs. Sheppard and Mees.

Assuming, however, that we adopt acetylene as the standard light source, there is another and an important point which seems to be somewhat neglected, and that is the action of the various developing agents on the speed of

the plate. The original standard developer was ferrous oxalate, to which there was the very grave objection that it was rarely if ever used in negative work, and the speeds obtained by it were not the speeds obtained by an operator when using pyro-soda or any other developer, and therefore pyro-soda was later adopted; but while this may be practically the standard developer for the studio and professional work, we should imagine that the majority of amateurs use one of the newer developing agents, and then the H. and D. speed is not or may not be as stated.

In confirmation of this point, which is disputed, we may be permitted to quote Mr. Driffeld, who says in "The Photo-Miniature," November, 1903, page 361:—"As the activity of the various reagents employed as developers differ considerably, it is necessary to adopt a standard developer for the purpose of speed determination, if the results obtained by different operators are to be comparable. To the amateur, however, who employs our system simply for his own guidance, it is quite open, of course, to employ any developer he thinks fit, but he must clearly understand that the speeds he obtains will not necessarily correspond with those obtained with our standard."

As we write there lies before us an H. and D. chart of a plate which was exposed under standard conditions, then cut in two, the one strip being developed with the standard pyro-soda, and the other with metol and hydroquinone. With the former the speed is 113; with the latter, 170—a considerable difference, and one which, it may be said, is of no moment, because all plates have now a latitude which is much greater than this. In the "Photographic Journal" for April, 1900, Mr. Watkins's paper on "Some Developers Compared" appears, and he states there that using pyro, metol, ortol, kachin, hydroquinone and glycin, in equal strengths, equal alkali, and no bromide, his results could be summed up as follows:—Effect on speed of plate, very slight or doubtful difference; searching out detail, no difference; ultimate density power, no difference discovered; fogging propensity, no difference; effect on different gradations, no difference; appearance of image, wide difference; speed of working, wide difference. This, then, is directly opposed to Mr. Driffeld's statement, and to one made some years ago by Messrs. Hurter and Driffeld, in which they stated that they found some plates three times as fast with rodinal.

Again Mr. John Sterry says in his excellent little work "Photography by Rule," 1903, pp. 48 and 49:—

"It has been noticed in practice it is not necessary in most cases to carry development as far as possible, and that differences in the action of developers are very marked in consequence. One of the principal effects of this is shown in the different results obtained from the same exposures with different developers. This may also be stated thus: The effective speed of the plate varies with the developer used. To a less extent, the same developer may give a difference of speed according to the relative amounts of the developing agent and alkali that are used. Whilst all these differences may be brought into effect at will, it is evident that they will only lead to confusion if not thoroughly understood. It is only by careful scientific measurements that all the differences can be mastered, for even the same make of plates will not always behave in the same manner. In the case of a series tried together it was found that usually plates were about one and a half times as rapid with pyro as with ferrous oxalate, and three times as rapid with eikonogen and rodinal; but the latter gave more trouble in obtaining sufficient density. . . . In one case a plate was found to be ten times

as rapid with rodinal as pyro-ammonia when specially working to obtain extreme differences, but it was noticed that, whilst with the rodinal there was a great latitude permissible in the exposure, that for the pyro-ammonia needed to be very accurate."

Before leaving this subject it is as well to point out that it is important in H. and D. testing to avoid the use of free bromide in the developer, and that even if in practice pyro-soda with bromide be used the speed of the plate will not be the same; but this does not get over the fact that some plates contain free bromide in the emulsion, and the effect of this is well shown by the following extract from the above-mentioned little work by Mr. Driffield:—"In an extreme case the influence of free bromide in the film is so marked as to absolutely necessitate a recognition of the varying speed of the plate as dependent upon the development factor to be reached. . . . The two strips, simultaneously exposed but developed for two and four minutes respectively, gave development factors of 0.73 and 1.0. Had there been no free bromide present the inertiae yielded by the two strips would have been coincident, and the speed, in consequence, constant; but

in this instance the inertiae are 0.75 and 0.22 respectively, so the speed varies from 45.3 to 154.5 for the two development factors obtained."

There is one point which has been advanced against the H. and D. system, and it is that by this method the period of under-exposure is entirely ignored, and yet it is this period which is to the practical worker the most important, for it is in this period that the "shadow detail" lies, and to which so much importance is attached by some, but it is obvious that the printing value of this is not so much dependent on the plate as the printing process that is used.

We have said sufficient to show that the question of plate speeds is not a simple one, and there is yet considerable work to be done in order to clear up many dubious points. Some years ago the Royal Photographic Society appointed a Plate Speeds Committee, but the results obtained by the various members were so ludicrously different as to lead to no useful result. Possibly, therefore, we may have to rely upon individual effort, but it would certainly be advantageous if a common agreement could be come to, so that the speeds of various plates could be directly compared.

SKYLIGHTS OF DIFFERENT STYLES.

THE old-time question of "what style light do you think best for making negatives" is still asked by many of our professional photographers, and some of them are of the best in the country. It is discussed at length by Felix Raymer in a recent issue of "Wilson's Photographic Magazine." Mr. Raymer's undoubted knowledge of the subject makes his remarks worthy of attention by all studio workers. He says: Taken as a whole, this matter should not bother one who has given the question close study, and who has a fair amount of artistic ability. If he wishes a certain effect in lighting it will be secured by him, it matters not from what source the light may come. On all sides we hear the questions what should the angle of a skylight be, what size, and of what kind of glass we should make it, and so on through the whole list. If there was any certain style light of a given size that was absolutely necessary to the making of good work, it would be pitiful to note the few in the country who could produce it, for there are not a half-dozen lights in the whole of the United States, so far as I know, that are of the same style, size, and of the same kind of glass.

Different Styles of Lights.

It has been my experience that the operator who has a good understanding of lighting, and knows what he wants when he goes in under the light, will succeed in getting that which he is after. To sum up in a nutshell the whole matter of different style lights, I will say that there are what we know as the double slant, single slant, and the perpendicular, or a large window. It has been my privilege to have worked under all these styles, and there are, of course, other styles that I have not seen; but, speaking from my experience with those I have tried, I feel confident that all of the other styles may be as easily controlled as those mentioned.

All Forms of Lighting the Same.

As to the style of light, it will make no difference in the effect of the lighting whether it be a single slant, double slant, or the window, so long as the one great principle of direction is carried out in the work. It is not the skylight that we are to consider, but the lighting, as it is to be made on the face. The lighting will never change. The same lighting can be made on all faces. The same effect can be secured any number of times, for it is made up of light and shade

through which run the half tones connecting the two, and this combination of light and shade will be the same at all times and on all faces, if it is made the same by the operator, the skylight having nothing to do with it except as a means to an end.

The Single Slant Light.

A few suggestions as to the manner in which each of the lights should be worked will perhaps make this statement clear. A single slant light measuring, say, twelve feet wide and eighteen feet high, starting about three feet from the floor, may be taken as an average of skylight construction. This style light usually drops into the room about four and a half feet from the top. To begin with, the light below the subject's head when a full length sitting is being made is absolutely useless, and not only that, but a hindrance to good work. I mean, the light is too low, and if I had such a light, the first thing I would do would be to cut off all of the lower part up to a foot or two above the subject's head when standing. This will make the light start about seven or eight feet from the floor.

Lighting from Below Useless.

The reason for this is that in portrait work there is never a time when we want the light to fall on the subject from beneath. If it does it will reverse all our ideas of nature. The light should come from a point above the subject, and from only one source. Now, it may be said in cutting off so much of the light the exposure will be increased. This may be true, but what if it is, provided we make our work better. There can be no work of a satisfactory nature where the light strikes up under the face illuminating the lower part of it more strongly than the upper portion.

The closing off of this lower portion of the light may be done with opaque curtains. After closing it off we will have a light measuring about twelve feet by twelve feet. If it is desired, such a light may be worked without other curtains, the only thing necessary being to place the subject at the right point or place in the room to get the light falling from the proper direction.

Correct Position of the Sitter.

The light being twelve feet wide, I would suggest that the subject be placed twelve feet from the light, out in the

room, and at a point directly over, with one end of it. This will allow all of the light to fall on the subject from the front. That is, all of the skylight will be in the front of the subject. Now, if the subject is turned slowly away from the light until all of the light leaves the shadow ear the lighting will be correct from any position the camera may occupy in the room. The reason for this is that you will be working the light on the square, so to speak. If it is twelve feet high and twelve feet wide and you have the subject posed twelve feet from it, the subject will occupy one corner of the square as it were, and the light falling towards the subject, will divide the square in halves. This will give a fall of forty-five degrees. In other words, and to make it plainer: If the light fell in a line from above straight down on the subject, it would be an angle of ninety degrees, and that line would represent one line of the square (the perpendicular line). But if the light fell from the side straight toward the subject, that would be the right angle of ninety, and the line thus formed would be the horizontal line.

Concentrating and Softening the Light.

Now, if this square is divided the light will fall from a half-way point, which will give the angle of forty-five degrees. As this square is reduced in size, the concentration of light and the accentuation of features will increase. But when it is reduced the subject must at the same time be moved nearer the light so as to hold him in the lower corner of the square. For example: If the subject is placed within five feet of the light, the opening of light in front of him should measure five feet wide by five feet high. If the subject is ten feet from the light the opening should be ten feet square, and so on. If stronger contrast is desired, the subject must be posed nearer the light, and the opening made smaller. In this way the light is concentrated on the parts that are desired to be emphasised. If softness is desired, the full square opening of the light should be used. Now, why the square, it will be asked by some. For the reason that it can be most easily managed. The wider the light, the softer the results, and to make them stronger the light will have to be curtailed off anyhow, to get them, so why not work with that idea in view all the time?

The Double Slant.

Now for the double slant. If it is worked in the same way, the effect of the light on the face of the subject will be identically the same. If your light measures twelve feet wide, pose the subject twelve feet from it, under one edge, so that all of the light falls from the front. Close off all light from the subject's head, and curtain the light so that it will be the same height as width, and the subject will be

in the lower corner of the square farthest from the light, as in the single slant, and the effect will be the same.

If more contrast is desired, make the square smaller, but do not fail to move the subject nearer the light so as to hold him in that lower corner of the square, bearing in mind that the smaller the square, and the nearer the light, the more concentrated the effect.

The Window Light.

If the light is an ordinary window, work it in the same way. If it is four feet wide, pose the subject four feet from it and at one edge, so that all the light is in front of the subject, and then make the opening measure four feet above the subject's head, closing off all light from below the top of the head. This will again place the subject in the corner of the square, and the result will be the same as in the other examples, except that they will be more concentrated and the features more accentuated, for the reason that the opening in the light was smaller.

Size of Light Makes no Difference.

So we arrive at the conclusion that it matters not what the size of the light. If worked in squares, one light will be as good as any other. If it is but eight feet wide, pose eight feet from it. If twenty feet wide, and it is desired to work it at its full square opening, the operating-room should be wide enough to pose twenty feet from it. It has been the accepted opinion for many years past that the light should measure a greater number of feet in height than in width, but personally I prefer a square, and should curtain it so that it would be square when lighting the subject, whatever its original shape. Nor do I believe in putting in a light so that it is lower than the height of a subject posed standing, for it has not been my experience that this lower light is ever used. I have never found a fine workman who wanted the light to fall from any other direction than that mentioned above.

Different Kinds of Glass Used.

As to the glass used in the construction of a light, it is merely a matter of personal preference. One operator will like strong, crisp, high lights, and will find clear glass best for his purpose. Another will like soft, delicate results, and will find ground or hammered glass more suitable. There is the whole matter in a nutshell. The crispness or softness of effect is not a principle of lighting. The operator may use his pleasure in making it, bearing in mind, however, that there should never be a time when his high lights are so high as to fail in showing flesh tints, nor the shadows so deep that they fail to show the detail. There is no place in portraiture for absolute white or absolute black. Let there be detail in both.

PHOTOGRAPHERS' ADVERTISEMENTS.

SOME COMMENTS BY AN OUTSIDER.

A PHOTOGRAPHER friend of mine one day murdered two people who had provoked him. He thought little of it at the time. Certainly he had no intention of going from bad to worse. But, sir, that was just what he did. In a few weeks he for the first time came home almost fuddled. Then he ceased to be truthful. He ceased to be punctual. He ceased to be neat. He took to cycling on Sunday. But why continue? In Sir Edward Clarke's historic phrase, "it grows more and more sad." Like many another man who began his downward career with a little murder or two which he thought nothing of at the moment, my friend sank and sank till at last he became worse than wicked. He became absolutely vulgar. He absolutely—*advertised*.

That story has one slight fault. It happens not to be true. Yet it may do for a start. I have an impression that it "touches the spot." If it does, let me re-inforce its impression.

Advertising need not be a matter of cheap-jack cajolery; of

screaming; of white-lie-ing. As Mr. Casey's useful articles in this journal have pointed out, it may be just a man's determination to do a triple justice—first, justice to some good work, or justice to the special power residing in him for producing that good work (an abstract consideration, no doubt; and yet do we not all talk of a man doing justice to his art or his craft; and we mean something by it); secondly, justice to himself; and, thirdly, justice to the public, who ought to benefit to the full through any man who has command of any special means of serving them. I believe photographers as a body do realise this. If they declared they did not, I should wonder if "hypo" was short for "hypocrisy."

Even John Morley!

Advertise; why certainly! Who does not? The other day I was reading Gladstone's biography, written by that model of severe restraint, Mr. John Morley. Even he once broke out

into an "ad." And always admiring him even amid any disagreements, I felt I loved him the more for this human trait. "One poor note the reader will not grudge," he writes in a foot-note, and he adds that in Gladstone's diary for the month which he is dealing with, he finds the entry, "Saw Morley, and commissioned him to see to —. He is about the best stay I have."

The Non-Advertiser: More Quixotic than Quixote.

I chanced to take up Cervantes's "Don Quixote" almost the same day. Cervantes was in gaol over some tax dispute (passive resistance, perhaps) when he wrote the "Don"; and he had the added mortification of seeing a paltry rival finding much greater favour with the public. So he works a word for himself into the Don Quixote story. He makes a priest and barber go over the Don's library to throw out for the bonfire any books which may have contributed to the knight-errant's madness. The last they come to is one by Cervantes, and thereon the priest, so far from bonfiring, makes a charming little speech about Cervantes and about the book which that author "proposes." The author gives himself a very ingenious advertisement, says the Quixote editor in a foot-note. Quite so. A hint from centuries bygone.

Mr. Disraeli's curl, Mr. Chamberlain's orchid, Mr. Keir-Hardie's one-time cloth cap in Parliament, Thomas Carlyle's style, and the latest actress's smile, do not these things all partake, more or less, of the nature of advertisement?

How our Leaders Work.

As I am writing comes to hand the shilling "Manufacturing Number" of the "Advertising World" (ordinarily sixpence, Granville House, 3, Arundel Street, W.C.). This journal or the "Advertising News" (one penny weekly, 21, Bride Lane, brought out by Mr. E. S. Day, the doyen of our advertising journalism) should be regularly studied. Try them in your (developing) bath. They float, and will help you to float. I see Elliott and Fry have a page in this "Advertising World." It is to illustrate how they as photographers assist advertisers. We see a sportsman shooting in the Highlands. He is waterproofed; he is holding his gun. It would suit a rubber man or a gunsmith. The subject (half-tone) is ruled around, and a design of feathers, conventionalised, with a bird which has been hit and two birds which have got off free, makes up a telling picture. There are simplicity, strength, and "keeping" in the whole. Note the wording, "We are now photographers for advertisers." These words are in black, panelled out, "The whole of our organisation and experience as photographers is behind this new department. We believe that goods well portrayed are goods half-sold. But they must be well portrayed. We will gladly send you samples of our work if you are interested in illustrations that sell goods."

Vanity: A Constant Market.

"Vanity of vanities, saith the preacher, all is vanity." And a good job, too, for the professional photographer. It means that he has a public always persuadable. You cannot persuade overcoats on to men in summer, nor pleasure-boat hiring on the Thames in winter, or in times of rain. You cannot persuade women to buy things long out of fashion. I say, a good job too, that vanity stays on for ever, because of the market it implies, and even for its own sake. You and I might have undiluted common sense, and insist on demonstrating the possession, till there was really no living with us. We might be

"Too wholly pure and good

For human nature's"—and the photographer's—"daily food."

Happily, we've a few redeeming faults, moderate vanity being one, and by no means the worst a man could have. It does not exclude gumpion. For instance, I, for one, am not very handsome; but I may be a degree less handsome in twelve

months' time; and why shouldn't I catch the passing phase? Better "the devil you know than the devil you don't know"; the face, the unfortunate face, even, of to-day than the possible face of a year or two ahead.

My Specific is "Be Specific."

Photographers then, of all men, are just the ones who never need wholly waste their advertisement seed. They've always a kindly soil somewhere. We are agreed so far, are we not? They, particularly, ought to advertise. The question then is "How?" The answer comes pat, "Specifically." I first lit on that jewel of wisdom for myself; and afterwards I chanced to handle the £2 2s. work Fowler has brought out in America entitled "Fowler's Publicity, an Encyclopædia of Advertising and Printing, and all that pertains to the public seeing side of Business," by Nathaniel C. Fowler, jun.; New York: The Publicity Publishing Company.

I turned up "Photography" in "Fowler." Sure enough, he had the same counsel, "Be specific." One day, says he, talk children's pictures; nothing else. Tell how you take their portraits instantaneously; you catch the most fleeting expressions; your children are children.

Other "Fowler" Hints.

Mr. Fowler says that the advertisements should never be less than two inches, and "occasionally half a column or more will be profitable during the season." "Advertise the taking of groups as a specialty." (I know the divided opinions as to this; but I go for the grouping.) "Let advertising stimulate a demand for pictures taken in costume." "The photographer should be an artist as well as a photographer, and should be able to pose people so that they will appear to the best possible advantage." "Make up an odd-size picture sometimes; give it a name, and advertise it under that title." "Any new finish can be properly advertised."

Hold on there a moment! What of the new adhesive dry mounting process? I think I can put any inquirer writing me at the office of this JOURNAL on to the way to benefit by this remarkable method, which I have most closely examined. Border effects are most easily obtained, and stretching of the prints is done away with. There are remarkable advantages in quickness as well. Surely there is advertising value here as well as mere saving of money, for those who are quickest on to it in their district.

As to prices, Fowler says: "Prices should be given unless the photographer caters only to the highest grade of people." Personally, I believe in giving some indication of cost. Circulars and advertisements which omit cost do no harm, I know; but we don't make our fortune by negatively doing ourselves "no harm." A little positive good is just as well once in a way.

The gentle art of getting free advertisements from editors is woefully neglected, though editors tell me they don't think so. Seriously, there must be many an occasion when the reporter would mention quite as an ordinary item in his report that the group on the squire's lawn, or at the vicarage, or the club house, was taken by So-and-So.

Fowler suggests some catch-words, not, I think, very catchy; but there's something in "Cross babies taken;" "Art in photography;" "Natural photography;" "He wants your picture;" "She wants your picture;" and there is audacity in his "I take you for yourself"—there would be still more in "I take you for—your money."

The Incident Advertisement.

What of a short incident in small type to head your advertisement or circular? As this:—

"Alderman Sir Robert Carden met a bright-faced boy in the City. Something made him stop. He fumbled in his pocket; then gave the boy a shilling. 'Thank'ee, sir, what's it for, sir?' 'Dunno, boy; dunno at all. Only, you look so jolly.' Exactly, and a bright young face with happy, instantaneously

caught expression, looking out at us from our wall at home, especially if it be the face of our own youngsters, would constantly refresh our hearts as this boy's jolly face cheered up the old alderman."

Or, again, this line, intrinsically pleasant, and having also allusive interest:—

"It must have been dear and refreshing to a father's heart: 'Mr. W. E. Gladstone, speaking in the House in praise of a speech which Mr. Austen Chamberlain, then new to the House, had just made, and made in his father's hearing.'"

Then the advertisement might proceed to enforce how dear and refreshing to a father's and mother's heart the child's face, particularly the face of the absent child, might be.

Human Interest.

You see my point—human interest. That is what the photographer has in common with the public. Human nature is a great many things. Incidentally it is a small gold-mine—for the shrewd advertiser.

FRANK COLEBROOK.

[The conclusion of the above comments, suggested by Mr. Casey's articles, will appear next week.—Eds. B.J.P.]

THE WEEK IN HISTORY.

The Ancient of Days.

PROBABLY few of my readers have not read of that dodge whereby a negative is helped in printing by concentrating the sun's rays upon part of it with a lens. This expedient is so old as to renew its youth periodically, when it starts its tour once more round the foreign photographic journals as a method hot from the brain of your latter-day enthusiast. Probably the author of the paragraph adapted, or, as the playwrights say, "thickened," it from THE BRITISH JOURNAL OF PHOTOGRAPHY of over forty years ago, for on April 15, 1863, there it is in these columns, and then, as now, the author dwells upon the virtues of the venerable "wheeze." "Now when our pressure-frame containing the negative or the sensitised paper is exposed, we furnish ourselves with a burning-glass by means of which we guide what may be called the luminous point to those parts of the negative most opaque to light . . . and the effect of this condensed light is something so energetic that the most opaque parts of the negative, thus lighted, have acquired the necessary exposure before the more transparent portions are sufficiently printed. We have been able, in this way, to reproduce more delicate details than by ordinary light—details which would in fact have become lost in the density of the negative."

Photography in Embryo in 1897.

Thursday in next week (April 20) is the day on which Nicéphore Niépce was narrating his earliest photographic experiments only twelve years short of a century ago. Writing to his brother Claude he says:—"I believe I have told you that I have discontinued the use of silver chloride, and I believe you

know the reasons. I was much perplexed to replace it until I read in a chemical book that "résine de guaiac," which is yellowish grey in colour, becomes a beautiful green when exposed to light, and thereby acquires new properties—viz., it becomes less soluble in alcohol. I therefore made a strong solution of this resin, and noticed that when spread as a film on paper and exposed to light, it became emerald green in a short time, but that when a film as thin as was necessary for my purpose was used, it did not exhibit the least difference in solubility towards alcohol; so that after many experiments I have become convinced of its unsuitability, and have given it up.

The "résine de guaiac" which Niépce used is evidently the guaiac resin of the West Indies. Paper treated with tincture of this material becomes blue or green in the light, but Niépce did not observe that these colours are destroyed on further exposure, particularly to orange rays.

Niépce stuck close to the resipuous bodies in his search after a "resist" for a metal plate, and three months later he was telling his brother:—"I have just been analysing the gum resin of guaiac with the object of isolating that part of it sensitive to light. I have already found that the portion of the resin soluble in water does not possess this singular property, and that the resin deprived of this portion is much more sensitive. Also this resin still contains a constituent insoluble in both water and alcohol—a fact which enables me to obtain it perfectly pure. If I find that in this state its combination with oxygen by the aid of light renders it less soluble in alcohol, I shall have made a great step towards the solution of the problem."

HISTORICUS.

WILD-GAME Photography.—The difficulties experienced in wild-game photography are discussed in a recent issue of the "New York Tribune," and although the opportunities for this kind of sport are not so plentiful in this country as in America, the observations in the article referred to make interesting reading. For successful picture making the photographer must approach to within five or ten yards of his subject, and within twenty or thirty yards with a long focus or telephoto, the latter further requiring time exposure and the handling of an awkward 24 in. bellows. Then, after crawling for possibly 200 yards or more under cover and against the breeze, and gaining a good close-range view of his quarry, he must consider the focal distance, the light and the motion of the animal, and regulate the scale, diaphragm, and speed accordingly. All of these adjustments in readiness, the question rises how to make the exposure without detection. There are numerous possibilities of accident or neglect, all of which lead "knowing ones" to admit that it is more credit to secure a single photograph of wild game than to slaughter a whole herd of animals. The methods employed by the few successful wild-game photographers differ materially, according to localities, the special habits of the animals, and the individual judgment of the man at the

camera. Mr. A. G. Wallihan, a pioneer in the field, obtained his mountain-lion, bear, and bob-cat negatives by treeing the animals with dogs. He secured his antelope pictures in the fall before the early snows afforded liquid refreshment on the north hillsides and when the watering-places were scarce and not easily located. One of the most prominent wild-game photographers, and the only one who has employed successfully the flashlight for this purpose, is Mr. G. Shiras, of Pittsburg. For many years his summer outings have been spent in Northern Michigan, where he has given up his time largely to photographing wild deer at night. With a stereoscopic and a four by five camera focussed at twenty and twenty-five feet, and arranged beneath a jack-lamp and flash-pan, he has invaded the inlets and swamps of this part of the country, paddling cautiously along the shores against the breeze. Sometimes in company with a skilful guide he thus has explored the haunts of the deer for as long as a week without making a single successful exposure. Arranging his cameras to cover practically the same field as the jack-lamp, the difficulty lies in locating the deer and approaching within the required distance. But once having determined these points, the flash is discharged, when the alarmed deer is off before the smoke has cleared away.

HOME-MADE LANTERN PLATES.

CONSIDERING the general excellence and moderate cost of the commercial lantern plate, it is probable that comparatively few would care to undertake their manufacture at home, but those who have the spare time and inclination will find the preparation of a simple emulsion and the coating of a few dozen lantern plates not only of considerable interest, but of educational value as well. Mr. S. H. Wratten, at the Croydon Camera Club on the 5th inst., very clearly showed and explained how a slow lantern plate might be made without difficulty, and, judging from the slides which were afterwards thrown on the screen, of first-rate quality also.

A Simple Formula.

The following was the formula and method of working recommended by Mr. Wratten:—40 grains of Nelson's No. 1 gelatine are taken and rinsed in two or three changes of water, to remove adhering dirt and any acidity present, and placed in a clean jam-pot with the addition of four ounces of distilled water. The mixture is gently heated, stirring the while, and the following added and thoroughly incorporated:—

Ammonium bromide	110 grains.
Sodium chloride (ordinary table salt)	30 grains.
Hydrochloric acid (1 in 10)	10 minims.

The ammonium bromide should be tested for acidity, and, if acid, neutralised with ammonia. In a clean graduate next dissolve 200 grains of silver nitrate in one ounce of distilled water. The foregoing operations can be conducted in ordinary daylight; the subsequent ones must take place in the dark room, but a very bright orange light can be employed, and with advantage, without any fear of fogging the emulsion.

Making the Emulsion.

The silver solution is now added very gradually in a fine stream

to the solution first made up, which is maintained at a temperature of 125 degrees Fahr., stirring well with a glass rod all the time, and the mixture digested at a temperature of 150 degrees. Fahr. for ten minutes; 175 grains of a good hard gelatine (previously soaked till quite soft, and rinsed in two or three changes of water) are next added, and when dissolved the bulk of the liquid is made up to eight ounces with distilled water. The emulsion, which should, by transmitted light, appear of a ruby colour, is allowed to set, and when firm cut up with a bone or ivory paper-knife into small squares and tied up in a canvas bag of fairly open mesh, the bag being suspended in a pail of water for half an hour, the water being changed every five minutes. This will remove the soluble salts. The surplus water is then well drained off, the emulsion remelted, filtered through any suitable fabric, and two grains of tannin finally added.

Coating the Plates.

For coating the plates an ordinary stoneware teapot will be found most suitable. The glass plate, which must be scrupulously clean, is conveniently held by a pneumatic holder, and the emulsion, at a temperature of about 100 degrees Fahr., poured on, and made to flow to each corner by gently tilting the plate, any air bubbles that may form being immediately conducted to the edge with the glass rod. The plate is now carefully slid on to a level and wet surface—a piece of levelled plate-glass answering very well—and allowed to set. In hot weather it may be necessary to cool artificially the levelled slab with ice. When set, the plates are, one by one, removed to a drying cupboard, through which a current of warm dry air is allowed to circulate, and stacked at an angle of 45 degrees, at least four inches apart to ensure even drying. The plates will be found to work well with any reliable transparency developer, and if carefully stored will remain in good condition for a considerable period, six months at least.

ARTISTIC Perception.—At the annual meeting of the Yorkshire Photographic Union on Saturday last Mr. Alex. Keighley gave an address on "Artistic Perception," in which he claimed that the faculty to see the beautiful in nature and in art was quite a thing apart from the mere physical sense of sight. Mankind generally did not look for those truths and qualities which artists looked for, and were too often content to use their eyes as channels for mere information. Seldom thinking about beauty, and not looking at nature with any reference to art, they scarcely saw the æsthetic aspects of nature at all, or only in a very imperfect way. There were many people with cameras who were ready to photograph any object they met with, providing it were a definite object—a church, a castle, a bridge, or something else to which a name could be put, and the work was done with little thought as to obtaining the most pleasing result. Such persons had not learned to see, in the artistic sense of the word. The artist, like the poet, was said to be born, not made, and in some individuals the sense of artistic perception seemed to be largely innate, while in others it existed only in a minor degree. But whatever might be the natural endowment, real and permanent success as an artist could only be achieved by careful and constant study of nature and of art. However much one might appreciate a beautiful landscape, his appreciation would be enhanced if he looked at it with the eye of an artist, trained to understand the effect of form, light and shade, and knew why it was beautiful. He advised the budding pictorial photographer to take every opportunity of visiting picture galleries, exhibitions of works of art of all kinds, and of studying art-books, and art-magazines, and the photographic journals which gave attention to the art side of the subject. Better still, he should practise any of the graphic arts. In conclusion, he urged upon photographic societies

the desirability of paying more attention to art culture, instead of devoting themselves wholly to the study of plates, paper, and methods.

"**OZOTYPE in Gelatine and Gum,**" Mr. Manly's practical guide to the modifications of this process, has appeared in a new fourth edition, which contains certain new formulæ, including a new acid reducing bath which can be kept for some considerable time. There are also directions for sizing papers, spotting and mounting prints, etc. The little book is sent free by the Ozotype Co., 1, Weedington Road, Kentish Town, London, N.W.

SHEFFIELD Photographic Society.—The next exhibition of this Society will be held from October 28 to November 4. The Joint Hon. Secretaries are: J. W. Charlesworth, 1, Joshua Road, Sheffield, and James W. Wright, 62, Vale Road, Sheffield. The prospectuses will be ready about September 1.

BRITISH Association Geological Photographs.—The geological photographs committee of the British Association has completed the first series of published photographs from the collection housed in the Museum of Practical Geology, 28, Jermyn Street, S.W. There are twenty-four photographs in the present issue, all of great interest, showing much skill in technique, and considerable artistic power in the choice of the point of view from which the objects were taken. They treat of a variety of subjects, chiefly the action of wind and rain, frost and ice, and sea-waves, igneous intrusion, the character of sedimentary rocks, and structures due to faulting and folding. The series issued to subscribers and just completed consists of a selected number (72) of photographs, taken from negatives generously lent by their owners, and furnished with descriptions by many of the leading geologists of the day.

Photo-Mechanical Notes.

A New Dry Plate for Process Work.

THERE are probably not more than half a dozen firms in the photo-engraving craft that rely exclusively upon dry plates for making their negatives, and it is certain that if ever they are to become popular such plates will need to be isochromatic. With characteristic enterprise Messrs. Wellington and Ward are the first to fulfil this requirement, and have placed upon the market a colour-sensitive process plate under the name of "Ortho Process."

From practical trial we find this an excellent plate; it is of fair rapidity (much quicker than the "Etching" plate); it develops quickly, giving great density; it is entirely free from fog, giving good gradation, while the deposit is of very fine grain, and the plates are exceptionally clean between the dots. As regards the colour sensitiveness, from a photograph of the arc spectrum it would appear that this is conferred by the erythrosine type of dye, since there is the familiar gap in the blue green, and great sensitiveness in the yellow green, extending as far as the D line. The ratio of yellow to blue sensitiveness is about 1 to 4, which is rather higher than the average isochromatic plate.

It will thus be seen that this plate is a decided acquisition to the process worker, as not only will it do all that the ordinary plate will do, but the operator may use a suitable colour-filter when making screen negatives from coloured originals, and he will then not only have better values in his reproduction, but get a good printable dot at the same time, which has been almost impossible hitherto. As the price is the normal 2s. 3d. per dozen for half-plates, we see no reason why plates of this kind should not replace entirely the ordinary process plate now used.

Care of the Half-Tone Screen.

Some cautionary notes, which we suspect are somewhat old, are quoted by the "Inland Printer" from "Le Moniteur de la Photographie." They are worth repeating, however, as many photo-engravers seem to disregard the inherent liability of a screen to deterioration. Explaining that the cover glass of the screen, owing to the high temperature and pressure under which it is cemented, is in a state of tension, the writer points out that the least perceptible rise of temperature, in softening the balsam, causes the glass plates to return to their primitive form, leaving bubbles between them, which are very brilliant when examined by reflection. Screens which have been in use some years are less subject to this defect than new ones, and withstand the effects of a high temperature without being loosened. Consequently, new screens should be kept in as cool a place as possible and tightening them too much in the screen holder avoided, as pressure tends to produce deformation which may loosen the balsam. Certain precautions must be taken in cleaning screens. A scratch on the surface through clumsiness may render a screen useless, or, at least, necessitate tedious retouching on each of the negatives obtained. If the scratch is very light, it will suffice to have the surface polished by a specialist. Usually, at time of use, the two sides of the screen are polished with a silk rag or piece of tissue-paper. Thus the glass is greatly electrified, and the screen becomes covered with a regular cloud of atmospheric dust which is attracted. Thence the necessity of not polishing the dry glass, but employing a wet rag. It is, however, to be noted that any solvent of balsam, especially alcohol, should never be allowed to remain on the screen, as it would enter through the joints.

Having removed the screen from the apparatus, place it in its box, or on a cushion of paper or fine linen, and then dust it lightly

with a very soft badger's hair brush. A piece of cambric is now employed, moistened with a few drops of alcohol, to gently wipe the surface over. Another rag is used for drying, and to prevent electrification, breath upon it before touching the screen. Press very moderately and pass the rag slowly over the surface.

If metallic stains make their appearance on the surface, owing to the fall of some drops of nitrate of silver and subsequent reduction, wipe them off with a piece of fine cambric slightly moistened with nitric acid in double its volume of water, and then, before cleaning as above, wipe the surface with another rag slightly dampened with ammonia. By observing these precautions there will be no danger of the least accident.

Absorbent Properties of Printing Papers.

The absorbent properties of paper for the oily medium of printers' ink do not correspond exactly with the absorption of aqueous inks; e.g., certain soft-sized papers absorb the oil of printers' ink no more readily than hard-sized papers. The quantity and ink-resisting power of rosin sizing (according to a paper by P. Klemm, abstracted in the "Journal of the Society of Chemical Industry") have no influence on the absorbent properties of the paper towards oil, since rosin is easily wetted by oil. Gelatine hinders the absorption of the oil, as is shown in the case of coated papers, but mineral matters are favourable. The structure of the paper, as determined by the nature of the fibres and their behaviour on beating, is also an important factor. The denser the structure the less oil-absorbent is the paper, since the fibre substance itself resists oil, but not water; the absorptive powers of different papers towards oil do not vary so widely as towards water. When paper is printed, the oil-varnish medium distributes itself between the pigment and the paper, according to the relative absorptive powers of each. If the paper be too absorbent the medium may be withdrawn from the pigment to such an extent that the latter rubs off. This effect will vary according to the thickness of the oil-varnish. With very absorbent papers it may be necessary to employ a thicker varnish, or else a certain excess of varnish, which will fix the pigment after the paper has absorbed as much as it is capable of. The elasticity of the paper is of greater importance than the porosity on which the absorptive power depends. It is desirable that any inequalities and pores in the sheet should be capable of being evened up by the pressure during printing; the good printing qualities of coated "art" papers are due to the uniformity of the surface, and their deficient absorptive power is of little importance. One great advantage of a highly porous paper is that the access of air is facilitated, and the varnish dries more rapidly; this is of greater importance than a high absorptive power. A drawback of high porosity, however, is the liability of the oil to penetrate to the back of the paper, and show the printing on the reverse side.

UNDER the auspices of the Otley Camera and Art Society, an exhibition of picture postcards and almanacs was held at the Mechanics' Institute on Saturday afternoon, when upwards of £12 was given in prizes. The competition brought forward 292 exhibitors, and the large hall was filled with an interesting collection. The exhibition was opened by Mr. E. P. Arnold-Forster, who said that it was very fitting that the first exhibition of that kind should be held at Otley, the home of the valentine, which was now becoming obsolete. The subject of postcards led him on to speak of the functions of the Post Office, and he said he hoped that at some time there would be a free postage in the United Kingdom. This was no more impossible than a universal penny postage in the British Empire had seemed when he had the temerity to advocate it ten years ago, and yet to-day it was an accomplished fact.

Exhibition.

FOURTH PHOTOGRAPHIC TRADE AND PICTORIAL EXHIBITION.

As announced in our last issue, the Portman Rooms Exhibition opened its doors to the public on Friday last, and disclosed a collection of photographic apparatus and materials representing the very considerable progress which has been made by manufacturers since the previous exhibition in 1902. The first impression is the advance in tasteful decoration adopted by the stall holders. Messrs. Elliott and Sons, of Barnet, whose stall faces the entrance, are the first to create that feeling, which is strengthened by the decorative designs adopted by Houghton's, Ltd., the Rotary Photographic Co., Ltd., A. and M. Zimmermann, and Burroughs Wellcome and Co., to name only a few of the many exhibitors who have expended care and money on the artistic presentment of their wares. The full list of the exhibitors appeared in our last issue, and we need not, therefore, repeat it. The visitor will find that, with a few notable and important exceptions, such as Messrs. Kodak, Ltd., Ilford, Ltd., Imperial Dry Plate Co., Ltd., Marion and Co., Ltd., J. J. Griffin and Sons, Ltd., etc., etc., the photographic trade obtains a very efficient representation at the hands of the organisers of the exhibition. A casual stroll round the seventy stalls affords a convincing demonstration of the large place photography has made for itself in modern industry. The variety of the modern photographic manufacturers must be surprising to those who have not watched the entrance of the amateur into the circle from which the makers of apparatus and materials draw their customers. But the professional equally has had the attention of the trade, if not in the provision of an infinite and ever-changing variety of accessories and fittings, at any rate in the improvement and cheapening of his appliances. The Portman Rooms, therefore, during the two days on which they remain open—they close to-morrow at 10 p.m.—may well be visited by any photographer who can spare an hour. In addition to the purely trade exhibits, there are lantern demonstrations of cinematography and of Dr. Miethe's colour photography. Of the latter, we ought to say, in qualification of our notes last week, that the operators apparently were not able to adjust the rheostats governing the three arc-lights to give a steady and equal illumination to each of the three monochromes. The result was that many of the effects were visible only for a few instants, and the spectators obtained occasional glimpses only of what colour photography was capable of. Dr. Miethe's series, however, contained a number of slides which impressed us as marvellously faithful to the original scenes.

Demonstrations are an attraction at one or two stalls. Messrs. Thomas Illingworth and Co., Ltd., show the simplicity of "Zigo" paper, and exhibit some striking examples of the paper which "needs no toning." The Quincey Photo-Development Co. draw a crowd to witness the development of plates and films in the various Quincey boxes, and the latest form of their apparatus is shown, and seen to embody improvements in the matters of inspection of the plate during development—the whole can now be seen—and in the certain transference of the roll film, exposure by exposure, into the developer.

Among printing processes the Barnet papers make a strong and varied show, which includes a number of results by the new "Owl" toner. The Paget Prize Plate Co. exhibit a brilliant collection of work, chiefly on self-toning collodion paper, of which they are just issuing a new brand—on a cream matt paper—which seems specially deserving of investigation by professional photographers. Paget self-toning papers, further toned by a short immersion in the platinum bath, make a very powerful appeal for this simplification of printing methods. Prints in gold, silver, and copper effects are shown by the

Métotype Co., Ltd., whose specialties ought to attract enquiries from professionals. The range of tones on "Pan" paper is a striking thing with the Bayer Co., whose chief show, of course, is their many chemical preparations.

NOVELTIES FOR THE SEASON AT THE PORTMAN ROOMS.

One object of our tour of inspection was to discover new goods coming, or lately come, upon the market. As most of these will sooner or later, be more fully announced in these pages, we content ourselves now with a brief mention of some notable newcomers which are on view in the Exhibition:—

"RED SEAL" plates, a new ultra-rapid plate at popular prices. The "Barnet Book of Photography," new edition (Elliott and Sons, Ltd. Barnet).

Ball and socket head for cameras, with one motion to tilt the camera, and a second separate one to turn the camera. Also a ball and socket head adaptable to any camera turn-table (J. Ashford Birmingham).

"Card Index" systems of storing negatives and prints with boxes, cabinets, etc., for carrying it out. A comprehensive scheme which should be valuable to the professional (Houghtons, Ltd., London).

Ensign non-curlable film (Houghtons, Ltd., London).

Magazine reflex cameras, price 30s. Folder portfolio mounts in art styles (Chas. Tyler and England Bros., London).

Beck Multiflex lantern objective, embodying in one instrument focal lengths of 6, 8, 9, 10, 12, 14, and 16 inches (John Wrench and Son, London).

Reflex hand camera with focal-plane shutter, etc., price £5 (O. Sichel and Co., London).

Rotary carbon stripping film (Rotary Photographic Co.).

New Ernemann focal plane cameras, and the "Kino" amateur cinematograph apparatus (Chas. Zimmermann and Co.).

New "Agfa" developers and specialties (Chas. Zimmermann and Co.).

THE PICTORIAL SECTION.

The competitive pictorial section of the Exhibition has been well supported, and a collection of 257 framed prints, and 25 sets of lantern slides are on view. The pictures are well displayed on screens, and include a great number of well-known works by members of the Hackney Photographic Society, the hon. secretary of which, Mr. W. Selfe, was responsible for the organisation of the section. Mr. H. W. Bennett was the judge, and the following is the award list:—

Gold Medal for best picture in the Competitive Section.—No. 35, "A Stormy Sunset," by W. A. I. Hensler.

Class A.—1 (silver plaque), No. 10, "A Golden Sunset," by Wm. Rawlings; 2 (silver plaque), No. 3, "Winter," by Thos. Wright.

Class B.—1 (silver plaque), No. 123, "Lady Disdain," by Marian Silverston; 2 (bronze plaque), No. 94, "A Dutch Fisherman," by Wm. Rawlings.

Class C.—1 (silver plaque), No. 157a, "The Last Rest," by Arthur Marshall, A.R.I.B.A.; 2 (bronze plaque), 153, "The Undercroft Wells," by G. Catherall.

Class D.—1 (bronze plaque), No. 174, "Iris," by J. Hummel; 2 (bronze plaque), No. 164, "Chrysanthemums," by E. Seymour. (Silver plaque withheld.)

Class E.—(Lantern Slides).—1 (silver plaque), "Time of Sunshine," by Rev. H. W. Dick; (first bronze plaque), "Daffodils," by W. H. Goy; (second bronze plaque), "Sunshine and Shadow," by F. E. Rooft.

WATFORD CAMERA CLUB.—The last meeting of the session was held on the 31st ult., at the headquarters, 100, High Street, Watford. Mr. W. D. Welford gave an illustrated lecture on "Photography in General."

FORTHCOMING EXHIBITIONS.

April 7-15.—Photographic Trade Exhibition, Portman Rooms, Baker Street, London, W. Manager Pictorial Section, W. Selfe, 70, Paragon Road, Hackney, London, N.E.

April 7-May 8.—International Artistic Exhibition, Berlin. Director, Herr Franz Goerke, Maassenstrasse 32, Berlin, W.

April 24-29.—Redcar and Coatham Literary Institute Photographic Society. Secretary, W. Hildrith, 42, Newcomen Street, Redcar, Yorks.

April 27-29.—Southend-on-Sea Photographic Society. Hon. Sec., J. Archer, 24, Ashburnham Road, Southend-on-Sea.

April 28-29.—Watford Photographic Society. Hon. Secretary, C. J. Trevarthen Ashcroft, Bushey Hall Road, Watford.

May 1-31.—International Exhibition of Photographic Picture Postcards, concurrently with the 10th Salon. M. le Secrétaire-Général du Photo Club de Paris, 44, Rue des Mathurins, Paris

May 9-10.—Ballarat Camera Club. Hon. Secretary, G. Montgomery, 201, Sturt Street, Ballarat.

May 9-13.—Warrington Photographic Society. Hon. Secretary, A. C. Smithson, 13, Chester Road, Warrington.

May 10 to June 19.—Salon of the Photo Club de Paris. Secretary, Paul Bourgeois, 44, Rue des Mathurins, Paris

July 4 to August 12.—Northern Photographic Exhibition. Secretary, F. G. Issot, 62, Compton Road, Harehills, Leeds.

September.—Royal Photographic Society, New Gallery, Regent Street, London, W. Secretary, J. McIntosh, 66, Russell Square, London, W.C.

October 28-November 4.—Sheffield Photographic Society. Joint Hon. Secretaries, J. W. Charlesworth, 1 Joshua Road, Sheffield, and James W. Wright, 62, Vale Road, Sheffield.

November 21-25.—Southampton Camera Club. Hon. Secretary, S. G. Kimber, Oakdene, Highfield, Southampton.

December 1-6.—Hove Camera Club. Hon. Secretary, A. R. Sargeant, 55, The Drive, Hove.

December 12-20.—Southsea Photographic Society. Hon. Secretary, F. J. Lawton, 5, Pembroke Road, Portsmouth.

FORTHCOMING COMPETITIONS.

May 15.—Burroughs, Wellcome, and Co. Money prize for negatives developed with Tabloid Pyro-Metol developer.

May 15.—Warwick Dry Plate Co. Money prizes for prints from negatives on Warwick plates. Open to members of Photographic Societies only.

September.—Kodak. £400 in prizes for results on Kodak products. Kodak Ltd., 57-61, Clerkenwell Road, London, E.C.

Commercial & Legal Intelligence

At the Birmingham County Court, Mr. Registrar Lowe made a receiving order in the matter of Walter Elliot Lander, photographer, residing at 86, Belgrave Road, and carrying on business at 104, John Bright Street, Birmingham.

POOR Postcards.—At the Manchester County Court, on Wednesday of last week, the Grove Photographic Company, Lime Grove, Long-sight, sued Mr. G. Worthy, also of Lime Grove, to recover £3 in respect of photographic postcards, which had been taken by the former. After the Judge had capiously criticised the postcards, he said he could not say the articles he had seen formed a reasonable compliance with the terms of the contract. He gave judgment for the defendant with costs.

NEW COMPANIES.

F. C. MORGAN AND CO., LIMITED.—Registered March 28. Capital, £2,000 in £1 shares. Object: To adopt an agreement with F. L. G. Kollmorgen, B. Weissert, and I. L. Ashe, and to carry on the business of art publishers, newspaper proprietors, photographers, engravers, etchers, printers, publishers, dealers in chemicals and photographic apparatus, etc. No initial public issue. Registered without articles of association. Registered office: 4, New Union Street, Moorfields, E.C.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

The following applications for Patents were made between March 27 and April 1, 1905:—

CINEMATOGRAPHY.—No. 6,436. "Improvements in cinematograph cameras." Max Hansen, 22, Nachod Str., Berlin W., 15.

APPARATUS.—No. 6,514. "Improvements in photographic apparatus." Samuel Henry Adams and Colin Henry Adams, care of Adams' Hydraulics, Ltd., Scotswood-on-Tyne.

PLATES AND FILMS.—No. 6,657. "Apparatus for working with photographic plates and films in any place." Wilhelm Vogel, 6, Bream's Buildings, Chancery Lane, London.

RAPID PHOTOGRAPHY.—No. 6,705. "A machine for taking and finishing a photograph on paper or other substance in from two to five minutes." William Ricketts, 80, Rothbury Street, Scarborough.

MERCURY-VAPOUR LAMPS.—No. 6,755. "Improvements in or relating to mercury-vapour electric lamps." Charles Andrew Lee, 24, Cleveland Square, Hyde Park, London.

COLLODIONS.—No. 6,783. "Improved means for filtering and drawing collodions and cellulose solutions." Société Desmarais and Georges Morane, and Maurice Jules Armand Denis, 7, Southampton Buildings, Chancery Lane, London.

PIGMENT PRINTS.—No. 6,877. "A new or improved process and means for producing pigment pictures, single or multi-coloured photographs, and plastic or printing plates with a silver salt or like emulsion." Jules Meszados, 18, Buckingham Street, Strand, London.

COMPLETE SPECIFICATIONS ACCEPTED.

Specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

PRINTING FRAME.—No. 10,597. 1904. The frame is made in the usual way, but instead of the back being separate from the frame it is joined to it by a wire passed through the centre of both hinges, or a series of metal straps to form hinges, the wire being long enough to be bent at right angles to both sides of the back, and pivoted on each side of the frame near one end; or the wire may be made in two parts, one end of each part being bent so as to form the centre of an ordinary butt hinge, the other end of

each part being pivoted to the sides of the frame, as before described, thus making the back an absolute fixture to the frame, and by the same means removing all risk of moving the sensitised paper during examination of the print. The figure shows a side view of the frame, with the back partially lifted away for the insertion of the negative and for the examination of the print. The part B. of the hinged back is raised, whilst the other part is held in place by the wire. John Baty, 124½, Wills Street, Lozells, Birmingham.

FRAMES FOR PHOTOGRAPHS.—No. 10,548. 1904. A form of frame, the supporting strut of which is connected to a base plate by means of a flexible joint. The strut is attached by a flexible

connection, and the plate carrying the leg is fixed to the back of the frame by a pivot connection." Frank James Hall, New Zealand Avenue, Barbican, London.

STEREOSCOPIC POSTCARDS.—No. 5,949. 1904. Cards bearing stereoscopic pictures and means for examining the same. The pair of stereoscopic pictures is printed from half-tone blocks, the impression from each block being superimposed upon the other, or nearly so. The colours that are complementary to each other, such, for instance, as red and green, are used in the printing, one block being printed in one colour, and the other block in the other colour. In the remaining part of the same card are made two holes, which are covered with transparent red and green media, respectively; or with transparent media or any other two colours that are complementary. To examine the stereoscopic view, the perforated portion of the card is to be detached and used as a stereoscope, one eye looking through the red medium and the other eye looking through the green medium. Theodore Brown, 34A, Castle Street, Salisbury; and Ernest Osman Brown, 9, Queen's Road, Bournemouth.

SHUTTER ADJUSTMENT.—No. 6,974. 1904. Methods of carrying out a suggestion made in the Watkins' patent, No. 5,737, 1900—viz., that, instead of making two separate adjustments of shutter and lens aperture, the setting of the latter should automatically adjust the former to the proper speed. In devising appliances for this purpose a diaphragm is constructed, such that the area of the iris aperture varies in the same proportion for equal amounts of the rotary movements of the iris plate slide. This movement is accomplished in several ways, two of which are shown in the accompanying figures. The claims are: (1) The combination of an iris diaphragm with means for actuating it in which equal displacements of the actuating means produce a constant rate of variation of the area of the aperture, substantially as described. (2) An iris diaphragm, the leaves of which are actuated by a rotatable iris plate in such a manner that the angular displacement of the iris plate is proportioned to the logarithm of the area of the resulting aperture, substantially as described. (3) An iris diaphragm having the leaves formed substantially as shown in Fig. 1 for the purpose specified. (4) An iris diaphragm, the leaves of which are actuated by mechanism constructed and operating to effect the purpose herein specified, substantially as described, with reference to Fig. 4 of the accompanying drawings. (5) A lens mount for compound lenses, having an iris plate slide controlling the iris aperture in such a way that a common scale can be used for lenses of different foci, substantially as described. (6) A lens

Fig. 1.

Fig. 4.

(From patent specification).

mount provided with scales for the computation of exposures, in which one of the moveable scale slides is arranged to alter the area of the iris aperture in such manner that successive equal displacements of the scale slide either doubles or halves the area of the iris aperture, according to the direction of motion of the slide. Alfred Watkins and Charles Godfrey Woodhead, Imperial Mills, Hereford.

PROJECTION LANTERNS.—No. 5,839. 1904. An optical lantern, specially for use with the Nernst electric lamp, the filaments of which are mounted to a porcelain or other insulatory plate. The construction of the lantern body is tubular, and, as seen in the figure,

FIG. 1.

admits of projection, horizontally or vertically. The claims are for a lantern of this kind in combination with a Nernst lamp. Robert William Paul, 68, High Holborn, London.

New Apparatus, &c.

The No. 4 Screen Focus Kodak. Made by Kodak, Ltd., 57-61, Clerkenwell Road, London, E.C.

There are many camera users who would like to have a roll film camera, but who, from the class of work they affect, or from custom want to focus on the ground glass most of the exposures they make. The same demand is made by many workers commencing photo-

The Screen Focus Kodak, showing double extension.

graphy. It is to meet this growing demand that the enterprising Kodak Company has introduced an important addition to its already large family, and the special claim made for the No. 4 Screen Focus Kodak is that it allows the operator to focus every picture, whether on roll film or plates, for both of which it is adapted. This Kodak is a clever combination of roll film and glass plate camera. It is in two parts—the camera proper and the roll holder. The latter is secured to the camera by a catch and bolts, and can be made to swing up so as to carry the film out of the focal plane, and allow a glass screen to be placed across the open back for focussing purposes. The possibility of focussing each exposure, whether on roll film or plates, is the chief feature of the new Kodak. In order to do this it is only necessary to pull out a shutter which is carried in the camera back, and insert it in a slit in the holder immediately in front of

the roll film. Its function is to protect the film by rendering the roll holder light-proof, and to make possible the raising of the roll holder away from the focal plane. The roll holder is secured to the camera by a spring catch, operated by a button, which cannot be moved

The Screen Focus Kodak, showing roll holder raised and ground glass in position.

unless the shutter, referred to above, is in position in front of the film. The possibility of fogging the film by separating the roll holder and the camera, while the film is unprotected, is therefore entirely obviated. The shutter being in position in front of the film, the concealed button at the lower right-hand side of the camera is pressed, and the roll holder raised on the pivot bolts until it catches in a horizontal position, disclosing the open back of the camera across which is affixed the ground glass screen.

The raised film holder now serves the purpose of a focussing shade. After the picture is focussed, a pressure on the catch releases the film holder, which is then swung back into the focal plane, the cut removed, and the exposure made in the usual manner.

The Screen Focus Kodak may be quickly converted into a plate camera of high efficiency by detaching the roll holder and affixing a special plate adapter provided with a ground glass and spring focussing hood. Having focussed the picture the plate holder is slipped in between the spring ground-glass frame and the camera, and the exposure made.

The general equipment of the camera is of the usual completeness and finish for which the Kodak Company is famous. An important feature which will recommend the No. 4 Screen Focus Kodak to those workers who wish to do their best work with films is the

The Screen Focus Kodak as a glass-plate camera -without the roll holder

able extension bed. This allows the operator to work to within in. of the subject when focussing the image on the ground glass—ensuring perfect accuracy and sharpness.

A rising, falling and sliding front, which adds so much to the usefulness of a camera, is provided. The rising and falling front is operated by an automatically locking rack and pinion, and the sliding front by means of runners and a simple clamping lever. The lens is a rapid rectilinear of excellent quality fitted with iris diaphragm. The shutter is the Kodak "Automatic," with pneumatic and trigger release, giving instantaneous exposures graduated from 1/100th to 1 second and time and bulb exposures. The finder is of

the brilliant description, easily opened for the cleaning of the mirror and lens, and a spirit level is attached, the two reversing together for horizontal or vertical pictures. Focussing may also be effected by means of an indicator and scale marked in feet and metres.

The new Screen Focus Kodak is described in complete detail in the very useful manual of instruction which accompanies the instrument, and in which will be found full directions for developing and printing. The price of the camera is six guineas, which, considering its advantages, cannot be considered a high figure.

The Pocket Poco Cameras. Sold by Messrs. John J. Griffin and Sons, Ltd., 20-26, Sardinia Street, Lincoln's Inn Fields, London, W.C.

This series of handy and efficient little cameras, which Messrs. Griffin are issuing this year, well sustain their claim to be considered "pocket" cameras. There are four patterns, varying in price from

The Pocket Poco A (open).

£1 1s. to £4 4s., making them suitable for all purses. Now that the inexpensive enlarger is so popular, the tendency is all in favour of such folding cameras producing quarter-plate or 5 by 4 size negatives.

The Pocket Poco A, illustrated above, is a compact little instrument measuring only 5½ by 4 by 1½ when closed. It takes quarter-plates in neat single metal slides, and the bellows have a draw of 5½ in. The body of camera is covered with seal grain leather, and the metal parts are nickel and black. The camera has a self-setting shutter for time, instantaneous, and bulb exposures. The lens is a single achromatic of good covering power, and a reversible viewfinder and two tripod sockets are included.

Pocket Poco B is of the baseboard and draw-out bellows type, and is a well-equipped camera for all-round work. The camera is well and strongly made in mahogany, leather-covered, and with leather bellows. Its dimensions, closed, are 5½ by 3½ by 2, and it fits readily into a coat pocket. It takes plates 3½ by 4½, and has a bellows-draw of 5½ in. The front is sliding, and there is a spring in the back which may be opened, disclosing the ground glass for focussing. R.R. lens, "Gem" automatic shutter, and reversible brilliant finder are included. It is also made in 5 by 4 size. Pocket Poco C is another model of the series, and is characterised by further additions to the equipment than is included in the two patterns previously mentioned. It has a rack and pinion focussing attachment and a bellows-draw of 7½ in. It is well made in dovetailed mahogany, with strong piano hinge to baseboard. The metal parts are highly finished nickel and brass. A focussing panel and ground glass form part of the back, and the lens is a good rapid rectilinear, Automatic shutter, brilliant finder, tripod sockets, etc., are included. This little instrument is not only an efficient plate pocket camera, but the Premo film pack can also be used in the place of the double dark slide.

Pocket Poco D is the latest of the Poco series, and is very complete in all respects, both as a hand and stand camera. It is beautifully made in mahogany, and the baseboard is metal. All other metal parts, with the exception of the lens mount, are highly

nickelled. It is a very light camera, and is made in one size only, $4\frac{1}{2}$ by $3\frac{1}{4}$. Its outside measurements when closed are 5 by $3\frac{3}{4}$ by $2\frac{1}{4}$.

Focussing is by rack and pinion. The front is of metal, with rising and falling movement, and patent clamp. The back is removable, with ground glass panel. The lens is the Planatograph, and "Auto" shutter, brilliant reversible finder, tripod socket, and plate

The Pocket Poco D (open).

holder are included in the outfit, which is remarkably good value for the price, £4 4s. With this camera is furnished, without extra charge, a film pack adapter, for accommodating the Premo film pack, thus rendering it very complete for cut films as well as plates.

A NEW light, with features which invite inquiries from photographers contemplating the installation of an artificial illuminant, is now being introduced as the "F.P. Airlight Lighting System." "F.P.," in the language of the company's circular, stands for "fire-proof" and "fool-proof," and the one great claim made on behalf of the airlight, apart from power and economy, is safety in inexperienced hands. The active principle of the light is gasolene vapour mixed with air, which is consumed in a Bunsen burner, and raises to incandescence a mantle very similar to that used with coal-gas incandescent burners. The plant generating this combustible vapour is perfectly self-contained, and—for a battery of six lights, each, so it is claimed, of 500 candle-power—occupies a space of about 4 by 1 by 1 ft. No gas connection or other auxiliary is required—a gasolene burner vapourises the main supply of that material, and the apparatus, as we have examined it, works silently and without odour. The light resembles acetylene in its quality more than other illuminants, and we are informed that it has been found satisfactory for distinguishing between minute differences of colour such as blacks and blue-blacks. The present promoters, The British American Safety Airlight Co., of 66, Victoria Street, Westminster, put up the light in various forms, the most suitable for photographic portraiture being presumably the "double arc," designed to give 1,000 candle-power. As the light can be installed anywhere, as it consumes only light spirit such as can be bought at any motor garage, and as the cost of running it is evidently very low, there seems good reason for directing attention to it. The types of lamp now made are probably not well suited for studio lighting, but the production of others, meeting photographers' requirements, should not be a difficult matter.

A NEW price-list reaches us from Ilford, Limited, which specifies the many sizes in which the Ilford products are made, and gives a series of brief notes on the special suitability of the various Ilford plates and papers. The proportionate speed of plates, etc., in seconds' exposure required is among the notes, and will probably be useful to many:—Ordinary and Chromatic, 1; Empress, $\frac{1}{2}$; Rapid Isochrom, $\frac{1}{2}$; Special Rapid, $\frac{1}{4}$; Zenith, $\frac{1}{4}$; Monarch, 1-9; Process, 8; Half-Tone, $1\frac{1}{2}$; Special Lantern, 50; Rapid Bromide Paper, 5; Slow Bromide Paper, 20.

RECEIVED.—"Salon" plates. The Gem Dry Plate Company, Limited, Willesden Green, London, N.W. A new ultra-rapid plate on which we shall report in due course.

New Books.

"The Camera in the Fields, a Practical Guide to Nature Photography." By F. C. Snell. London: T. Fisher Unwin. 5s.

More Nature and the camera! And Mr. Snell gives us a good deal of both. His plan of instruction is extremely simple and extremely pleasant. He spends a couple of chapters in telling us about apparatus and the best kind of fit-up for the work—in the course of which he recommends an "exposure metre"—and then out he goes into the country and begins to talk about birds, and beasts, and reptiles, and the various little things he has observed about them and endless photographic ways and means which have suggested themselves to him. In all this there is as much to be learnt of natural history as there is of photography, and that is the beauty of the book; it is not for naturalists, but for photographers who would find new interests and occupations. Hence Mr. Snell's useful hints on the manners and customs of his humble friends are not superfluous. Thus, beware of the badger, for he is vicious and savage by nature, and will claw you if he can get the chance. And when pursuing the slow-worm do not make him angry or, in the excitement of the moment, he will break off his tail, and you will be chagrined to see the two halves of him departing in opposite directions.

Mr. Snell chats in this wise while he takes us into his confidence in the matter of photographic methods. And as his very elegantly printed book contains a hundred or so of examples of the author's work, we do not hesitate to name it as a guide and incentive to the branch of photography which, we are glad to say, is finding new adherents every day.

"German Technical Words and Phrases." An English-German and German-English Dictionary. By C. A. Thimm and W. Voß Knoblauch. London, E. Marlborough and Co., 2s. 6d.

The arrangement of this pocket dictionary is one that can be desired as it collects the technical and "shop" terms of various crafts under the appropriate generic heading. But some of the synonyms strike us as awkward, to say the least of it. Thus under "Photography" to translate "Prints" and "Printing" as "Abdrücke" and "Vervielfältigung," or "Drucken," is to mislead the reader of German photographic books where "Copieren" and "Copiren" are used for these terms almost without exception, and "Brennweite" is used a hundred times to "Fokus" once. These, however, are exceptions: usually the terms, are the natural ones.

"Das Pigment Verfahren." By H. W. Vogel and Paul Hanneke. Published by Gustav Schmidt, Berlin. Price 3 marks.

This is the fifth edition of the late Dr. Vogel's handbook on the carbon process, revised by Herr Hanneke, and contains complete directions not only for the preparation of the tissue, but also for its application to ordinary work, and special supports, and also for photogravure. The gum bichromate and ozotype processes are also treated of, and the fact that a fifth edition is called for proves that it is generally accepted in Germany as a reliable and useful text-book.

In view of the danger from fire, the Theatres and Music Hall Committee have recommended the London County Council to prohibit the cinematograph at Sunday concerts in licensed places.

THE Council of the Scottish Photographic Federation, at a meeting held in Stirling, resolved that the Federation outing be to Blairgowrie on Saturday, June 3. Last year's outing to Callander was a decided success, and this year's must be even a greater success, Blairgowrie being the cradle of the Federation's institution, with a large membership in the immediate vicinity.

ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held April 11; Major-General Waterhouse in the chair. A paper on "Three-Colour Photography," by Dr. G. Aarland, of Leipzig, was read by the secretary. The author treated, in a general way, of filters, sensitisers, and inks for three-colour work, and urged that currently accepted views must be modified. He claimed stability for many of the aniline colours capable of employment in inks, and urged that varnish should not be regarded as a necessary vehicle for them in inks, suggesting, apparently, that inks such as those used in the Rembrandt intaglio process might be employed. The Joly process was at present the subject of investigation by the author, with a view to securing finer rulings of the triple-coloured line-filters. In regard to sensitisers, a new dye, "Collochrom," the invention of a Leipzig chemist, was stated to be an advance on Homocool, Pinachrom, and methyl red, which were spoken of highly as sensitisers for panchromatic effect. One drawback of the isocyanine sensitisers was that, as they imparted increased sensitiveness to red, the green-sensitiveness fell. "Collochrom," it was stated, gave greater sensitiveness to red, with little or none to green. Reference was also made to the method of the Bayer Co. of dyeing silver bromide, and afterwards emulsifying it. In the making of half-tone three-colour blocks, the author ascribed the large share which the fine-etcher now has in the final result, and drew attention to the Schultz method of etching as aiding in the elimination of hand-work. Of printing inks, he found the best were those of Fleming and Co., and Ault and Wiborg. Mr. Arthur Payne criticised the paper as somewhat vague, and stated his view that the "ideal" inks, as that term is commonly employed in three-colour work, are not the actual complementaries of the colour sensations.

A paper, by Mr. Alfred Watkins, on "Calculating Exposures in Pinhole Photography" was also read. The author referred to the variation of the best size of pinhole for various focal distances, and stated Abney's rule for the diameter as $\cdot008 \sqrt{b}$, where b is the focal

length. The pinhole, however, could depart considerably from the diameter given by this rule without affecting the results. For calculating, by meters, or otherwise, exposures with pinholes, the author now adopts a system which is a development of the rule first published in "The British Journal Almanac" for 1893, viz., divide the aperture by the distance from pinhole to plate (as in finding f numbers), and using the quotient as the f number, calculate exposure with an f number one tenth of this, and give 100 times the exposure. This calculation Mr. Watkins, taking a suggestion from Dr. D'Arcy Power, has now reduced to the following simple shape. He gives to each pinhole a number such that when multiplied by the extension the product is used as the f number in calculations, the result, as found in seconds, being taken as minutes.

The secretary showed a simple device for measuring the diameter of a pinhole. A graduated rule was fixed at a small angle to a metal straight edge so that the side of the narrow triangle opposite the angle between the two was a known fraction of the length of the rule. Thus the diameter of the needle will be indicated by the point at which the needle stops on being pushed between the two edges. For example, if the rule is 4 inches, and the separation from the one end of the straight edge is 1-16, the needle, if it stops at the 2 inch mark, will have a diameter of 2-4 of 1-16, or 1-32nd of an inch. The secretary also exhibited a centre punch, as used by Mr. Bolas, for making a pinhole which shall be an aperture only, not a tunnel, in a metal plate.

WOODFORD PHOTOGRAPHIC SOCIETY.—Mr. J. C. S. Mummery gave an instructive demonstration on "Gum Bichromate Printing" before the members of this society on Thursday last. Mr. Mummery gave a lucid exposition of his methods. He showed his audience the papers most suitable for the process. For large prints he used a rough surfaced drawing paper, while for finer or smaller work "Autotype single transfer paper." For coating Mr. Mummery recommended 4 oz. gum dissolved in 8 oz. water for the gum solution. For the pigment he recommended 45 gr. ivory black and 9 gr. burnt sienna, and for coating this pigment should be incorporated with one ounce of gum and one ounce of saturated solution bichromate of potash. Several pieces of previously exposed prepared paper were then developed. Mr. Mummery did this by wetting them, laying them on a glass easel, and spraying with a very fine spray of water, the unexposed portions of the picture being gradually and evenly washed away.

BACUP PHOTOGRAPHIC SOCIETY.—The annual meeting of this society was held on Monday evening last, in the new premises, at the Bacup Mechanics' Institution. The secretary, Mr. W. J. Sutcliffe, read his report, which gave evidence of a satisfactory year's work.

EDINBURGH PHOTOGRAPHIC SOCIETY.—At the last meeting of this society Mr. James Paton's lecture on "Frans Hals" was read by Mr. Thomas Rennie. Frans Hals was described as the first great artist of Holland, and, amid all the exploiters of new fields, he is to be named only after the giant Rembrandt. No man was more strictly and exclusively a portrait painter; no work of his is known in which the interest does not centre alone in the human countenance and form. Of peculiar interest to the photographer also is his accomplishment from the fact that he was the first to solve the vexatious problems of pictorial grouping. And we might almost be constrained to believe that Hals in his practice realised the secret of instantaneous photography. In some of his pictures the figures are not only vital and instinct with feeling, the very action is seen in process even under the most distracting and difficult conditions, on a great oblong canvas, in the full blaze of light, with every individual demanding his fair share of prominence and realisation. Without the unifying and harmonising witchery of chiaroscuro, Hals yet produces a pictorial unity. In our own day he has been re-discovered, and although commercial

value is ever a poor criterion of art, it is certain that the works of Hals are now more justly estimated than they have been at any time since the hey-day of his prosperity.

BOWES PARK AND DISTRICT PHOTOGRAPHIC SOCIETY.—On Monday, April 3, Mr. H. W. Bennett, F.R.P.S., gave a lecture, before a large audience, on "Carbon Printing," at the society's headquarters, Unity Hall, Wood Green. Mr. Bennett explained the theory of a carbon print, and then gave a practical demonstration by developing several prints. He then brought before the members' notice the advantage of his improved sensitising bath, whereby a worker can keep by him a stock of various coloured tissues and sensitise for himself as occasion arises. This is essentially a method which should appeal to small workers, as it obviates the necessity of keeping a large stock of sensitive material. By using this particular bath one can obtain all the gradation of tissue which is sensitised in the course of manufacture, and one great advantage is that gas fumes do not affect the tissue during drying operations. The formula recommended is: Potassium bichromate, 4 dr.; citric acid, 1 dr.; water, 25 ozs.; ammonia, .880, about 3 drs. This bath keeps for some months, and may be used repeatedly. To sensitise, use the bath as cold as possible and immerse the tissue for one minute and a half.

CROYDON CAMERA CLUB.—An interesting and practical demonstration, on "Home-made Lantern Plates," was given before the members of this club on Wednesday of last week by Mr. S. H. Wratten. A condensed report of Mr. Wratten's paper appears on another page.

GATESHEAD CAMERA CLUB.—The lantern slides entered in the exhibition in connection with this club for prizes offered by Messrs. Hurman, of Newcastle, were judged by Mr. Wm. Parry, of North Shields, the awards being as follows:—J. T. Brownlow, silver medal; S. Thompson, a guinea camera; T. W. Nicholson, photographic goods to the value of half-a-guinea. A bronze medal offered for competition by Mr. T. W. Nicholson, was awarded to S. Thompson.

YORKSHIRE PHOTOGRAPHIC UNION.—The annual meeting of the Yorkshire Photographic Union was held on Saturday last at the Bradford Grammar School. An exhibition of work by members of the Bradford and Leeds societies was on view during the afternoon, together with an interesting collection of the work of the late H. P. Robinson. The meeting was held under the presidency of Mr. Godfrey Bingley, and there was a large attendance of representatives of societies from all parts of Yorkshire. The Chairman, in opening the proceedings, referred to the success which had attended the work of the Union during its six years of existence. The hon. treasurer (Mr. Alex. Keighley) presented his accounts, which showed a balance to the credit of £16 14s. 8d., and Mr. E. Clough, the hon. secretary, presented his report, which showed the steady advance of the work of the Union. During last winter the Union provided no fewer than 175 lectures for the various photographic societies in the county. It was announced that the ballot for the election of officers had resulted as follows:—President, Mr. Godfrey Bingley (Leeds); vice-presidents, Mr. C. B. Howdill (Leeds), Mr. P. Lund (Bradford), Mr. Percy Sheard (Leeds), Lieutenant-Colonel Johnson (Hull), and Mr. J. Cook (Huddersfield); hon. secretary, Mr. A. Keighley (Keighley); hon. secretary of the portfolio section, Mr. W. H. Atkinson; hon. secretary of the lantern-slide section, Mr. W. H. Houghton; hon. business secretary, Mr. E. Clough (Bradford). The following had been elected as the official judges for the year 1904-5:—Messrs. G. Bingley, A. Keighley, P. Sheard, Gilbert Foster, R.B.A., Percy Lund, and Harry Wanless.

SOUTHPORT PHOTOGRAPHIC SOCIETY.—An exhibition of slides in connection with the members' lantern slide competition was given on Thursday evening of last week at the Queen's Hall, Southport, by Mr. G. Cross, hon. secretary. Twenty-one sets of slides were sent

in by fifteen competitors, and the society's bronze medal for the best set of six was awarded to Mr. T. W. Banks. A medal, presented by Mr. A. Barnett, for the best slide sent in, was awarded Mr. W. Williamson.

GLOUCESTERSHIRE PHOTOGRAPHIC SOCIETY.—The annual business meeting took place on Monday evening last, when the following officers were elected for the ensuing year:—President, Mr. Sheffield Blakeway; vice-president, Mr. J. Tibbitts; joint hon. secretary and treasurer, Mr. Edward A. Ind, 36, Northgate Street, and Mr. S. A. Pitcher, College Court; hon. lanternist, Mr. A. H. Pitcher; committee, Messrs. Dugdale, Wells, Hatton, Gransmore, Jaynes, and Dr. Clark.

DARWEN PHOTOGRAPHIC ASSOCIATION.—On Thursday evening of last week Mr. Walter D. Welford, representing Messrs. Burroughs, Welford, and Co., lectured before this association upon "Little Things and Pictorial Photography."

News and Notes.

At the annual meeting of the Yorkshire Photographic Union on Saturday last Mr. Percy Lund gave an address "On Making Use of Photography." He said that photographs nowadays must be really interesting from one point of view or another, or they would not command a moment's attention. The making of photographs was taken up as a hobby, but amateur photographers might just as well turn it to profit in some way or other. He did not mean financial profit, but it might and ought to be used to bring to the photographer culture of some kind. In default of other definite work Mr. Lund suggested to the amateur photographer that he should collaborate with the student of some subject, whose work he might advance at the same time that he himself gained an insight into that study. As an example of the work which might be done, he instanced Mr. Godfrey Bingley's most valuable geological photographs, and he mentioned that he had been himself studying the ancient monuments, the dolmens, menhirs, and colossal erections which existed in almost every part of the world. If he was not able to use his camera with facility, he would certainly have had to call in the aid of another photographer to make the study of those works possible.

Old members of the Photographic Club will regret to learn of the death of Mr. F. H. Carter, which took place on Saturday, the 8th inst., at Hornsey, N. He had been suffering from a painful illness for some years. Mr. Carter was among the earliest of photographers to practise the gelatine process, and for many years was a constant attendant at both the meetings and outings of the club, and was also for some years a familiar figure at the Convention meetings.

New South Wales Photographic Employees' Association.—The first annual meeting of this Association was held on February 22, 1905, the vice-president (Mr. N. Bradley) occupying the chair. The secretary reported that the past year had been most successful, as the Association started with fifteen members, and had increased to nearly a hundred, and the financial statement showed a very good balance in hand. The election of officers resulted as follows:—President, Mr. J. C. Cruden; vice-president, Mr. H. Bradley; secretary, Mr. Walter Davies; assistant secretary, Mr. J. Stuart, jun.; treasurer, Mr. A. Morrison.

Royal Institution.—The following are the lecture arrangements at the Royal Institution, after Easter:—Professor L. C. Miall, Fulleren Professor of Physiology, R.I., Three Lectures on the Study of Extinct Animals; the Rev. H. G. Woods (Master of the Temple),

Three Lectures on Velazquez; Professor Sir James Dewar, Fullerton Professor of Chemistry, R.I., Three Lectures on Flame; Professor A. Fleming, Three Lectures on Electromagnetic Waves (The Tynall Lectures); Professor H. Marshall Ward, Two Lectures on Moulds and Mouldiness; Dr. J. G. Frazer, Two Lectures on The Evolution of the Kingship in Early Society; and Mr. A. H. Savage and Mr. A. H. Savage, Two Lectures on Exploration in the Philippines. The Friday Evening Meetings will be resumed on May 5, when a Discourse will be delivered by Professor H. E. Armstrong on Problems underlying Nutrition. Succeeding Discourses will probably be given by Professor E. Fox Nicholls, Sir Charles Eliot, K.C.M.G., Professor W. Bruhl, Mr. George Henschel, and Sir William H. White.

A NEW Warwick Competition.—Particulars are to hand from the Warwick Dry Plate Company of a series of cash prize competitions for 1905, for photographs taken on Warwick Plates. Each competitor must be a member of some photographic society or club in the United Kingdom, and entry forms and conditions will be obtainable either from the Warwick Dry Plate Company, Warwick, or from the Secretary of the society or club. Twenty-two pounds ten shillings will be given away monthly during May, June, July, August, September, and October, as follows:—1st prize, £10, together with a donation of £5 to the photographic club to which the winner belongs. 2nd prize, £5, together with a donation of £2 10s. to the photographic club to which the winner belongs. Should the winner of either prize belong to more than one club, he shall name the club he wishes the donation to be given to. A further donation of £10 will be given at the end of the season to the club which has supplied the largest number of competitors during the season.

AMERICAN Federation of Photographic Societies.—At the annual meeting, held March 22, 1905, at the Metropolitan Camera Club of New York, the following clubs were represented:—Pictorial Club of Philadelphia; Capital Camera Club of Washington, D.C.; Boston Camera Club; Columbia Photographic Society of Philadelphia; Photographic Section, Pittsburg Academy of Science and Art; Wyoming Valley Camera Club of Wilkes-Barre, Pa.; Salon Club of America; Toronto Camera Club; Brooklyn Camera Club; Metropolitan Camera Club; nineteen delegates being present. The Franklin Institute of Pennsylvania was appointed temporary custodian of the Historical Records, pending arrangements with the Congressional Library at Washington, D.C. Resignation of the Secretary was accepted, and Mr. William T. Knox, of Brooklyn, was elected secretary for the unexpired term. Permanent foreign representatives of the Federation were appointed as follows:—Great Britain, H. Snowden Ward; France, A. H. Stoiber; Austria, Mathies Surin; Belgium, Victor Stouffs; Italy, Alfredo Ornano; Denmark, Copenhagen Photo. Klub; Germany, Otto Scharf; Australia, A. G. Griffiths; India, Photographic Society of India. For the Second American Salon it was decided to appoint local advisory juries in each section of the United States (the representatives abroad arranged for similar preliminary juries). All entries to be sent to representative in each district. A certain percentage of work to be forwarded to the Metropolitan Camera Club by the representative, and balance returned to senders, who thereafter have the privilege of sending direct to the New York headquarters, if they so elect. A national preliminary jury, composed of the foremost American pictorial photographers, will then select all entries that are up to the standard, and submit them to the jury of Painters for the final selection. The closing date for entries (at New York) to be November 1905, and no entries will be received thereafter. It was resolved that no photograph which was entered for the First American Salon be eligible at the Second, or succeeding Salons, as it is desired that American Salon shall be composed of work not heretofore shown, and represent the accomplishment of the current year.

EDINBURGH PHOTOGRAPHIC CLUB AND THE SCOTTISH PHOTOGRAPHIC FEDERATION.

To the Editors.

Gentlemen,—But for the possibility of some of your readers being misled by the letter of "An Associate of the S.P.F.," contained in your issue of 7th inst., I would not reply to his letter, for I do not care to accord the satisfaction of a gentleman to an individual who has not the pluck—always the mark of a gentleman—to put his name to his letter.

The reason why "the Club" rescinded its resolution to join the "Federation," as stated in the letter of its Hon. Secretary to me intimating the fact, was "in the interests of the continuity of the Club." This decision was arrived at in the course of a debate on a motion to dissolve "the Club" on account of its having joined the "Federation."

Your anonymous correspondent more than hints that my statements are misleading. On Wednesday, 5th inst., the champions of the Scottish Photographic Federation had an opportunity of placing "the facts as generally current in Scotland" before a meeting of the Edinburgh Photographic Society in support of a motion that that Society should join the "Federation"; but their opponents had also the opportunity of replying, with the result that while 15 votes were cast in support of the motion to join, 76 were given in support of the amendment that the Society do *not* join the "Federation." I leave your readers to judge of the merits of "the facts."

In my letter to you, Sirs, I distinctly state that the membership of "the Club" is limited to forty, all of whom "must be" members of the Edinburgh Photographic Society, and point out that owing to the similarity of the names "the Club" and the Society are apt to be confused, but that the former in no sense represents the latter. Your printer has changed the words "must be" into "probable," and that may have confused your anonymous correspondent, but I certainly have no desire to disparage "the Club," and fail to see wherein I have done so.

The best reply I can make to your correspondent's last query is to quote a sentence from the letter of the Hon. Secretary of "the Club" intimating the rescinding of the resolution to join the "Federation." He says:—"I beg to inform you that the Edinburgh Photographic Club have decided, solely in the interests of the continuity of the Club, to rescind their resolution to join the Scottish Photographic Federation."

With apologies for taking up so much of your valuable space,
—I am, yours faithfully,

J. S. McCulloch,

Hon. Sec. Edinburgh Photographic Society.

3A, North Street, David Street, Edinburgh.

April 8, 1905.

[In justice to "An Associate of the S.P.F.," we may state that our correspondent wrote, too late for last week's issue, asking us to delete the concluding query contained in his letter.—Eds., B.J.P.]

THE P.P.A. ASSISTANTS' CERTIFICATES.

To the Editors.

Gentlemen,—Please allow me to challenge your statement that in your last week's issue, page 243, re "Situations Open to Assistants." For wages of the unskilled labourer you may find a situation, but ask a bricklayer's wages—that is, £2 2s. per week—and you will

not find a berth without a protector; that is, an interested person in a going concern. You can find that out yourself. Advertise in your own journal under chiffre; offer your ability, and transform yourself for once in a sort of secretary for your Editor, à la "Answers," and then report—that shall be the article of the year.

I judge from the going trade in this town of 150,000 inhabitants. There are almost fifty established photographers here, only one has a paying concern—and the proprietor is a photographer.—Kindly excuse yours,
COMPULSORY RETIRER.

[We print our correspondent's letter as exactly as its caligraphical and orthographical mannerisms permit, but he will pardon us, we hope, if we describe it as incoherent. We should be sorry to class the writer with the general body of assistants.—Eds., B.J.P.]

To the Editors.

Gentlemen,—On behalf of the Committee of the Professional Photographers' Association, I thank your correspondent "Scot" for the first practical criticism we have had on the certificates scheme from the assistants' side of the question. If the point raised had been submitted to us during the period between the publication of the draft scheme and of issuing the complete prospectus, I am certain we should have recognised its importance and have provided for the cases he refers to. As it was, we had to submit to the mortification of having our endeavours to benefit both employers and employees received with that appalling silence which is worse than direct condemnation.

We shall not be able to alter our conditions until the year's probation has expired; but I may say that as far as fees are concerned it is not the idea of the Committee to make money out of their project. I cannot, of course, say what the Committee will or will not think proper to do, but, judging by the general policy they have adopted, I should say that no one need fear being disadvantaged pecuniarily or otherwise by taking a certificate under the present conditions. Probably, when the fees are reconsidered, what will happen is that, say an assistant takes out a third-grade certificate, he will pay the minimum fee of 10s.; on taking out a second grade he will be liable to pay, not the entire fee for second grade, but the difference between the fees for third and second grade—that is, another 10s., and so on.

In our friend "Scot's" case, he admits most sensibly that he cannot claim a training attainable only, to use your editorial words, "in a hundred or so studios," but it cannot be a disadvantage to him to have passed a test which at least proclaims him an efficient photographer. Under any circumstances, his business abilities as a manager would not be a matter under our cognisance. Those would be taken to be included in the expression personal character, with which we have nothing to do.

In conclusion, may I emphasise the fact that assistants have no reason to look upon the Association as a body inimical to their interests. The Committee recognise that many of the assistants of to-day will be the professional photographers of to-morrow. We cannot interfere between masters and servants in individual cases, but we wish generally to establish more cordial relations between the two classes. As representatives of the masters, we admit fully the interdependence. Photographers cannot conduct their businesses without assistance, and the more highly trained assistants are as a class the more independent they will become, and the less liable to the competition of what is practically unskilled labour.—I am, etc.,

WILLIAM GROVE, Hon. Secretary.

51, Baker Street, W.

April 10, 1905.

To the Editors.

Gentlemen,—In reference to the remarks of "Scot" last week in the B.J., it seems to me that the P.P.A. would clear the subject of the certificates considerably if they could give specifications, as it were, of the qualifications of assistants who can, and cannot, expect to obtain the first, second, or third grade certificate. As it is, we have the list of questions drawn up by the P.P.A., but we should like to know what proportion of the qualifications the candidate must possess to be granted the certificate. In other words, Sirs, let the P.P.A. dissect one or two certificated assistants, and let us see the manner of men they are.—Yours truly,
J. PATTERSON.
Glasgow.

To the Editors.

Gentlemen,—We hear the views of assistants like "Scot" and myself, but what about the employers? Are we to understand that preference is likely to be given to holders of the certificates by employers generally? The P.P.A. includes only some hundred or two members. What about the great majority outside? Will they recognise the P.P.A. diploma, or what steps are being taken to lead them to do so? I should like to hear the views of non-members of the P.P.A.—Yours faithfully,
"POUND A WEEK."

AMERICAN COPYRIGHTS.

To the Editors.

Gentlemen,—I am desired by my Committee to write you in reference to paragraph commencing "Copyright Query" under "Answers to Correspondents," on page 260 in your issue of 31st ult.

Although this might be legally correct if the picture is not already registered here by a British subject residing in America, my Committee are of opinion no one should be advised or encouraged to do this, which is morally, if not legally, a piracy, especially when we are trying to get this recognised by publishers on both sides of the Atlantic.

My Committee know a photographer, long resident in New York, who is still a British subject, and who is constantly sending photographs to this country for registration and reproduction.

Therefore my Committee felt it might place your correspondent or others in a dangerous position, hence the reason for this letter, which I hope you may find space for in the next issue of the JOURNAL.—I am, dear Sirs, yours faithfully,
HENRY GOWER, Secretary.

23, Soho Square, London, W.

April 10, 1905.

PHOTOGRAPHERS' ADVERTISEMENTS.

To the Editors.

Gentlemen,—I have carefully followed up the columns of "Advertising and the Professional Photographer," by Mr. W. J. Casey in THE BRITISH JOURNAL OF PHOTOGRAPHY of March 24, 31, and April 7. There are certainly very good hints given to photographers who wish to advertise, and no doubt it will be a good lesson to every photographer who does advertise his business. I shall esteem it a favour if you will kindly advise me in my case how to advertise, and must therefore give you a short description of my studio, situation, etc., etc. A few months ago I took over this place (which unfortunately I found in a very bad and neglected state). I closed same for about a month or so to make necessary alterations, putting up notices in the windows—"These premises will shortly be re-opened as..... by....." When I re-opened it, with nice and attractive show windows, soon after, I circulated pamphlets round the neighbourhood (between 15,000 and 18,000), one of which I herewith enclose,

and I also advertise in one of the best local papers. The neighbourhood consists of a good middle-class people. In what way would you now advise me to advertise? I find pamphlets rather too expensive.—Yours faithfully,

L. C. T.

[Our correspondent asks for advice of a kind which is not easily given by anyone not on the spot, but if we may criticise his price list, we think it says too much and shows too little. It confuses the reader with too many specialties. It would have been much better to have filled nearly all the eight pages of art paper at disposal with half-tone reproductions of pleasing portraiture, explaining in a word or two under each what distinctive styles they represent. A smaller list, suitably illustrated, would have been more efficient as a business bringer, it seems to us: or even a postcard well done in half-tone. There are several firms who make a specialty of such stationery for photographers. We shall be glad to find space for advertising suggestions from our readers, and we will answer queries on this subject in each week's "Answers."—Eds., B.J.P.]

BREATHLESS PHOTOGRAPHY.

To the Editors.

Gentlemen,—With reference to your paragraph in last week's issue on above subject, a slight error has crept in regarding the pictures of the Grand National being shown at the Palace Theatre. This is the work of the Autoscope Company, and not that of the Company you mention. It is the outcome of having five cameras on the course.

You hit the right nail on the head in saying that very few people, even photographers, have any idea of the "breathless" haste with which we work on "topical" events. The Boat Race we did for the Palace Theatre was the work of three cameras—one at the start, one at the waterworks, and one on a launch at the finish. Each operator made for the dark-room as quickly as he could after exposing. The one who took the finish was not able to reach Waterloo from Mortlake Station until 1.20 p.m., yet the complete film was exhibited at the matinee the same afternoon at the Palace. Surely marvellous enough.

To give some slight idea of the work that has to be put into film, there were, roughly, 6,500 distinct photographs in the Boat Race picture. When printing the positive film, which is projected on the screen, each of the 6,500 pictures in the negative receives separate exposure to make the transparency.

We do not know other firms' methods, but the secret, if it can be called a secret, of our speed is division of labour. Only by cutting the negative into several sections, and having several printers at work, are we able to produce prints in such an incredibly short time.

Thanking you in anticipation of your kind correction,—Yours very truly,
For the Autoscope Company,
50, Gray's Inn Road, Holborn, W.C. WILL. G. BARKER.
April 10, 1905.

At the exhibition of the Röntgen Society, opened on Thursday in last week, improvements of apparatus tending to economy of space and power were on show. Among the new inventions were several X-ray tubes permitting the use of alternating current direct from the mains. Hitherto only continuous current, often necessitating costly and cumbersome apparatus, had been obtainable. Messrs. Watson had a specially interesting stand, on which were displayed lead-glass spectacles and opaque rubber gauntlets, giving perfect immunity to operators. The lead glass is perfectly transparent to the human gaze, but does not permit the passage of X-rays.

Answers to Correspondents.

- * All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.
- * Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- * Communications relating to Advertisements and general business affairs should be addressed to MESSES. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.
- * For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington-street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

- B. T. Cornforth, 5, Rock Street, Higher Broughton, Manchester. Photograph of the Bolton Town Hall, Coronation Illumination, 1902.
- R. Hodgson, 93, Pinestone Street, Sheffield. Photograph (Combination) containing Four Views, with Fancy Border on the Postcard, with Coat of Arms.
- A. J. Ashbolt, 52, Oxford Avenue, Southampton. Two Photographs, Groups of Canon Stephenson, Rev. B. J. Deane and Rev. F. H. Sangster. Two Photograph of the Rev. Canon John Stephenson.

"ESSEX" AND OTHERS.—In our next.

WALTER SWINTON.—8, King Street, St. James', S.W.

E. WEST.—1. The design is very good. We would suggest, however, as the studio is of a good width, that the solid at either end be increased to 5 ft. or 5 ft. 6 in. Also that the glass, at the side, be brought 6 in. or 8 in. nearer to the floor. 2. For the roof, we should recommend either light green or medium-blue blinds, and for the side, curtains of "art serge" of similar tint. 3. Any light, quiet colour, French grey, for example.

J. E. LINCOLN REES.—We do not know a firm which makes a speciality of the article. Try Fairbanks, Lavender, and Son, Eldon Works, Walsall.

GLAZING PRINTS, ETC.—1. I have a large number of prints to glaze, something like 8,000 half-plates per day. Could you give me an outline of what you would advise to get these dry quickly after squeegeeing down. A colleague of mine suggests that I should build cupboards against the walls, with openings at the bottom to admit the air from outside, and have lighted gas jets at the top, so as to cause a continual current of air through the cupboards. He contends that I should then have a quick and perfect drying cupboard; but I am inclined to doubt its efficacy. What is your opinion? Do you think such a cupboard would be quick drying? 2.—Can you give me a method of preparing glass for glazing bromide prints? One where there is no necessity to polish dry before laying the prints down, i.e., to clean the glass with a sponge, prepare it, and then lay the prints on, all in "wet stages," if I may so call it. 3. Can you tell me a quick way of removing surface markings and abrasions on bromide paper (glossy)? I've tried both water and methylated spirits, but neither of these are effectual in removing the deeper markings. Some of them seem indelible, and the surface of the paper very often comes away on account of the print having to be rubbed so vigorously.—TEMPUS FUGIT.

(1) Considering the amount of work to be got through, we should say that it would certainly pay to build cupboards, and, further, to put an exhaust fan at the top, and draw heated air, at about 80 to 90 deg. F., through the same. Failing this, it would certainly be advisable to adopt the plan suggested, with the addition of gas jets below as well, so as to warm the air going through the cupboard, but, of course, the products of the gas consumption must not be allowed to enter the drying chamber. Suitably arranged, there should be no difficulty in drying the prints in an hour. If we had a plan of the room

to scale, we could possibly suggest a special cupboard. (2) There is not, so far as we are aware, any "all wet" method, but the quickest method we know is to rub the glass all over with tripoli, 1 oz.; liq. ammonia, fort. .880, 1 oz.; methylated spirit, 19 oz.; using a sponge or wash leather, and then polish off with a dry wash leather. If half a dozen slabs are treated like this, the first will be dry enough to polish by the time the last is treated with above. Immerse the prints in methylated spirit, and then squeegee down. They rapidly dry this way. (3) Stubborn stains can be removed by rubbing with a very weak solution of potassium cyanide in a mixture of water and methylated spirit; this must be carefully used, or the image will be attacked.

PORTRAITURE IN COLOURS.—Could you kindly inform me if there is any firm that is making portraiture in natural colours a specialty? I should like to practise this branch of photography exclusively; in fact, I have gone as far as possible in educating myself in this respect, and should like to know of a firm that would employ me.—**MARTREES.**

So far as we are aware, no firm makes a specialty of this branch of photography. If our correspondent has made any substantial progress he should have no difficulty in obtaining a situation with one of the leading West-end London houses.

J. HARRIS.—Use the following: (1) Barium chloride, 30 gr.; hard gelatine, 90 gr.; water, 5 oz. (2) Ammonium sulphate, 15 gr.; water, $2\frac{1}{2}$ oz. Allow the gelatine to soak in the barium solution, melt at 100 deg. Fahr. in a water bath, and add No. 2, stirring all the time; allow to set well, break up, and wash to remove the ammonium chloride, then drain, and remelt, and add slowly: Chrome alum, $7\frac{1}{2}$ gr.; water, $\frac{1}{2}$ oz.; stirring all the time; the paper may be floated on this for a minute and hung up to dry.

FAILURE.—Your chief trouble arises from immersing the cards in the salting solution. We should advise the following procedure: Arrowroot, 17 gr.; sodium chloride, 16 gr.; citric acid, 5 gr.; sodium carbonate, 11 gr.; water, 1 oz. Rub the arrowroot into a cream with a little water, add the citric acid and soda to the rest of the water, and when effervescence has ceased, add the salt, and boil; stir in slowly and gradually the arrowroot cream, and boil till a clear jelly is obtained; allow to cool, and allow 20 minims for every card, and brush over with a fairly stiff hogs'-hair brush, and work the brush till surface dry; then allow to dry naturally, and paint with: Silver nitrate, 48 gr.; distilled water, 1 oz. If you want the cards to keep, add to above citric acid, 10 gr. Allow 10 minims of this solution for every card, and apply in the same way; be careful not to use brushes bound with metal. If you prefer to float, you can do so, but the solutions must then be half the above strength. Dry the cards naturally.

F. VERNON.—You can either use Conte crayons or obtain from any dealer special bromide pencils for the purpose. The only work on the subject is Johnston's "Retouching," published by Marion and Co., Soho Square.

PHOTOGRAPHS ON IVORY.—Can you give me a formula for sensitising ivory in order that a photographic print may be made direct without the intervention of a gelatine film as in the carbon process? I believe there are methods by which photographs on woodblock can be produced direct.—**MINIATRIST.**

There is no difficulty in doing this, and we would suggest painting the surface of the ivory with: Silver nitrate, 60 gr.; alcohol, $\frac{1}{2}$ oz.; water, $\frac{1}{2}$ oz. Dissolve, and add sufficient

liquid ammonia (fort. .880) to redissolve the precipitate first formed. This will dry fairly quickly, and assuming that the ivory is flat, it could be printed under a negative and toned, preferably by brushing on a strong gold or platinum bath, and then fixed by immersion in strong hypo. If nothing but a very faint image is required for subsequent painting, then the above bath may be reduced to half the strength and the toning omitted. The methods of the wood-block printer are not so suitable as the above.

H. P.—Look through the columns of the small "Business and Premises" advertisements, or insert a small advertisement yourself. This latter course would probably lead to satisfactory results.

SENSIT.—Your best plan would be to salt the paper first with a mixture of chloride and bromide of ammonia, then sensitise with silver, and again salt so as to have excess of the chloride present, and not excess of silver. If you turn up our "ALMANACS" you would find numerous formulæ, which, omitting the gelatine or collodion, would give you the quantities.

ANILINE PROCESS.—Will you kindly give formula for sensitising liquid, i.e., proportions of bichromate, acid, etc.? In what form and proportions is the aniline used—the colourless oily fluid or which of the dyes? How is the vapour produced and applied to the sensitive print?—**G. D. S.**

The formula for the aniline process is as follows:—Potassium bichromate, 1 oz.; phosphoric acid (sp. gr. 1.24), 10 oz.; water, 10 oz. Float a hard paper, such as Steinbach, on this for one minute, and dry quickly, and expose on the same or next day. The exposure in summer sunlight is about three minutes under a tracing, and the copy appears in yellow lines on a greenish ground. To develop, the print is placed on the bottom of a shallow box, to the lid of which are pinned several sheets of blotting-paper, soaked in a mixture of aniline-oil, 1 oz.; benzole, 15 oz. More aniline accelerates development. Spread the solution evenly on the blotting-paper, and leave the print in the box to develop, the image appears after a few minutes, and the final tint is influenced by the time of development. Short development gives blue-black, long, brownish-black. When intense enough the prints are washed in water and if they turn green add a little ammonia to the water. Commercially the aniline mixture is vaporised by steam. The ordinary colourless oily aniline is used. There is no work dealing specially with this process. The best book on such reproduction processes is "Ferric and Heliographic Processes," by G. E. Brown, published by Dawbarn and Ward Price 2s.

**** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

EX CATHEDRA.

A Seasonable Business Hint. There is no question whatever as to the enormous business that is now being done in picture postcards. A question, however, arises in our minds as to whether local photographers in country places, pleasure resorts, and the like profit so much by the business as they might do, had they a little more enterprise. We ourselves receive from time to time a goodly number of these pleasing missives, and what is very notable about them is that they nearly always bear the name of one or other of the large publishing firms who make a feature of picture postcards, and not that of local photographers. We are here referring to landscapes, of course. Why should this be so? The resident photographer is better situated for securing views of this neighbourhood than is the firm that must send operators for a day or two's work in it, and have, therefore, to secure the negatives whether the conditions are the best or not. Amongst the examples we have are many that depict buildings, ancient ruins, glens, and the like, that are anything but pleasing, for the reason that they have been taken when the trees are bare of foliage, evidently with the view of showing as much of the building as possible. These pictures are more or less depressing to look at inasmuch as, being taken for the most part in winter, there are no bright high-lights and no cast shadows. Had they been taken under the aspect of Nature at the present season, with the trees just budding into foliage, the buildings, in most instances, would show just as well, while the picture would have a bright and cheerful appearance, instead of being dull and sombre: such would be much preferred by the purchasing public. Those who have pictures of the class alluded to—those

taken under wintry aspects—will do well to re-take them under bright spring conditions. But no time should now be lost in securing them, as with the present genial weather the opportunity will be of but short duration.

Postcards of the Seasons.

While on this point, it occurs to us that it might, as a matter of business, be well for local photographers to secure negatives of certain views under different seasons' conditions—say, spring, summer, autumn, and winter—and issue them in sets as Christmas and New Year cards. Just now fruit trees are coming into blossom, and orchards, such as those in the cider counties, or those in the plum districts, might well receive the attention of local photographers with a view to pictorial postcard business. It goes without saying that in this class of work backed plates are imperative for successful negatives. Many photographers sell the right to reproduce their pictures as postcards to the large publishing houses for a mere trifle, or where they have neglected to register their copyright in them they are appropriated by them without any payment. Would they not do better to publish them themselves and reap the whole of the profit of their work? Sensitised postcards are now supplied at a very small price, and the printing can be done in spare time and by artificial light, and the prints, being direct photographs, would be infinitely superior to the majority of the mechanical prints now being issued. They would be much preferred by the public, who would no doubt be pleased to pay a somewhat higher price for them. In conclusion, we may again question whether local photographers make as much out of the picture postcard business as they might do.

The Starch Mountant.

The souring and spoiling of starch paste is a phenomenon as well known as any other to the photographer, at any rate, of the older generation; there may be plenty of younger workers who have never used any paste, but one or other of the prepared compounds on the market. To them the article by Mr. J. I. Pigg, which appears on another page, will not possess the interest which it has for those who have habitually employed the home-made starch mountant. Mr. Pigg shows that starch has its special organism which gives rise to the acidity and loss of adhesiveness which render the paste useless for photographic purposes. The spores of the "paste eel" may occur anywhere, but they are pretty certain to be in the air of a room where starch paste has been allowed to "go bad." Mr. Pigg shows that they are among the most indestructible of organisms, and once a paste is infected by them its sterilisation by ordinary means is practically impossible. The moral to be drawn from the

description of the "paste-eel's" proclivities is one which we have insisted upon repeatedly, and that is to use starch paste freshly made, discarding any which may remain after each day's work.

* * *

Dr. Miethe's Colour Projection. During this last twelve months our German contemporaries have contained, at frequent intervals highly laudatory notices of the trichromatic projection of Dr. Miethe's work; it was therefore with keen expectation of seeing something far ahead of anything shown before that we visited the trade exhibition at the Portman Rooms last week, on purpose to see this particular exhibit, and we must confess that we were extremely disappointed. We certainly have seen far finer results shown by Mr. F. E. Ives, nearly ten years ago. Making all allowances for the difficulties with the current, the one thing that particularly struck us was the absence of colour. It is true that the scarlet of a somewhat ubiquitous sunshade was well rendered, but of other colours there was but little evidence. An explanation offered to us at the time, was that the filters had faded, but we think the cause of the paleness of the colours must be looked for elsewhere, and in the nature of the filters themselves, on the following grounds. Dr. Miethe states in his book "Driefarbenphotographie nach der Natur," that the filters for projection may be conveniently identical with those used for taking the negatives, and these, he says, should pass the red from λ 700— λ 600, the green from λ 600— λ 500, and the blue from λ 500— λ 400, so that he uses the whole of the spectrum. Both Ives and Sir Wm. Abney have shown us that for correct projection quite narrow spectral bands should be used, lying approximately at λ 670 in the red, λ 514 in the green, and λ 460 in the blue-violet. If the spectral bands are widened it is obvious that each colour will excite not only its own colour sensation in the retina, but also its neighbour, and the necessary result is a lightening of its hue; thus Dr. Miethe's red screen not only excites the red but a considerable proportion of green, hence the red is a whitish red, the green screen excites not only the green, but the red and blue-violet, hence it is a very pale green, and the same applies to the violet. We had no opportunity of testing the filters either spectroscopically or against a set of Mr. Ives', but we feel convinced that the latter would have given a totally different and much superior effect. We ought not to omit to mention the extremely ingenious dodge adopted by Miethe for obliterating the coloured fringes always seen with triple projection at the edge of the disc, and this was the use of a broad frame of black velvet, on which, of course, this irritating defect was not perceptible.

* * *

Photographers' Display.

With the advent of brighter weather photographers will do well to look to their display of prints, both on show tables and walls, and in the window or showcase. Specimens, which may have been looking satisfactory during the duller weather, will lack that freshness and daintiness so attractive to the prospective purchaser, and so valuable in turning the casual passer-by into a customer. In one of his books the late H. P. Robinson remarked on the tendency of the photographer to fail to notice how the familiar specimens have faded, or become soiled and discoloured. It is often an advantage to get some sympathetic but critical friend or fellow professional from a distance to offer one or two suggestions on this matter. Such a friend brings a fresh eye to the place, and sees things as they are seen by the general public. New specimens may well be mounted on new styles of mounts.

From the purely artistic point of view good plain boards of neutral tints to harmonise with the black, grey, or sepia prints are all that is necessary, but there is no doubt that some of the more varied and showy modern mounts are popular with the public generally. The American mount makers led the way in this direction but British and Continental manufacturers have risen to the occasion when shown the way, and the selection is very varied. In small businesses the modern mount may be purchased in small lots of from 100 to 250, and the name and address stamped by the photographer himself with one of the engraved steel die presses.

* * *

Factors of Success.

Is the photographic business as flourishing as some would have us believe? This question occurs to us through a conversation with a friend who, a little while ago, advertised for a first-class operator—one for the highest class of work. The replies were far beyond his expectations, and many of them were from men who had been in the leading houses of this country, and enclosed copies of excellent testimonials from them. But the significant fact about them was that a large, if not the largest, proportion of the applicants had for the last two or three years been in business for themselves, and the businesses had not proved so successful as they anticipated, hence their application for an engagement. The specimens submitted were, in most instances, quite on a par with the work turned out from the studios in which the applicants had formerly been engaged, so that the quality of the work was not the cause of their non-success in business. That may be due, possibly, to other causes, for it must not be surmised that nowadays good photography alone will make a business; it wants more than that. It requires business tact, enterprise, and a fair amount of capital to exploit the venture. It is quite conceivable that some of those referred to were lacking in some of these respects, but they are, we suspect, much the same as many others who have started photographic businesses on their own account. Be that as it may, the above tends to show that professional photography, even amongst first-rate workers, is not quite as satisfactory as might be wished.

* * *

Amateur or Professional?

The distinction between an amateur and a professional—where does the one end and the other begin—has long been a vexed question in photography. A rather amusing case that was recently tried in a provincial county court does not seem to settle the question. It was this: The plaintiff, "an amateur photographer," trading with his wife and daughters as a certain photographic company, sued the defendant for £3 for three gross of picture postcards of his house and an enlargement. The judge, looking at some of the postcards, said, "I never saw such things as these." "But I am only an amateur," replied the plaintiff. Then said the judge, "Don't you think you had better give it up altogether? You speak as though an amateur was bound to do bad work." In the end a verdict was given for the defendant. If a man with his wife and daughters trades as a photographic company and still says he is an amateur, where can the line be drawn between an amateur and a professional? Echo says, "Where?"

* * *

Industrial Alcohol.

On another page we condense the chief parts of the report published on Friday last by the committee which has had under consideration the granting of additional facilities for the use of alcohol. One common error the report contradicts, viz., as regards the employment of alcohol in Germany. It is usually asserted that German manufacturers get their pure spirit

duty free, but the sub-committee which visited Germany reports that not a single industry, except that of smokeless powders, employs pure spirit without duty, unless it is subject to a denaturing process. The recommendations of the committee are divided between the equally important questions—we write from the photographic standpoint—of quality and price, and it appears that if the Government puts them into force, the English maker will get his spirit more cheaply than the German manufacturers did when spirit was phenomenally low in price. The present “ordinary” spirit is to have its content of wood spirit halved and wood spirit itself is to be placed in a favourable position as regards duty and denaturing. As was seen by the passage from a speech by Mr. Austen Chamberlain which we quoted last week, the Government apparently take a favourable view of the committee’s recommendations.

* * *

Exactness in Formulæ. We have been privileged in our time to peruse some remarkable prescriptions, including those of “authorities” who will tell you to add ten drops of such and such a solution to one part of something else, but we do not remember to have come across quite such a gem of exact specification as one we found some time ago in a Belgian contemporary. The author, M. Maes, is giving his pet developer for lantern plates, and here is his formula:—

Rain water, 125 ccs.

Sodium sulphite (anhydrous), 1 mustard-spoonful.

Potassium carbonate (anhydrous), 1 mustard-spoonful.

Pyrogallol acid (Geka), 1 mustard-spoonful.

Potassium bromide solution (10 per cent.), 6 drops.

Glacial acetic acid, 6 drops.

We would point out that “Maes” is no misprint for Mees. If it were, any criticism of ours would be out of place, for with our own Mr. Kenneth Mees, as the author of this “formula,” the mustard-spoonful could safely be assumed to have a definite value. We cannot imagine Mr. Mees neglecting to standardise or calibrate a mustard-spoon, squeegee, niblick, garden roller, or anything that is his. In defence of the Belgian mustard-spoon as a measure of bulk, it may perhaps be urged by some that it answers the requirements of the particular case. We should not be surprised at our friend Mr. Thomas Bolas discovering wherein the mustard-spoonful surpasses the gramme and cubic centimetre as a measure. The point of view from which the difference between the litre and 1,000 ccs. (i.e. .15 c.c.), appears large enough for serious comment may perhaps disclose advantages of the mustard-spoonful, as also of the confusing English weights and measures, which we confess to be unable to discern. As another example of that looseness of diction or writing which is far too common, we noted that a writer in the “Daily Telegraph” of last Saturday says, in advising the use of the swing-back in order to get both foreground and distant objects in focus with a large aperture, that the use of the swing-back “increases the focal length.” Of course it does nothing of the kind, and although all photographers know what is meant, it is another good example of what we have been complaining of.

* * *

Enlargements. very advantageous arrangement can now be made with some of the best firms of enlargers for the supply of specimen pictures. In one case a well-known firm of carbon enlargers will supply £5 worth of pictures, which are *bona fide* approbation pictures or wall specimens, at a reduction of 20 per cent. In another case a special arrangement is made by a general enlarging firm to revise and renew specimens by arrangement at specially reduced rates. There can be little doubt that the public

taste is much better than it was, and the ordinary bromide enlargement is played out except for a cheap class of trade. Many people with money to spend in such things do not quite like to hang on their walls enlarged portraits, and we believe good business might be done in smaller enlargements rather more finely finished, and mounted as panel pictures or framed with strut backs, so as to stand on tables. Such pictures look equal to direct panels 15 by 9 or 17 by 12, and will command good prices, and frequently sell in duplicate or even more copies. We are not making the suggestion as a new one, as we believe some London photographers have done something on these lines, but we have heard of objections to enlargements on the walls, and in some provincial towns the idea might be successfully carried out. It would, at any rate, be talked about and so prove a good advertisement.

REPAIRING AND COPYING GLASS POSITIVES.

It not infrequently happens that a photographer has an old collodion glass positive brought to be copied, or to make an enlargement from. It goes without saying that a good glass positive, if in the condition it was in when first produced, is one of the easiest of all photographs to copy. But, as a rule, this is not the case. If they were good in the first instance they may have suffered through not having been varnished, or the varnish may have cracked, or they may have been injured by careless handling, or otherwise. Nevertheless they are often valued by their owners, and photographers frequently obtain substantial prices for well-executed enlargements from them. Many photographers of the present day are not familiar with the collodion positive process, or the excellent pictures that were produced by it in the “fifties”; and we have known instances where some have declined orders for enlargements on account of the state of the originals, while others have undertaken them and obtained high prices for the work, which to them has involved but little trouble.

A glass positive, it may be mentioned for the information of those who may not be aware of the fact, is, practically, a very thin negative backed up with some black material. Sometimes this was a piece of black velvet, at others it was a coating of black varnish. Sometimes the black material was applied to the film side of the plate and at others to the glass side. At times the pictures were varnished with a transparent varnish, at others they received no protection at all. In many instances when the varnishing was omitted the film became discoloured. Of course, when the picture has been backed on the glass side the image is reversed as regards right and left, as in the case of Daguerreotypes. The reason why this was done was that the image, as seen on the front of the film, was brighter than when seen from the back, or through the glass. Many of the black varnishes in use in the glass positive days would crack after a time, but the fissures are usually very fine. We will assume that a positive in this condition has to be copied.

If the varnish is on the back of the plate, the best way will be to scrape it off with a knife—it will be found to be exceedingly brittle—and apply fresh. If, however, it is on the film side his, it is manifest, cannot be done. The best procedure then is to carefully apply, with a brush, some fresh varnish, slightly diluted, over the old. This will fill up the cracks, and at the same time tend to bind the collodion film more closely to the glass, should it have a tendency to leave it. The picture may then be copied in the usual way with good results. It may, however, happen that the picture was not protected with varnish, and that the image has become discoloured to such an extent that a successful copy cannot be made in the

ordinary way. In such a case the black varnish should be removed from the back, when it will, usually, be found that the discoloration does not show by transmitted light. Then the picture should be dealt with as if it were a thin negative; but, as it is not varnished, it cannot be printed from by contact, by reason of the tenderness of the film. No attempt must be made to varnish it with the ordinary spirit varnishes, as the collodion has, in all probability, become so deteriorated that the spirit would partially dissolve it, and thus ruin the picture entirely. Even if it could be varnished the image would be too thin to yield a presentable print. The best way in such a case is to make a transparency in the copying camera, exposing and developing it so as to obtain as vigorous a result as possible, and then, from this transparency, to make a negative, again increasing the contrasts as much as may seem necessary. An alternative method, still using the picture as a negative, is to make an enlargement direct on bromide paper, work it up in black and white, and then make a negative from that. By either of these methods exceedingly good reproductions may be obtained from most unpromising originals.

In the foregoing we have assumed that the collodion has been intact so far as mechanical injury is concerned, but that is not always the case with old glass positives that have to be copied. We will here quote at some length a case that came under our notice some two or three years ago, as it may be of service to others in similar extremities. Calling one day on an old photographer, who, by the way, was quite familiar with the collodion positive process, we found him engaged on what almost appeared to be a hopeless job. He had the portraits—glass positives—of two children to make highly finished carbon enlargements from, for which some six guineas each were to be paid. The films had cracked and in some parts were detached from the glass, and they were so tender that they would be injured by anything but the most delicate treatment, yet he made light of the matter, though he said that some hours' labour would be necessary for the repairs. It may be well to explain the kind of pictures under treatment. They were of the five by four inch size, in

a double case, and had been varnished and backed with black velvet on the glass side, and were, or course, reversed with regard to left and right. They were also vignettied, a rare thing with glass positives, and evidently a good price had been paid for them in the first instance, as the case bore the name of a high-class photographer in the glass positive days. Our friend explained that the dilapidated state of the film was due to the pictures being taken on special and expensive colourless glass that was introduced for the purpose many years ago. It was, however, found, after a time, that by reason of the large amount of alkali it contained the glass "sweated" and absorbed moisture on its surface, hence the injury to the collodion film.

This is how the repairs were effected. The edges of the cracked film were carefully raised with the point of a penknife and touched with a weak solution of gum, and then pressed down again with a dry sable pencil. Detached portions were carefully matched and secured by the same means and allowed to dry. Then the fissures, and the portions from which small pieces were missing, were somewhat neatly filled in with flake white, toned down with colour to match the slightly grey or yellowish tint of the image. In applying this it was allowed to overlap to a slight extent to further secure the film to the glass. When this work was finished it looked very unpromising when seen from the film side, but on turning the pictures over so that they were seen from the glass side, the repaired injuries, and the overlapping colour, could only be detected by very close examination. A thin plate of plain glass was then bound on, round the edges, to protect the film from further injury, and the negatives made in the usual way. The pictures were returned to the case. They were, of course, reversed from what they were before, but this brought them the right way about as regards right and left (according to life), as they had previously been seen film uppermost, and the portraits still faced one another as before. The negatives when taken required but little or no retouching before they were enlarged, so adroitly had the repairs been done, yet no particular skill was involved in the work.

MICRO-ORGANISMS OF STARCH PASTE.

STARCH paste being the most popular medium for mounting photographs, the causes and effects of the decomposition of this mountant may prove interesting to photographers.

The chief objection to the use of starch paste is that it rapidly deteriorates when kept for some time, unless some disinfectant is added as a preservative. When starch has become stale a considerable portion of its adhesiveness is lost, and it becomes in course of time practically useless. On account of this objectionable feature of paste, text books always recommend the preparation of fresh mountant for each batch of prints. Other mountants besides paste turn "sour" when kept for any length of time. Gum and glue, for instance, become acid when stored in solution, but in these cases the adhesive properties of the substances remain almost, if not quite, unimpaired.

Infected Paste.

The reason of the inferior keeping qualities of paste is to be found in the fact that starch has a great attraction for certain kinds of both animal and vegetable organisms of an exceptionally destructive nature, and when a few wandering spores or germs alight on the paste, decomposition progresses very rapidly indeed, unless a preservative has been added to the mucilage.

When paste is prepared just before use, and the surplus

thrown away, no chance is afforded for the cultivation of germs. When, however, as in many business places, the paste-box is always in use, being merely replenished from time to time with fresh paste, a fine opportunity is given to study the growth of what are known to microscopists as "paste eels" and the rapidity with which they turn the fresh paste to a slimy mass with an unpleasant appearance and odour. Generally speaking, the cause of the deterioration of the paste is not known to those who use it, and they are not aware of the fact that the paste-box is thoroughly infected with the aforementioned paste eels. When the contents of such a box is examined closely it will be found, if the surface of the paste is viewed obliquely, that the whole of the mass is in constant motion, the animals themselves are too small to be seen individually with the naked eye, but the incessant activity of the mass of eels causes a slight flickering of the light that is reflected from the surface of the paste.

A very similar "eel" was formerly very commonly found in vinegar, but owing to the presence of a small percentage of sulphuric acid, and also to the absence of mucilage, in modern vinegar, this interesting animal is now rarely found. It is several years since the writer last saw some of these animals in a sample of vinegar, and several attempts to colonise some paste eels in vinegar were a complete failure, owing either to the

the fault of the animals, the vinegar, or the experimenter. The vinegar eel was the first of the order (anguillulidæ) to be discovered (in 1656), and the paste eel was found soon afterwards independently by several observers.

Paste Eels.

These animals were at first classed with the infusoria, but subsequently placed with the nematoid worms and termed

Fig. 1 ($\frac{3}{8}$ in. obj.).—Photo micrograph of eels in starch paste. Normal appearance under low power objective.

anguillulidæ. The paste eel is known as *anguillula glutinis*. The anguillulidæ are small (from 1-100th to $\frac{1}{4}$ in. in length) transparent worms, and various species are found in wheat, moss, water weeds, and damp places generally. One of the chief characteristics of these animals is that they are extremely tenacious of life. If the paste or any other substance they may inhabit is dried up, they remain dormant and apparently lifeless for several years, reviving immediately they are brought into contact with water. One observer claimed to have revived some specimens of *anguillula* after twenty-seven years quiescence.

The writer kept a piece of dried paste for three years, and the eels revived at once when a portion was placed in water; but a further trial of the same paste being made two years later, the occupants would not be resuscitated.

The word "dormant" hardly expresses the total absence of all evidence of vitality in the anguillulæ, when there is no moisture in their habitat, as that term is always associated with a continuance of the actions of the internal organs, however sluggish those actions may be; but in the anguillulæ all internal motion ceases, and organs of the animals remain in exactly the same condition during the period of quiescence, and the writer could not in the case just mentioned observe any loss of vigour or substance after a three years' desiccation. The eels are not exterminated by freezing, but become as active as ever when the temperature of their environment is raised above freezing-point. Under these circumstances, it will readily be understood that when once they have estab-

lished themselves in a paste-box they are not easily ejected, and although only an infinitesimal quantity of dried paste may remain, that is quite sufficient for all purposes, and eels will soon be wriggling over the whole surface of the paste when the box is replenished.

Preparing the Specimen for Photographing.

The paste eel is about 1-30th in. in length, the female being rather larger than the male. Being white and very transparent it is not easily seen with the naked eye, but is readily distinguished with a low power objective. Some preparation of the specimens is required before the eels can be seen to advantage under the microscope. A small portion from the surface of the infected paste should be taken on the tip of a knife and spread over a glass slip. When first inspected the result is disappointing (Fig. 1), but as the paste begins to dry the eels come to the top of the starch, and their movements can then be conveniently observed.

When the paste is quite dry the worms become motionless and appear lifeless, but if a drop of water be placed on the slide they immediately revive, and swim about with undiminished energy. As the colour, or lack of colour, of the paste is much about the same as that of the eels, very little can be seen of the actual structure of these animals by this crude form of examination; in fact, it is difficult to distinguish the head from the tail of an anguillula, and the internal organs are practically invisible.

Staining with Iodine.

Some method of staining the worms is necessary before the microscope can be used to full advantage. For the purpose

Fig. 2 ($\frac{3}{8}$ in. obj.).—Eels in starch paste. Starch stained blue with iodine, eels unstained.

of exhibiting the eels *en masse*, a great improvement is effected by adding a weak solution of iodine to the paste. This, of course, gives to the starch a deep blue colour, the anguillulæ

remaining white, or at the most being stained a light yellow colour.

Except with a very weak solution, iodine kills the anguillulæ immediately. The eels are then straightened out as seen in Fig. 2. When a colony of eels assumes this posi-

tion, it is a proof that they are dead, and not merely dormant. The effect of staining the paste with iodine is demonstrated in Fig. 2, which is a low power photograph of iodine-stained starch, the eels appearing as white threads on a dark ground. Fig. 1 shows the normal appear-

way or examined without mounting. The specimen in Fig. 3 was stained in this manner. Iodine staining, however, does not bring out the internal organs of the eels in a very satisfactory manner, as it stains all the tissues indiscriminately.

Hæmatoxylin as a Stain.

The writer found that a weak solution of hæmatoxylin did not destroy the animals, and if a small quantity of eel-infested paste is placed in that stain the worms remain alive for several days, swimming freely in the liquid. At first the exterior only of the eel is stained, but after a day or two the external stain almost disappears. By this time a considerable quantity of hæmatoxylin has been swallowed, and the internal anatomy of the animal is stained a bluish red, and is clearly visible under a high power objective. If the eels are allowed to remain too long in the staining bath they become decolorised again.

There will be numerous failures with this method before the correct strength of the stain and the time of immersion is found, and even then only a few in each batch of worms will be worth mounting. Considerably over a thousand specimens were stained and examined separately for the photographs shown here, but only three were mounted. When the staining is complete, the starch and logwood solution is transferred to methylated spirits and stirred up vigorously; in a few seconds the eels begin to settle to the bottom of the glass; the liquor is then poured away till only a few drops remain. These contain eels free from starch, and after another rinse

Fig. 4 ($\frac{1}{2}$ in. obj.).—Photo-micrograph of head of paste eel. Iodine-stained.

ance of the eels with the starch unstained; the eels can hardly be distinguished from the surrounding layer of paste.

In order to examine the worms with high powers they should be isolated and stained. The easiest method of separating and

Fig. 5 ($\frac{1}{8}$ in. obj.).—Photo-micrograph of paste eel (female). Internal organs stained with hæmatoxylin. Photographed in two parts.

colouring the eels is to pour a few drops of a strong solution of iodine, dissolved in water with iodide of potassium, on a portion of paste placed on a glass slip. The eels float off clear of the starch into the iodine solution. The latter is

in spirits they are ready for mounting. This method was adopted in preparing the specimen photographed in Fig. 5. It will be noticed that the outline of the eel is transparent; the internal organs, however, are deeply stained.

When a well-stained specimen is examined with a high power, it will be found that the mouth consists of a small round orifice at the extreme end of the eel's head. From the mouth the pharynx leads into the œsophagus, which bulges out into a bulb-shaped structure; the digestive organs, etc., terminate in the anal aperture, which is situated at a little distance from the end of the tail.

Fig. 3 is a photograph of a female anguilla, showing ova in ovary.

Fig. 4 shows the head portion of an eel. The mouth A leads into the pharynx and œsophagus, B C D.

Paste eels have no eyes, but some species of the anguillulidæ possess rudimentary organs of vision.

Fig. 5 is a reproduction of a female eel stained internally with hæmatoxylin. As a 1-12 objective was used for this photograph the worm had to be taken in two parts. The two photographs, it will be noticed, are joined together for reproduction. The mouth is shown at A, the alimentary canal being well defined through nearly the whole length of the worm, terminating at the anus C. The external aperture of the ovary organs is seen at B.

A remarkable feature of these animals is that though they live in a slimy mass of paste, yet they wriggle out of the mass

without a vestige of starch adhering to them; even the iodine test gives no blue discolouration to their bodies. There is a general opinion that these worms can only exist in sour paste; as a matter of fact the sourness is the result, not the cause, of their presence, and they breed far more rapidly in fresh than in stale paste.

Although the anguillulidæ multiply at an enormous rate under favourable conditions, they do not increase with anything like the same rapidity as many of the lower orders of animal life. The female rarely produces more than ten or twelve ova at a time, often only one or two. The ova are of large size, and arranged in a single row in the ovary.

Effects on the Mountant.

The occurrence of eels in paste is accompanied with the formation of a considerable amount of acid, chiefly acetic with a trace of formic. The question as to whether the permanency of the photograph is affected by being mounted with this acid paste is an interesting one. As the acid is not of a stable nature it might cause no ill effect on the image. As previously mentioned, the chief objection to the occurrence of anguillulæ is the loss of adhesiveness in the paste caused by their presence.

J. I. PRIGG, F.R.M.S., F.R.P.S.

PHOTOGRAPHERS' ADVERTISEMENTS.

SOME NOTES BY AN OUTSIDER

[The following paragraphs complete the comments of last week Mr. Casey's articles to which they refer appeared in the *BRITISH JOURNAL OF PHOTOGRAPHY* for March 24 and 31, and April 7.—Eds., B.J.P.]

Windows; 'M, Yes, but Postcards.

MR. CASEY rightly enough urges making the window attractive. "Show a view of the local footballers winning the goal," he urges. 'M, yes, certainly, but why not on sensitised postcards? Every postcard your own advertisement; not obtrusively, but necessarily.

My friend Mr. G. A. Atkinson, of Ulverton, photographed the train blown on to its side on the viaduct crossing the sands near Ulverston. The train was righted before another camera man came along. It paid splendidly. Atkinson sold thousands altogether. A very great many were sold at 4½d. each, I believe.

I am writing this note on April 8. Snow is here. It has come to make a sort of April fool of the spring. I looked out on early budding trees, full of small, bright, yellow-green leaves, with plenty of snow still remaining on palings and roofs. April snow is unusual. April snow has a selling and an advertising value. Did any reader of these notes recognise this? Did he photograph some interesting familiar spot in its April snow garb, and make some dated photographic postcards? Could an easier opportunity have come, both to rake in pence, and to stamp oneself with the character of uptaking alertness?

Photographer-Journalist.

Wanted in the photographer—something of the journalistic instinct. The Atkinson case illustrates this. 'But you can't always arrange for trains being blown over. Smaller affairs may serve. By keeping a sort of forward diary one can often tell what will be engaging the local mind next week or the week after. What faces will be in evidence. Be prepared. Be systematic in diary and other entries. Order makes for orders.

That Amateur.

Now just here I'm more diffident than usual. An unfeeling

editor has given me away as an outsider. And, anyway, I am not venturing to do more than suggest. But—but—why not specifically advertise for amateurs' work to be finished in your studio. Let them roll up with their films. Let them know that you do not give them away. You have a real dark room.

A catch wheeze for them occurs. Advertise that you serve amateurs, even very amateurs; that it is your pleasure. You will be getting a bit of your own back in advance.

Mr. Casey's Advertisements

Are well-panelled out, and illustrate the wisdom of white spacing. I think they are a bit too much alike. Avoid the monumental mason style, certainly. But there are various ways of doing this. Wording reaching across the column and then tapering away in an inverted pyramid would be one variant, having plenty of white and standing out from other advertisements.

Size of Advertisement.

"Ads" need not be large, and therefore can be inexpensive. But go in for two inches double column, as against four inches single column. If the advertisement is very small, have a block made. Say, a half-tone of open screen.

Two inches double column of a striking and original advertisement may pull far more business than a column, which is both commonplace in wording and indistinguishable from advertisements surrounding; I mean which is not easily picked out by the eye.

Change your Advertisements.

Some years ago I met a photographer thirty miles from London who was slack, slack, slack. Yet he had been established thirty years, and had done good work. He used to say in confiding moments, "I am glad I made my bit when I *could* in years gone by. I could not make it now." And that man did advertise to some extent, but he scarcely ever changed his advertisement, year in, year out.

Mounting.

The profit may come to the mounting, possibly either through

the interest created and extra value due to the adhesive dry mounting, or to your use of special cover papers. Get your printer to show you the cover papers of Lindenmeyer's or some like house. Lindenmeyer's would break a ream and supply a few sheets.

Railway Advertising

Will, I think, only be of much good if there are constant changes.

Town Improvement Associations

Can be promoted by a newspaper man, a photographer, an hotel-keeper and a few 'cute friends and neighbours getting

together, and they do good in all ways. They certainly must mean a good deal of photographing.

Finally there is the fake photograph. I do not know that that is not the best wine kept to the last. Get out a little booklet, entitled, "The Camera Cannot Lie;" and fill it with half-tones of local photographs, every one of which is an obvious lie; or if it be not obvious, let the letterpress explain the joke. Your advertisement would be in everybody's mouth; and after all that is a very large part of the art of advertising. We want to be *talked of*, and favourably; some people whom no one has anything against, are not talked of at all.

FRANK COLEBROOK.

THE WEEK IN HISTORY.

Fifty Years of Roll-film Photography.

THE junior in photography will no doubt take exception to my title of this paragraph, and he will not be very wrong in doing so. Historically and academically, the roll-holder celebrates a jubilee to-day, inasmuch as, on April 21, 1855, appeared in "Notes and Queries" the first description of an apparatus of this kind, devised by Captain Barr. The paper was printed in the first place in the "Journal" of the Photographic Society of Bombay, and was written by Captain Barr, in January, 1855. The apparatus is quite the counterpart of the modern roll-holder, yet nobody will be justified in dating the era of film photography back to this period or any further than about the year 1834, when the Eastman Dry Plate and Film Company, Ltd. (now Kodak, Ltd.) put the first "roll-holder" on the market and advertised it in THE BRITISH JOURNAL ALMANACK for 1835. Nevertheless, it is interesting to note in how many points the modern roll-holder tallies with Captain Barr's experimental "dark slide for the paper process," as he himself called it.

Describing his apparatus as a box containing two vertical rollers which can be wound by a key, thereby drawing the paper across a glass plate between them, he goes on:—"After the slide has been put into its place in the camera, the key for revolving the upper roller and the short roller are introduced in their places. The rollers are both fitted into the dark slide so as to be removable at pleasure. To use this dark slide, prepare your sensitive paper, say ten or twelve sheets; have a piece of thin black calico, a little longer, say, twelve inches longer than your twelve sheets of paper; and upon this band of black calico place your sheets of prepared paper, leaving intervals of about two inches between each two papers, and attach the papers in any convenient manner by their upper and lower edges to the calico. Now attach the one end of the calico to the lower roller of the slide and roll it up, leaving just sufficient of it unrolled to reach the upper roller; pass this unrolled end over the glass plate I have referred to, and then attach it to the upper roller. Shut down the sliding door, and place the slide in the camera; fit the key to the upper roller as directed, and the short outer roller to the lower one; over this short roller wind a piece of tape to the same number of times as the calico inside is wound, and you are then ready to proceed to work."

Captain Barr then directs the employment of the index tape to bring No. 1 of the sensitive papers into position. "The index tape," he says, "is of exactly the same length as the calico band carrying the paper, and, being placed alongside the band in the dark room, after the papers have been attached, it is marked off to correspond with the papers and

the position of each paper may be conveniently noted on it, as 1st, 2nd, 3rd, etc., thus:—

Black Calico Carrying the Prepared Paper.

Paper.	Paper.	Paper.	Paper.
Index Tape.			
4th.	3rd.	2nd.	1st.

"As a further precaution against light, and to guard against the evil effects of air upon the prepared paper, I leave the calico band a foot longer than is necessary to carry all the papers. So that, when all are wound round the roller, the last five or six folds are plain calico, thus excluding light. I take the roller thus prepared out of the dark slide, and place it in a round metal case, which has a top which screws on airtight. In the centre of this top is a short tube, opened and shut airtight at pleasure by a small stop-cock. To this tube I attach a small suction-pump, and, after all is thus prepared, I introduce the roller with the prepared paper into the metal tube, screw on the top, and exhaust the air. . . . As a precaution against heat I cover the metal tube in a case of damp cotton cloth covered over with a dry piece of woollen cloth or flannel."

A year later, on the same date, April 21, on which Barr's roller-slide was described in "Notes and Queries," a similar apparatus was the subject of a letter, in "The Photographic Journal," from A. J. Melhuish, who three years previously had patented a type of roller-slide very similar to Captain Barr's, and, like his, provided for daylight changing. "The object of the slide," writes Melhuish, "is to enable a person to carry any number of sheets of sensitive paper and change them conveniently in the open light. The slide is fitted up with two rollers, and the sensitive sheets are gummed together, making one long band, the ends of which are gummed to pieces of paper always kept on the rollers." The sensitive sheets are wound off the left or reserve roller on to the right or exposed roller until all are exposed. . . . There are doors by opening which the operator can see (through the yellow glass) to adjust the position of the sensitive sheets when changing them.

Fox-Talbot's Photogravure.

Forty-seven years ago to-day Fox-Talbot took out the second patent for the process to which he gave the name of "photographic engraving,"—which process was photogravure in almost

exactly its present form. His patent specification, No. 875, 1858, is quite a small treatise on the process. It explains how the image on bichromated gelatine is etched into the metal plate without first washing the exposed plate in water or alcohol and it further sets forth the formation of an aquatint ground of resin on the gelatine surface, not on the uncoated metal plate:—"When the plate bearing the photographic image is removed from the copying frame, I spread over its surface, carefully, and very evenly, a little finely powdered gum copal (in default of which common resin may be employed). It is much easier to spread this resinous powder evenly upon the surface of the gelatine than it is to do so upon the naked surface of the metal plate. The chief error the operator has to guard against is that of putting on too much of the powder. The best results are obtained by using a very thin layer of it, provided it is uniformly distributed. If too much of the powder is laid on, it impedes the action of the etching liquid. When the plate has been thus very thinly powdered with copal, it is held horizontally over a spirit-lamp in order to melt the copal. This requires a considerable heat. It might be supposed that this heating of the plate, after the formation of a delicate photographic image upon it, would disturb and injure that image, but it has no such effect; the melting of the copal is known by its change of colour; the plate should then be withdrawn from the lamp and suffered to cool. This process may be called relaying an aquatint ground upon the gelatine, and I believe it to be a new process."

Talbot also claimed the use of perchloride of iron as an etching solution to be new, and he directed the use of several baths for the etching of a single plate, as is now the practice of photogravure plate-makers.

Progress in Wet Collodion.

The wet-collodion process as worked out by Scott Archer has already been recorded in this series of retrospectives ("The Week in History," February 24), and I have also referred to the efforts made to permit of the sensitive plate being kept for a considerable time before exposure. Girod and Gaudin, in France, tried cumbrous mechanical means of arresting the eva-

poration of the liquid on the plate ("The Week in History," March 17), but a year later, and fifty-one years ago to-morrow, Gaudin described in "La Lumière" (of April 22, 1854) how he found it possible to prolong the life of the plate by washing in distilled water after sensitising. He claimed to find no difference in sensitiveness between the two halves of a sensitised plate from one of which the silver nitrate had been got rid of by washing in distilled water, and the absence of the silver salt made it possible for the plate to be kept for twenty-four hours between sensitising and exposure. Gaudin attributed the loss of sensitiveness in the ordinary process to the change of the silver nitrate, the solution of which on the plate becomes more concentrated by evaporation of moisture, and thus dissolves the silver iodide. Gaudin likewise turned to sugar and other substances for preserving the collodion plate in such a state of semi-dampness that the silver nitrate would not crystallise, and here we see the beginnings of the endless dry-plate bath processes for which "preservatives" were taken from the most motley collection of substances—isinglass, albumen, gum in fact, any innocuous substance which would dry without crystallising, and would serve as the vehicle of the silver nitrate. A process by John Spiller and William Crookes was prominent at this time, and will come up for mention shortly.

Fixing with Cyanide.

Who first used potassium cyanide as a "fixer" of plate or print? Was it M. Gaudin who recommends it as an improvement on hypo in "La Lumière" of April 23, 1853? He is writing of the best way to obtain a brilliant white deposit of silver in making the direct collodion positive, which at that time was a very popular form of "print," and he favours the addition to the iron developer of potassium cyanide in minute proportions. He then proceeds: "Negatives for printing on paper are usually fixed in hyposulphite of soda in a way that leaves a faint opalescence in the high-lights. It is said that they print better when of this character, but I am by no means convinced that this is so; and if, as I suspect is the case, it is not correct, a solution of cyanide, one part in a thousand, will be more convenient and economical."

HISTORICUS.

INDUSTRIAL ALCOHOL.

The Report of the Government Committee.

On Friday last, April 14, the Committee appointed by the Chancellor of the Exchequer to inquire into the use of alcohol for industrial purpose free of duty published its report. (Wyman and Sons, London, E.C., 3d.) The Committee had instructions:—

(1) To inquire into the existing facilities for the use, without payment of duty, of spirits in arts and manufacture.

(2) To report whether the powers given to the Commissioners of Inland Revenue by Section 8 of the Finance Act, 1902, provides the necessary facilities for the use of spirit in manufacture.

(3) To advise further measures (if such should be necessary) without prejudice to revenue from spirits, and with regard to the interests of producers of spirits in the United Kingdom.

Existing Legislation.

Under the present law (Spirits Act, 1880, Customs and Inland Revenue Act, 1890, and Section 8 of Finance Act, 1902) the administration as to the use of spirit in industry is as follows:—

Manufacturers can use, under Excise supervision, and in large quantities, spirit mixed with one-ninth its bulk of wood naphtha (i.e., "ordinary" methylated spirit).

Since 1902 manufacturers have also had the privilege of themselves "denaturing" (or rendering unfit for human consumption) spirit em-

ployed for a particular process, in a way suitable to the particular purpose, should the Board of Inland Revenue consider such a course necessary.

"Ordinary" methylated spirit, plus .375 mineral naphtha (petroleum) and known as "mineralised" methylated spirit, is the only spirit which can be supplied retail.

Variable "Denaturing" since 1902.

Properties and price are the two objections to the "ordinary" methylated spirit. The 10 per cent. of wood naphtha is unsuitable for many purposes, and its cost is more than double that of the alcohol which it replaces. The Committee claim that the provisions of Section 8 of the Finance Act of 1902 removes the first of these objections and mitigates the second, inasmuch as it provides for denaturing by special agents which commonly cost less and permit also of the production of denatured spirit fit for any manufacturing process. The provisions of the Act, it is thought, are very imperfectly appreciated.

The question of price is viewed by the Committee as far more serious than that of quality, and it is shown that under the conditions under which spirit is made and taxed, the price of a bulk gallon of spirit is 5d. more than it would be were there no Excise restrictions, to which 3d. or 4d. has to be added for methylating, so that of the 20d. or 22d. paid per bulk gallon at wholesale price, 8d. is Revenue charge.

Alcohol and Crippled Industries.

From the evidence before it, the Committee finds the commonly-repeated assertion, that the coal and tar colour industry has been lost to the country through obstacles to the use of alcohol, to be destitute of substantial foundation, though two members dissent from this view. Yet they recognise the difference in the colour industry to-day, and conclude that greater licence is needed in the use of spirit, more so for methyl alcohol (wood spirit) than for ethyl alcohol.

In other branches of manufacture, fine chemicals, smokeless powders, lacquers, varnishes, and artificial silk, the restrictions on the use of spirit are such that the manufacture is commercially impossible.

Recommendations.

The general conclusions of the Committee can be summarised as follows:—

For general public use the present "mineralised" spirit cannot be improved. The regulations as to the stock which may be kept by retailers or quantity which may be sold at one time to a customer may be relaxed.

For industrial purposes the Finance Act gives every facility in respect of producing spirit suitable for any industrial purpose.

In the matter of price, the Finance Act does not bring the cost of "denatured spirit" within possible limits. The way in which the Excise restrictions can be modified is by neutralising, for industrial spirit, the enhanced cost of production, due to Excise control, as is done for export—viz., by granting an allowance on such spirit at such rate as may from time to time be taken as the increase in cost of production due to Revenue restrictions. At present the rate is 3d. per proof gallon for plain spirits. The manufacturer should bear the cost of denaturing to the extent of providing the agents and mixing them with the spirit.

"Ordinary" methylated spirit may be modified to consist of 95 volumes of spirit to 5 of wood-naphtha. This will cheapen it, while still "ear-mark" it for Excise supervision.

Methyl-alcohol may be exempted from the surtax of the proviso to Section 8 of the 1902 Act, whilst being denatured so as not to impair its purity.

Special denaturing agents for use in particular industries should be subject to official test.

These regulations should give manufacturers spirit at a price as low as the minimum price in Germany during 1902, when spirit was abnormally low.

German Conditions.

A sub-committee (Dr. Thorpe and H. W. Primrose) visited Germany in the interests of the inquiry, and their lengthy report is interesting as showing that no duty-free spirit is used in manufactures in Germany without undergoing some process of denaturing, except in the case of smokeless powder. The methods of "complete" and "incomplete" denaturing are stated as follows in the report, and the

details may serve to remind manufacturers of the facilities granted to them under the Finance Act.

The processes authorised for "complete denaturing" are two, viz.:—

(a) An admixture with every 100 litres of spirit of $2\frac{1}{2}$ litres of a mixture containing 4 parts of wood naphtha and 1 part of pyridine bases. (To this mixture 50 grams of lavender or rosemary oil may be added optionally, to counteract the smell of the pyridine bases. But the addition is seldom made.) Spirit thus denatured is what is used for domestic purposes—heating, lighting, and cooking. It is seldom used for industrial purposes. The only purpose of that kind for which its employment is considerable is the manufacture of cheap varnish.

(b) An admixture with the spirit of half the quantity (viz., $\frac{1}{2}$ litres per 100 litres of spirit) of the above denaturing mixture, together with an addition of $\frac{1}{4}$ litre of a solution of methyl violet dye and of benzol in quantities that may range from 2 to 20 litres to every 100 litres of spirit.

The spirit thus denatured is used in practice almost entirely for agricultural engines, as no satisfactory solution has yet been found of certain difficulties which beset the use of spirit for motor cars.

The processes authorised for "incomplete denaturing" are numerous. They consist:—(a) Of two alternative processes of general application, viz.:—The addition to every 100 litres of spirit of either 5 litres of wood naphtha, or $\frac{1}{2}$ litre of pyridine bases. (b) Of numerous processes of special application. But the processes applicable to the most numerous and most important industries including coal tar colours and chemical preparations, are the four alternatives of:—An addition to every 100 litres of spirit of 10 litres of sulphuric ether, or 1 litre of benzol, or $\frac{1}{2}$ litre of turpentine, or .025 litre of animal oil.

We may observe that the above regulations are applicable only to ethyl alcohol. Methyl alcohol does not fall within the charge to spirit duty in Germany, and may be used freely for industrial purposes, without control by the Revenue authorities.

The schedule of authorised denaturing agents cannot be varied by the Executive. Any amendment of it, or addition to it, must be sanctioned by the Bundesrath, or Federal Council of the Empire; and the procedure for obtaining such sanction occupies many months, probably never less than six.

The Revenue authorities regard them as being as little stringent as is compatible with the safety of the spirit revenue, even with the present low duty on spirit. They considered that, if the duties were ever to be raised, it would be necessary to revise the regulations, and to make them less lenient in certain directions.

For lacquer-making a considerable quantity of wood naphtha denatured spirit is used in Nuremberg, Baden, and Bavaria. Elsewhere turpentine is almost universally employed as the denaturing agent. No lacquers, polishes, or varnishes can be made in Germany with pure duty-free spirit, or with admixture only of shellac.

Photographic Collodion.—It is the common opinion in Germany that the British-made collodion is better than the German.

THE writer on photographic topics in the "Morning Post" decided last Saturday that our reference a month ago to certain dangers which rumour had associated with the mercury-vapour lamp, is the discovery of a mare's nest. Appreciation like this from an authority is inexpressibly gratifying. Are we to understand that the writer is now so certain of his facts—which, by the way, he presumably obtained from our own pages—that he is ready to stand alongside an active mercury-vapour lamp and let somebody smash it? Should the experiment be made, and further confirm the assurances of safety put

forward by Mr. Bastian and the Westinghouse Company, the "Morning Post" may be certain that our regret for our wrong statement will be deeper still.

"LIZARS' Magazine" (J. Lizars, 71, Bold Street, Liverpool) makes its appearance from the Liverpool house of the well-known Glasgow firm, and will frame its monthly programme more particularly with regard to the interests of amateur and professional photographers in that district. The first number foreshadows a cordial reception for the little journal, which is sent free on application.

Photo-Mechanical Notes.

The Debt of Three-colour to the Fine etcher.

At the recent exhibition at the Portman Rooms an opportunity was afforded of seeing projected some of Dr. Mithé's three-colour studies. The projection method with suitable apparatus such as was used, probably offers the ideal method of showing as favourably as possible the value of any set of three-colour negatives. Several of the subjects shown are quite familiar from half-tone reproductions issued as supplements to photographic and other magazines, and sold as post-cards, and to the mind of the writer, in every case the three-colour block was superior to the three-colour projection. The reason for this can only be that the block reproducers have had the opportunity at many stages (but perhaps chiefly in the fine etching) to manipulate the work until the colour rendering was correct, or at least extremely pleasing, an opportunity that does not occur, in such a practical way, in the projection method.

A Point About the Mercury Vapour Lamp.

The mercury vapour lamp is now being introduced for photo-engraving purposes, but even its advocates admit that it is no good for colour work. Yet, in effect, all half-tone reproduction is colour work, inasmuch as it should mean the rendering from a printing surface of the tones of the copy as seen by the eye. But the photography of these tones with a mercury lamp is effected by the ultra-violet light, to which the plate is specially sensitive, but to which the eye is blind, so that unless the absorption and reflection of ultra-violet light from the various tones of the original happens to correspond with that of homogeneous white light as perceived by the eye, the photograph will not be truthful. It is very seldom that this is likely to be true. In the case of bluish originals, more ultra-violet light will be reflected, and they will then reproduce flatter than they appear to the eye; in the case of greenish or reddish originals, more of such light will be absorbed, and they will probably appear more contrasted.

In the case of the ordinary arc lamp it is possible to make compensation by the use of a colour filter, but if the more refrangible rays are cut off from the mercury vapour light, it could probably make exposures so long as to be impracticable. For black and white line work these objections do not apply, but already exposures are so short in line work as to embarrass the operator with the small latitude for error, and most firms could not care to instal these lamps for line work only. Where, however, large line work has to be photographed, as in the reproductions of maps and plans, where hitherto there has been distinct difficulty encountered in securing even illumination, it would seem that the mercury vapour lamp would satisfy the long-felt want."

M.P.S.

"Our Navy and our Army" is the title of an interesting little pamphlet sent to us by Mr. Drinkwater Butt, F.R.P.S. It deals with the popular cinematograph entertainments organised by Mr. J. West, of Cinthesa, and known as West's "Our Navy." This well-known exhibition of life in the Services has probably done more for this country to quicken the interest of the public in the welfare of our "lads in blue" than any other conceivable method of illustrating the life of the man behind the gun, to save nothing of his brother the stoke-hold. Mr. Drinkwater Butt informs us that he is now attached to the staff of "Our Navy" for the purpose of doing special photographic and literary work in connection with the forthcoming Naval Exhibition at Earl's Court, and with the Nelson Centenary, which takes place this year.

Exhibition.

BRIGHTON CORPORATION EXHIBITION OF BRITISH PICTORIAL PHOTOGRAPHY.

THIS exhibition, to which we referred a few weeks ago, was opened by the Mayor of Brighton on Monday, April 17, and will remain open free to the public till June 3. There will be, therefore, plenty of opportunity for every one to visit what is undoubtedly a very fine collection of photographs. It is contained in the Corporation's new art galleries in Church Street, which, being spacious and well lighted, are admirably adapted for the purpose. The Fine Arts Committee of the Corporation secured the assistance of the Hove Camera Club and appointed a sub-committee, consisting of Messrs. G. de Paris, W. Clarkson Wallis, E. Davey (representing the Corporation), and Charles Job and A. R. Sargeant (representing the Camera Club) to carry out the arrangements.

It will not be necessary for us to attempt here a criticism of the pictures, as practically all have been exhibited in London previously. In looking through the list of exhibitors, we find few of the prominent exhibitors' names absent, and we are asked to give the thanks of the committee to all who have so generously lent examples of their work in reply to the invitation sent.

A. Horsley Hinton has sent five large landscapes, including "Fleet- ing and Far" and "To the Hills." J. Craig Annan, five portraits, including "Frau Muthasius" and "E. J. Frampton, R.A." A large birch and bracken subject, "Autumn," by W. Thomas, centres the left wall in the first room, with two splendid gum prints by Charles Moss close by. E. R. Ashton has five of his well-known Indian scenes. J. C. S. Mummery, four small gum prints, of which "Near Amberley" holds its own with anything in the exhibition. Mrs. E. H. Barton, several of her figure studies; and F. J. Mortimer five seascapes. J. C. Warburg and Miss Warburg are both represented; and Mrs. Carine Cadby, Reginald Craigie W. Crooke, Charles Job, and F. H. Evans have sent some of their best work. We might continue, but so much will prove that the dwellers in the south will be well repaid by a visit to the Brighton Exhibition during the next six weeks. It would appear that a good many sales will be effected, as four pictures were sold before the doors were actually opened. We congratulate the Corporation of Brighton on their enterprise.

New Materials.

The "Ideal" Plates and Papers. Sold by O. Sichel and Co., 32, Bunhill Row, London, E.C.

The "Ideal" plates are made in two rapidities. The Ordinary are recommended for all work where rapidity is not essential, while the Special Rapid, a sample of which has been sent to us, is quick enough for all instantaneous work and rapid exposure in the studio. They develop readily and without fog with any of the usual developers, and density is easily obtainable. The "Ideal" Collodio Chloride Paper (matt) is admirably adapted for obtaining sepia and red chalk tones, while the "Ideal" P.O.P. and post-cards are likewise reliable products of this firm.

Other papers of equal merit supplied by Messrs. Sichel and Co. are "Ideal" glossy and matt bromide papers, and "Ideal" gaslight papers.

The "Lisle" P.O.P. Sold by A. Curtis, 1, Meadowcourt Road, Lee, S.E.

A sample of this new P.O.P. has been sent to us, and it appears to sustain all that the maker claims for it. The paper is extremely white, and the whites remain pure throughout the subsequent operations. It prints quickly, and tones readily in the usual sulphocyanide and gold bath. In the phosphate borax bath it yields good rich brown tones, with no indication of double toning.

New Books.

"The Barnet Book of Photography." Eighth edition. Price 1s. 6d.
Published by Messrs. Elliott and Sons, Limited, Barnet, Herts.

A great army of photographers must exist to-day who owe Messrs. Elliott and Sons a debt of gratitude, apart from whatever satisfaction the employment of Barnet plates and papers has conferred. It does not need the assurance of the famous Hertfordshire firm that "the seven previous editions of the 'Barnet Book' have met with an unprecedented sale" to persuade us that in the eighth and present edition full value for money is being given. That the book is ostensibly produced as an advertisement does not detract from its value one iota, but rather is something for its readers to be thankful for, otherwise it would probably never have been produced at all, or, at least, not at the price at which it has been offered to the public during the past eight years. The present edition, styled the "twentieth century edition," is in every respect an entirely new work. New articles, new authors, and new pictures are presented in the manner made familiar by the previous editions, but the whole book has been recast and reprinted in a style worthy of a firm that has always been to the fore in tasteful representation where publicity is concerned. For the modest outlay of eighteenpence every photographer can now make an addition to his library that is not only a presentable and well-gotten-up volume, but is a work that forms a valuable addition to, instead of a substitute for, the previous editions of the "Barnet Book." Three hundred and twelve well-printed pages are occupied with practical and informative articles on photographic methods and matters. A. Horsley Hinton treats of "Negative Making" and "Pictorial Photography," subjects on which he is well qualified to speak. "Orthochromatic Plates and Colour Screens" find a capable exponent in John McIntosh. Percy G. R. Wright discourses on "Film Photography," and S. L. Coulthurst applies his practical experience in an article on "Lantern Slide Making." C. Winthrop Somerville and Thomas Manly deal with the subjects they have made their own—viz., "Bromide Printing" and "Ozotype" respectively; while "Hints on Amateur Portraiture" is in the Rev. F. C. Lambert's best style. Edgar H. Carpenter descants upon "The Hand Camera" and its manipulation, and Henry W. Bennett leaves very little to learn regarding "Carbon Printing." "Photographic Lenses" are fully dealt with in a practical manner by C. Welborne Piper, and the heart of the anti-fuzzite will rejoice at the concise pronouncements of W. E. A. Drinkwater on "P. O. P." Ten pages of useful formulæ help to swell the assemblage of good things provided, and the well-arranged index will assist in finding them. Not the least attractive feature of the new "Barnet Book" is the illustrations. They are not only good pictorially, but they are excellent examples of the process man's art, and do full justice to the pictures reproduced.

The praiseworthy modesty displayed by Messrs. Elliott in the production of the book is meritorious under the circumstances. Beyond an occasional inset and the usual space at the end of the volume, the temptation has been withstood to take advantage of a unique opportunity for "booming" Barnet goods. That this reticence will be appreciated and bring its own reward we are fully convinced, and cannot do better than quote from the firm's own words, contained in the preface:—

"We want the 'Barnet Book' to remind photographers throughout the world of our readiness to realise their needs, and to afford them help and advice in a manner not perhaps usual with a commercial firm; moreover, this book should keep in remembrance that vast and growing industry whence plates, films, papers, carbon tissues, etc., bearing the name of 'Barnet' are sent forth."

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

The following applications for patents were made between April 3-8, 1905:—

PRINTING APPARATUS.—No. 7,200. "Improvements in apparatus for printing photographic papers, opals, and the like." Scott's Studios, Ltd., and Charles Townsend Fox, 37, King Street, Covent Garden, London.

CAMERAS.—No. 7,202. "A collapsible photographic camera for use as hand or stand with either glass plates, roll or cut films." William John Robert Butler, 36, Tranton Road, Bermondsey, London.

CAMERAS.—No. 7,262. "Improvements in or relating to photographic cameras." George Wishart, 96, Buchanan Street, Glasgow.

DEVELOPING WITHOUT DARK ROOM.—No. 7,319. "Improvements in or in connection with developing or otherwise treating photographic plates and the like, without the use of dark rooms." George Edward Hawkes Rawlins, 6, Lord Street, Liverpool.

PIGMENT PAPER.—No. 7,341. "Improvements in and relating to the manufacture of photographic pigment paper." Thomas Walter Harding Jones, 7, St. Augustine's Road, Edgaston, Birmingham.

MAGIC LANTERNS.—No. 7,388. "Improvements in magic lantern apparatus." Thomas Edwin Bownes, 15, St. James' Row, Sheffield.

CINEMATOGRAPH APPARATUS.—No. 7,482. "Improvements in cinematograph apparatus." Claude Kennedy Mills, 23, Southampton Buildings, Chancery Lane, London. (Société Anonyme des Plaques et Papiers Photographiques, A Lumière ses fils, France.)

COMPLETE SPECIFICATIONS ACCEPTED.

Specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

CAMERAS.—No. 4,298, 1904. Relates to improvements in and connected with photographic cameras. A folding camera on the mirror or reflex principle in which the mirror and ground glass are folded back against the shutter of the dark slide within the camera bellows, which are collapsible. The bellows are kept rigid, when open, by an articulated folding spring, which also holds the apparatus closed. Further a metal blind shutter, with aperture capable of regulation outside, with two rollers, which are placed at the rear of the apparatus with a space in between them for a film or plate magazine, which allows of the passage of the blind in very close proximity to the sensitive surface. Félicien Blanpain, 11, Rue Dumonceau, Brussels.

LIGHTING.—No. 18,099, 1904. An improved method of lighting for photographic purposes. This invention is intended to ensure uniform lighting of objects to be copied, and in his preamble the inventor states that "considerable difficulty has been experienced hitherto in uniformly lighting large surfaces such as drawings, wall-coverings, reliefs, etc., for the purpose of photographing them. This uniform lighting has been impossible particularly in studios, the side towards the upper or side lights being always more fully lighted than the side towards the floor or the wall. Moreover it has been found impossible to ensure uniform lighting by means of sources of

light or reflectors arranged near to or behind the photographic camera. According to the present invention uniform lighting is ensured by the employment of a method which consists in a precisely determined movement of the source of light." One or more sources of light which are shut off in the direction of the objective are moved over the object between the object and the objective, that is, through the space which is formed by lines supposed to be drawn from the objective to the limits of the object so that all parts of the object are not photographed simultaneously but the different parts thereof in succession. For illuminating transparent surfaces, one or more sources of light pass with a certain regulated movement behind the transparent surfaces so that the different parts of the surface are photographed successively. Further, the alteration in movement is replaced or supplemented by alteration of the intensity of the light during exposure. Objects may be placed concentrically around a panoramic camera and the lights and slit of the camera be synchronously moved over the sensitive surface, or the object and sensitive film may be moved, whilst the objective and light remain stationary; further, the slit may pass in front of the sensitive surface instead of the object. Dr. Eduard Mertens, 7, Kleistrasse, Charlottenburg, Berlin.

WE have received the current wholesale price-list of chemicals and photographic solutions of Messrs. Harrington Bros., 4, Oliver's Yard, City Road, London, E.C.

PHOTOGRAPHIC Beauty Spots.—A writer in the "Newcastle Chronicle" observes:—"I think the English Lakes the ideal photographic district in the country, and there is no more suitable time for a short sojourn in the land of the poets than Easter. Ambleside is about the best centre, as coaches run to all parts, and it lies in the heart of a choice photographic locality. For wilder and perhaps grander scenery the Borrowdale end of Derwentwater is very hard to beat. Patterdale on Ulleswater (the English Lucerne) is also noted far and wide. For those who cannot get so far away at Easter, there are many places within easy reach of Newcastle well famed as photographic districts. The North Tyne about Chollerford is certainly worth visiting. Brampton, with Naworth Castle, Lanercost Abbey, Tarn and woods in the immediate neighbourhood offers good opportunities for picture-making. A few days could be spent to good advantage at Barnard Castle, or the Tees Valley. To photographers gifted with a little superfluous energy and desirous of combining their hobby with a little walking exercise, I cannot recommend anything better than Blanchland. By raining to Shotley Bridge and walking across the moors to Blanchland (ten miles), and putting up at this very quaint old village for a few days, a capital holiday can be spent. The return journey should be done via Riding Mill, also a ten-miles' walk. I know from experience the above places to be suitable for photographic work."

A copy of the thirty-ninth volume of the "Homeland Handbooks" series has reached us from the publishers, The Homeland Association, Ltd., 22, Bride Lane, Fleet Street, E.C. Seaford and Newhaven is the district dealt with, and in a chatty, instructive way the beauties and places of interest in the locality are brought to the attention of the reader. This series of books is an admirable one for the photographic tourist to possess, and they are not dear at all, each.

New Society.—It has been decided to form a photographic society at Eccleshill, to be known as the Eccleshill and District Camera Club.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

April.	Name of Society.	Subject.
21.....	Stirling and Dis. Photo. Club...	Exhibition Opens. Competitions:—Prints—Indoor Portraits, Outdoor Portraits, Bromide Prints Direct Enlargements, Mounting, Methods of Control, Pictorial Postcards; Decorative Photography; Slides—Architectural Detail, Agriculture, Clouds, Sea Shore, Still Life, Telephotography, any other subject, Natural History.
21.....	Aberdeen Photographic Assn....	Fourth Annual General Meeting. Some New Printing Processes. Demonstrated. Mr. A. Mackenzie. Beginners' Night.
25.....	Glasgow Southern Photo. Assn.	Westminster Abbey. Mr. H. W. Fincham.
25.....	Perthshire Soc. of Nat. Science	Photography 1904 Prize Slides.
26.....	Sefton Park Photo. Society.....	Exhibition Opens.
26.....	North Middlesex Photo. Soc.	Exhibition Opens.
26.....	Cricklewood Photo. Society.....	Annual Meeting.
26.....	Larktail Camera Club.....	
26.....	Barnhead Amateur Art Club ..	
26.....	G.E.R. Mechanics' Institution	

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

A MEETING of the general committee was held at 51, Baker Street, W., on Friday, April 14. Present, Messrs. F. A. Bridge, E. C. Elliott, S. H. Fry, William Grove, H. E. Hall, M. Jacollette, A. Mackie, H. S. Mendelssohn, D. Prodder, E. Scamell, H. C. Spink (Brighton), Lang Sims, and Fellows Willson. Mr. E. C. Elliott in the chair. The hon. secretary was desired to express the regret of the meeting at the absence of Mr. Alfred Ellis through indisposition. A discussion took place on the desirability and best method to be adopted of notifying members of the proceedings of the committee, and the work being done by the association. It was pointed out that the report of the committee meetings, which THE BRITISH JOURNAL OF PHOTOGRAPHY was good enough to insert, was necessarily brief, and could not include many items which it was desirable that members should be acquainted with, but which, for obvious reasons, could not be published to the world. A suggestion was made of the issue to members of a quarterly circular, to contain, as well as full reports of meetings, particulars of cases and other matters likely to be interesting or instructive. Further consideration of the matter was deferred to the next meeting. Further discussion took place on the suggestion to institute associateships for assistants holding certificates. The general principle was agreed to that they should be granted the privileges enjoyed by members except the right to vote or otherwise take part in the management of the association. As the matter would entail an alteration of the rules, and would have to wait, therefore, for the annual general meeting, it was agreed to bring the matter up from time to time for the consideration of details. Attention was directed to letters which had appeared in the correspondence columns of THE BRITISH JOURNAL OF PHOTOGRAPHY respecting assistants' certificates, and the hon. secretary was desired to reply as occasion required. An application from the Artistic Copyright Society for the subscriptions of the three members representing the Association was deferred for information as to the work of that Society. Several letters from members, and other correspondence was dealt with, and routine business was transacted.

MANCHESTER AMATEUR PHOTOGRAPHIC SOCIETY.—The monthly meeting of this society on Tuesday last at the Manchester Athenæum was arranged as an exhibition of hand cameras and hand camera work. The President, Mr. S. L. Coulthurst, had got together an excellent collection of examples by many prominent hand camera workers, and enforced the display by a paper on the subject. His preference was for the old-fashioned box-form of camera, which, although clumsy-looking, yet for serious work was unrivalled, although its possibilities were not so great as the many elaborately

fitted folding instruments now in the market. A series of demonstrations, particularly intended for beginners, has been arranged to take place at the society's rooms during the summer season. One of the series was given on Saturday, the 8th inst., by Mr. T. Longworth Cooper on "Photography in the Studio," and was followed with great interest by a large audience.

STANLEY CAMERA CLUB.—A lecture and demonstration on the Watkins' system of time development was given before the members of this society on Tuesday of last week by Mr. W. Peacock.

BATH Y.M.C.A. CAMERA CLUB.—This club held an exhibition of members' work at the Jubilee Hall, Bath, last week. There were 350 exhibits in competition. Mr. Hellis Davies was the judge.

HILLSBRO' AND DISTRICT PHOTOGRAPHIC SOCIETY.—The annual social of the above society was held on Wednesday, April 12, in Wycliffe Hall, Channing Street, Sheffield. A very pleasant evening was spent.

COVENTRY PHOTOGRAPHIC CLUB.—The annual meeting of this club was held on Wednesday evening of last week. A very satisfactory report and balance-sheet were presented, and great satisfaction was expressed that the recent exhibition of members' work had proved successful, financially and otherwise. The following officers for the ensuing year were appointed: President, H. D. Waters; vice-presidents, E. F. Peirson, J. I. Bates, B.Sc., W. H. Clarke, and E. H. Cooke; hon. vice-presidents, H. Rotherham, A. Seymour, F. T. Mercer, and A. L. Bill; committee, A. W. Hoare, H. J. Goodwin, M. W. Danks, and W. Riley; treasurer, A. B. Clarke; secretary, W. H. McLauchlan; auditors, W. Nelson and W. R. Harris.

SHEFFIELD PHOTO COMPANY.—The fourth annual exhibition and conversazione promoted by this company was held at Cutlers' Hall, Sheffield, on April 12 and 13.

NEWCASTLE AND NORTHERN COUNTIES' PHOTOGRAPHIC ASSOCIATION.—"Photomicrography" was the subject of a lecture delivered to the members of this association on Tuesday last by Mr. T. L. Hughes at the Y.M.C.A. Buildings, Newcastle.

COATBRIDGE PHOTOGRAPHIC ASSOCIATION.—At the annual general meeting of this association, held in the Photographic Institute, Wood Street, Coatbridge, on Thursday of last week, satisfactory reports were presented by the Hon. Sec. and Hon. Treasurer, and the former (Mr. G. W. Campbell) stated that they could offer facilities for photography which no society outside of London could give. The office-bearers for the ensuing year were elected as follows:—Hon. President, Bailie George Neilson; President, Mr. J. B. Bell; Vice-President, Mr. John McGregor; Librarian, Mr. William Caldwell; Lanternist, Mr. Kelly; Treasurer, Mr. J. Leonard Evans; Secretary, Mr. George W. Campbell; Committee, Messrs. Peter Dawson, William Pettigrew, W. S. Wilson, S. H. Wood, R. H. Hobbs, T. King, William Wilson, Baxter, Learmonth, John Brown, and A. Hamilton; Auditors, Messrs. William M'Trusty and R. Cameron. In the Record and Survey Branch the office-bearers elected were:—President, Mr. J. C. Bishop; Curator, Mr. William Caldwell; Secretary, Mr. George Campbell; Committee, Messrs. S. H. Wood, M. Philip, John Martin, and J. B. Bell.

ULSTER AMATEUR PHOTOGRAPHIC SOCIETY.—The last meeting of the winter session of this society was held in the club rooms, The Museum, College Square North, on April 10. The "Photographic News" prize slides were shown, and a series of slides made by the Hon. Sec. (T. N. Murray) from negatives taken in the Irish Bronté district (vicinity of Banbridge and Loughbrickland, Co. Down) were also exhibited. Mr. Murray suggested that members of the U.A.P.S. might send in slides to form a set of Irish sub-

jects suitable to circulate through the photographic societies in Great Britain. The Watkins pinhole lens was then shown and described. The W.P. number marked on it is 6, and this multiplied by the focal distance gives the diaphragm value. Thus at 8 in. it would be F. 48, and if the exposure is calculated with this stop by the Bee or any other meter, and the calculated time is given in minutes instead of seconds, it will be right. It can be used for wide or narrow-angle views on the same size plate.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.—At the annual general meeting of the above society Mr. J. T. French was elected President for the ensuing year. The Secretary's report showed that the society now consisted of 193 members, and several more were up for election. The financial condition of the society was a strong one, as after writing off some heavy expenses for screens, tables, etc., in connection with the 1904 exhibition the actual cash in hand amounted to £97. Excursions had been better attended than for some years previously, and the portfolio section was flourishing. The Secretary (Mr. H. Creighton Beckett) and the Committee are to be congratulated on the year's working.

HULL PHOTOGRAPHIC SOCIETY.—The twenty-second annual general meeting of this society was held in the society's rooms, Grey Street, Hull, on Thursday, April 8. The Secretary's report showed that not only had a very satisfactory year been passed, but that the financial condition of the society was quite sound. A good summer syllabus has been arranged. The officers for the ensuing year are as follows:—President, G. F. Bristow; Vice-Presidents, W. T. Parrish and Rev. C. D. Stewart; Treasurer, D. L. Cockcroft; Hon. Solicitor, R. E. Johnson; Hon. Lanternists, W. Dalton and T. Frazer; Hon. Editor and Librarian, W. Gilleard, 11, Clumber Street; Hon. Curator of Enlarging Apparatus, H. Strong; Hon. Secretary, A. E. Hindson, 104, Blenheim Street; Council, F. Atkins, son, Hewart Fraser, F. Woolions, J. T. Dyson, and R. Clark.

EXHIBITION AT CHESTER.—The Sheriff of Chester (Dr. Mann) opened on Thursday evening last the second annual exhibition of the Photographic Section of the Chester Society of Natural Science in the Art Room of the Grosvenor Museum, Chester.

CROYDON CAMERA CLUB.—Mr. Manly demonstrated the "Ozotype" process to the members of this club on April 12. In addition to developing several carbon prints of first-rate quality, Mr. Manly showed and explained the method of working "Gum Ozotype." This possesses the usual flexibility, together with a range of gradation, and capacity for rendering detail, far beyond what is usually seen.

ACTON PHOTOGRAPHIC SOCIETY.—On April 12 a demonstration of the carbon process by single and double transfer was given by Mr. H. G. Green to the members of this society. The president, Mr. H. E. Burn, in his concluding address of the session, gave an interesting sketch of the origin and progress of commercial photography. The first of the summer outings will take place early in May—to Uxbridge.

DUNDEE AND EAST OF SCOTLAND PHOTOGRAPHIC ASSOCIATION.—At the general meeting of this association, Mr. J. H. Williamson, Kirkcaldy, gave a demonstration of the Blake Smith iodine toning process. Among the prints used in the demonstration was a 15 by 12 print on Royal Bromide. This had been toned in a hypo-alum bath, but the colour not being satisfactory, a fresh bath had been made up, and the print left in it for a week, the bath being occasionally shaken up during that time. The print was found to have gone back to its original black colour. This print was then bleached at the meeting in the iodine solution, and passed direct into the sulphide bath, the result being a very fine brown colour. Mr. Macdougald, the president, exhibited some experiments he had made in a printing process, which was an adaptation of Woodburytype. He coated a glass plate

thickly with a solution of bichromated gelatine, which, when dry, was printed under a transparency. The plate was then placed in cold water, the result being that the parts unacted on by light began to swell up, thus giving an image in relief. While wet, a mixture of plaster of Paris and water is poured on the plate and spread over it with a camel-hair brush very gently to remove any air-bells which may have formed. When the cast had set, it was lifted off the gelatine relief, and others could be made. When the cast was dry, the face was dipped into melted beeswax, and then polished with oil. To make a print from the cast, a weak solution of gelatine and water was made, to which a little suitable colour from a tube of moist water-colour was added. This solution is melted and a little spread on a piece of paper, the plaster cast is then pressed on the inked paper, and left with a weight on it till the gelatinised ink has set. The first results were very promising, and should furnish a field for further experiments.

LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION.—On April 13, Mr. G. E. Rawlins demonstrated "The Oil Process" to a large number of the members. The flexibility of this process was shown by the demonstrator, who removed completely certain parts of the picture, and then as easily replaced the obliterated portions. This was done over and over again without leaving any traces. Prepared paper is now on the market, and can be obtained from Messrs. Elliott and Sons, Barnet; this paper, to be made ready for use, has merely to be dipped into a solution of one part of saturated solution of bichromate of potassium, with one part of water, and allowed to dry. This formula for sensitising the paper is the only "formula" in the entire process. Mr. Rawlins claimed for the process this, "That it allows a worker to stamp his own personality on the resulting prints to an extent which is impossible with any other process, not even excepting gum-bichromate."

Commercial & Legal Intelligence

At the offices of the Official Receiver for Leeds (Mr. John Bowling) yesterday a meeting was held of the creditors of Cecil Montague Stafford, residing at 5, Nassau Place, Leopold Street, Leeds, and carrying on business as a photographer under the style of Cawkwell and Stafford at 2, Commercial Street, Leeds. His liabilities were stated to be £634, and assets nil. The debtor attributed his failure to excessive price of businesses purchased and bad trade.

At the Birmingham Bankruptcy Court, last week, Marcus Bennett, formerly residing at 12, John Bright Street, Birmingham, appeared for his public examination. The statement of affairs filed by the debtor disclosed liabilities amounting to £160, and a deficiency of £135. The debtor had devoted himself to the business of a travelling photographer, visiting barracks and military depots.

A FOUR YEARS' OLD CLAIM.—At the Burton County Court on April 12, before his honour Judge Lindley, an action was brought by George Renwick, photographer, of Station Street, to recover the sum of £2 3s. from Arthur Holmes for a number of group photographs taken four years ago. It was contended in defence that the proofs submitted were unsatisfactory, and that orders had been given not to proceed. This was denied, but the judge said he did not think the completed order for 12 was given, and there would therefore be judgment for 10s., without costs.

At the Manchester County Court on Monday of last week an action was heard in which Messrs. E. Hulton and Co., Ltd., newspaper proprietors, sought to recover 10 guineas for breach of contract from the Palatine Press, Ltd., of Manchester. Two portraits

had appeared in one of the plaintiff's newspapers, and the zincograph blocks, from which they were printed, were afterwards sold to Mr. Brettelle, of the Palatine Press Co., on the understanding, so the plaintiffs alleged that they should not be reproduced without the permission of the photographer, who held the copyright. They were, however, reproduced in the defendants' paper, the "Stage and Field," without permission having been obtained, with the result that the photographer had obtained £10 from Messrs. Hulton for breach of contract in allowing someone else to reproduce them without his permission. The defendants stated that nothing was said to Mr. Brettelle about the necessity for obtaining the photographer's permission before making use of the blocks, and there was, therefore, no breach of contract. His Honour gave judgment for the plaintiffs for five guineas with costs.

A DEED of Assignment Sustained.—At the Manchester County Court on Friday last his Honor Judge Parry gave judgment in an application made by the Official Receiver at a sitting of the Court on April 5 for an order to set aside an assignment of property by Mr. Franz Baum, a Manchester photographer living at Bowden, to his wife. The application was dismissed with costs.

NEW COMPANIES.

CHESTER'S Agency, Limited.—Registered April 7, by Jordan and Sons, Limited, 120, Chancery Lane, W.C. Capital, £5,000 in £1 shares. Object, to take over the business of a variety and dramatic agent, photographic produce, and picture frame maker and dealer, etc., carried on by P. L. Cobé, at 13, Oxford Street, Manchester, as Chesters and Co. Registered office: 13, Oxford Street, Manchester.

PORTLAND Photographic Company, Ltd.—The above-named company has been registered with a capital of £1,000 in £1 shares. Object, to adopt an agreement for the acquisition of the business carried on by A. Coop and co-partners at 135, Regent Street, London, and to carry on the business of photographic artists in all its branches.

New styles in enlargements are set forth in a most attractive folder from Messrs. Elliott and Sons, Ltd., Barnet. The "Greuse" (bromide water-colour), the "Brunette" (toned bromide), the "Marquise" (carbon water-colour), and the "Velvetone" (finished bromide) are the distinctive names, and if the enlargements are only half as nicely turned out as the booklet describing them no photographer in the land should have cause to be ashamed of them. And we have confidence in Messrs. Elliott's consistency in such a matter. Their advertisement literature is in accord with their goods.

The prize camera for the current Austin-Edwards' Monthly Film Negative Competition has been awarded to Fred Cathery, St. Cecilia, Parkstone, Dorset, for his negative, "Study of Silver Birch and Grass."

LECTURE on Ely Cathedral.—Members of the Ipswich Camera Club, the Scientific, and the Archaeological Societies of Ipswich assembled at Ipswich Museum on Thursday evening of last week to hear a lecture by Mr. E. W. Harvey Piper, who has made the study of English cathedrals a main theme in his life, and has lectured upon them before many important societies in London and the provinces. The title of the lecture was "A Queenly Marshland Minster," and the beauties of Ely Cathedral were demonstrated in a masterly fashion.

"STAMP-PHOTO" Specialties.—Messrs. Sharp and Hitchmough have ready a new list of their varied accessories for the making and printing of photographs in stamp and midget sizes. They will send it free from 101 and 103, Dale Street, Liverpool.

Correspondence.

THE P.P.A. ASSISTANTS' CERTIFICATES.

To the Editors.

Gentlemen,—I must confess to being rather apathetic as regards the present arrangements, which seem to give for the fee merely a classified résumé of one's references.

Might I suggest that the various grades be sub-divided into first second, and third divisions and "honours," in addition to the extra first suggested by "Scot"? Also, I think there should be a "general assistant's" certificate, arranged for the convenience of both parties in advertising or applying for situations.

I give here a rough sketch of the idea as it struck me:—

ASSISTANT'S CERTIFICATE.

(Replies to questions now classified as "General.")

	Grade.	Division.
Operating—In studio	2	1
Operating—Out-door, etc.	2	2
Operating—Copying	2	2
Retouching	2	Honours.
Black and white	—	—
Printing in P.O.P.	1	3

etc., etc.

When advertising or replying to advertisements this method would supersede such expressions as "knowledge of retouching," which may mean anything or nothing, and tabulated forms might be supplied to assistants on which they could fill in the particulars of their certificates when applying for a berth. I beg to think this method would soon eliminate the "mere hangers on," and would save much time in wading through letters.

Still, until a practical examination is obtainable, I consider the fees too high. I enclose my card.—Yours faithfully,

ASSISTANT.

To the Editors.

Gentlemen,—May I plead the importance of the subject as an excuse for troubling you again?

Your correspondent "Compulsory Retired," who, as you suggest, does not express himself very lucidly, appears to have made a bullseye on a target he was not aiming at. If an unskilled labourer asks skilled bricklayer's wages, it is not likely he will get a job. The skilled bricklayer who is in want of a job, when he applies for one does not expect his mere statement to be taken that he is a skilled workman and not a labourer only, but produces credentials of some kind. It is to provide credentials of skill for the photographic assistant that the certificate system has been instituted. When an assistant is seeking a new situation he is asked, the first thing, for his references, and he has to produce them. The best of references cannot be better than our certificate, for that will embody all that his employers, present and past, can say in his favour, with the advantageous addition that an impartial body has investigated the claims made as far as they can, and has been convinced that they are substantial.

Perhaps this explanation of what a certificate means will satisfy "Pound-a-Week." May I put his question in another form and leave

it without further answer? Is any employer who considers ability rather than cheapness of labour likely to disregard the proof of ability which a certificate will afford?

Mr. J. Patterson seems to have overlooked the specification of the abilities, necessary or desirable, of candidates for the different grades, which are stated at length. It is not to be supposed that a good man is likely to be refused a certificate because he has had but little experience at some one or other of the details of photographic work enumerated. It is quite likely, for instance, that a good studio operator may never have made a "gaslight" print or have varnished a large negative, and yet be abundantly worthy of his certificate. His certificate simply will not state those, or whatever the particular items may be, among his qualifications. The examiners will judge of each candidate's capabilities in a broad-minded way. They will not expect a specialist's expertness at every branch of work pertaining to a photographic establishment, but they will expect expertness in some directions, and a general knowledge of most of the kinds of photographic work usually practised in the ordinary course of business.

We are not at all despondent of the success of the scheme because its aims have not been recognised by assistants at once. We shall be quite content to wait a few years for this recognition. Competent assistants will not fear the test, and will be gathered into our fold in a manner we are now providing.—I am, etc.,

WILLIAM GROVE, Hon. Secretary.

51, Baker Street, W.

April 17, 1905.

[See report of P.P.A. Committee meeting p. 313. —Eds., B. J. P.]

To the Editors.

Gentlemen,—With reference to Mr. Groves' statement concerning the probable alteration of the conditions of the P.P.A. assistants' certificates scheme, I regret that any change is not possible until the probationary year has passed.

He has been good enough to accept my criticism of the grading for operating assistants in the P.P.A. prospectus, and in doing so admits a weakness in its application and a failing in comprehensiveness that, in view of my previous letter, might bid fair to destroy a certain amount of the operative usefulness of the scheme. I can conceive, to some extent, the difficulties that are presented to his committee in formulating a prospectus that would apply even in broad terms to the organisation of a sadly disordered trade, but I beg to submit that unless such a scheme is, in general lines, satisfactory in comprehensive application, it must necessarily fall short of an essential standard of authoritativeness.

The first notice of the present scheme is now about two months old. There is rather less than ten months to run to the end of the trial, and, I am afraid, as matters stand, the apathy and silence that is complained of will continue in some degree until the time when some revision must take place. Meantime, it is difficult to say what may be done in remedy. Reforms come about slowly, and it would never do to try to cut and carve the P.P.A. duckling into a swan right away. Discussion would do a world of good, and the endeavour of the Association is worthy of every commendation and aid. The objects and issues of the scheme are plain and beneficial to employer and employee, and it is a pity that indifference or "dourness" has prevented the ventilation of views of master and servant alike from reaching print ere this.

In so far as we assistants are concerned, we should owe much to the Association for the step they have taken towards the solution of a great difficulty. If it is met in the right spirit, and with the support it deserves, conditions of labour in our trade would speedily fall in

line with those enjoyed in other industries. It could lead the way to the formation of an assistants' association harmonious in interests with the P.P.A. interest that would strengthen the hands of master and servant mutually, and be of great service to the trade as a trade. The possibilities within easy view are many, and all advantageous, but, even as matters stand, we have a scheme offered to us which would, were it once established and generally accepted, grade us into standards of efficiency that would give a self respect, and compel from employers a respect that could only lead to general betterment. Photography in all its latter-day applications is an important and steadily-growing art and industry, and its best interests are only served by co-operation and efficiency in the ranks of its followers.—

Yours faithfully,
April 17, 1905.

Scot.

To the Editors.

Gentlemen,—I have read your "leaders" and the correspondence on the P.P.A. certificate scheme with interest. When the draft appeared in the B.J. it seemed too vague to be taken seriously, which perhaps accounts for the lack of criticism the committee asked for. In the first place, one would think that a person who serves an apprenticeship over two years ought to be able to earn £1 a week in all conscience. His indentures would prove that without a First Grade certificate at all. Secondly, a man's character is almost as essential as his abilities, especially in a small place, and this fact the scheme cannot meet at all. Logically, an honest man does not ask for 30s. a week if he cannot earn it. Thirdly, what master would think of taking an operator under twenty-two, however good his character or abilities may be. Age seems a most important factor for or against "merit." I agree that "merit" is most essential; then why limit it to any fixed wage? "Scot" is right. There ought to be no limit. A man gains experience, his work improves, he expects more money; in other words, he does not jump from 30s. to £3—the process is gradual. I argue that these very elect "operators" are no cleverer in their sphere than we in ours—in fact, some of them were 25s. a week men once, but given apparatus and sitters whose very walk suggests a picture, they have risen to their present positions. Even we have "red-letter days" in our little lives. An angel face, perfect negatives, and a good order. What rot to limit art to a select few because others pay 30s. for midgets or something of that sort!

Leaving the scheme as it stands, may I briefly point out some omissions? There is no provision made for the man who works a studio quite alone! Would an operator's certificate (Second or Third Grade) include retouching—in fact, everything? Will female assistants be paid the same wage as males if their work merits it, for work which is looked upon more as belonging to men? Will employers be prepared to submit a fee corresponding to the one an assistant pays? Being mutual, they ought to. Will the "elect" accept the services of a person if his or her work merits it, although they may not have been apprenticed with, say, a member of the P.P.A. Committee? What difference will be made between a two, three, five, or seven years' apprenticeship? Will certificated assistants be preferred by the members of the P.P.A.?

I should like to see what other assistants think of the scheme! I thank you, Sirs, for the interest you are taking in the matter.—Yours faithfully,
R. RUSSELL.
Windsor.

To the Editors.

Gentlemen,—I have read with much interest the correspondence appearing during the past week or two in the B.J. respecting assistants' certificates, and the assurance given by Mr. Grove in your last issue regarding fees is, I think, a step in the right direction for

extending the popularity of the movement. It is hoped that now an official admission has been published that the Committee is open to consider and act upon suggestions from the assistants themselves, many assistants will come forward and express, through the columns of your valuable paper, their views on the subject.

I think that one of the objections to the certificates is the terms adopted for the description of the three different classes. These appear to be somewhat unfortunate. The construction I have heard put upon "First Grade," "Second Grade," and "Third Grade" has been "first-rate," "second-rate," and "third-rate"—a very natural conclusion to arrive at.

If the employer has not carefully studied the matter, or knows nothing of the P.P.A., the production of a "Third Grade" certificate is likely to be prejudicial and stamp the applicant as "third-rate."

That this is not really the case is, of course, obvious to anyone who has seen the qualifications necessary for obtaining the certificates, but unfortunately this knowledge is not so universal among photographers as it might be.

Call the certificates "A," "B," and "C," or "First Class," "High Grade," and "Special," or some other terms that will not upset the tender susceptibilities of the sensitive assistants, jealous of their own abilities, or mislead the employer, and another step in the right direction will have been accomplished.—Yours faithfully,

PEMBURY WARD.

Birmingham, April 15.

MAKERS' FORMULÆ.

To the Editors.

Gentlemen,—Probably the subject of this complaint is not new to your pages, but I cannot recall anything within recent years bearing on the subject, and I should like to have the opinions of others on the points that I now raise.

Let me first premise that Messrs. Hurter and Driffield adopted as their standard pyro soda developer, one which was very simple, and as this has been accepted by nearly all plate makers as a standard, why do they give in the working instructions for their plates such complicated formulæ as they do? For instance, we are told to make up a stock solution of pyro, which is not a 10 per cent. solution, and then dilute part of this with water and mix with the alkali. If I have not got this particular stock solution made up, I have to sit down with pencil and paper and calculate out, as well as I can, how many grains of pyro the plate maker thinks the best for his plates.

Some makers give "water to x oz.," others merely say "water, x oz.," and the result is hard thoughts, if not hard words. Let me take two formulæ, hypothetical ones, because I am attacking no one in particular:—

A	
Pyro	1 oz.
Sodium sulphite	4 oz.
Citric acid	50 gr.
Water to	10 oz.
B.	
Pyro	1 oz.
Sodium sulphite	4 oz.
Citric acid	30 gr.
Water	10 oz.

What is the total volume of B, and how many grains of pyro are contained in an ounce?

Is A a 10 per cent. solution, or is "pyro 1 oz." = 437.5 grains.

Why cannot makers give us a typical formula, such as the following?—"A developer suitable for these plates is one containing 3 grains of pyro to the ounce."

What is a 10 per cent. solution?

You sometimes give metric and English weights and measures together (see the B.J.A.); how do you get at the results given? Will you, or some one kindly tell me, and to bring things to a focus I will take a concrete example. Here is a particular formula, which, according to the International Congress of Photography, means that the total bulk must measure 1000 ccs. What is the translation if I want to make up a pint?

Hypo	400 g.
Sodium chloride	20 g.
Lead acetate	10 g.
Gold chloride (1 p. c. sol.)	100 ccs.
Water	1000 ccs.

I hope some one will answer me.—Yours faithfully,

ARTHUR PEAKE.

London, E.C

FERROTYPE SLOT-MACHINES.

To the Editors.

Gentlemen,—Having all kinds of automatic machines along the Reef, I wish to find out the makers of the automatic ferrotype machines to work with a coin; the machines should be of iron to stand the weather, and operate with a threepenny piece.

I should like to have the price of new or secondhand, the price of plates, and all details about the apparatus.—Yours faithfully,

VERNON G. HOOREY.

Opposite Railway Station,

Mayfair, Johannesburg, S.A.

March 27, 1905.

[Although automatic and semi-automatic ferrotype slot-machines are made, it is not within our knowledge that they are at present on the market.—Eds., B.J.P.]

THE INVENTOR OF GUM.

To the Editors.

Gentlemen,—I note in your last you raise the question once more as to my father inventing the gum bichromate process of printing direct on paper. It would, I fear, take up too much time and space to discuss that at length at this date. There is one fact that is rather stubborn, that though theories had been advanced, no proof was ever given of prints so produced until my father did them in 1858. In those early days, no sooner had any one an idea than he rushed off to the patent office to protect it, and Mr. Sutton at that date was inclined to think "that Poitevin patented an idea rather than a process he had actually tried and found to answer. Besides, his patent includes the experiment made by Mr. Mungo Ponton in 1838 with bichromate of potass. and Saxony blue." My personal impression is that both he and my father were working in this direction quite independently and unknown to the other—the one more in the direction of press printing, the other direct on paper. Let us recognise both as co-workers towards that end which permits us now to have photographs of our friends and copies of our great Masters in a form that is enduring. Both of them were recognised by the French Society, and received medals under the Duc de Luyne's prize commission. I do not wish to say a word to detract from the work M. Poitevin did in his special direction.

W. POUNCEY.

Dorchester, April 11, 1905.

[Mr. Pouncey also sends us extracts from correspondence proving that at the time of the 1898 Exhibition of the Royal Photographic Society at the Crystal Palace a reproduction of an oil painting by his late father's process was delivered by mistake to an exhibition of oil paintings also being held at the Palace, an accidental proof of the facsimile effects obtained by the process.—Eds., B.J.P.]

Answers to Correspondents.

- * * All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.
- * * Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- * * Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.
- * * For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington-street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED :—

- R. C. E. Nissen, Tudor Chambers, Church Street, Pretoria, South Africa. Two Photographs of the Cullinan Diamond.
- W. H. Brison, 65, Thompson Street, Barry Dock, Glamorganshire. Photograph of the Post Office, Barry Dock.
- J. Dunsdale, 12, New Station Street, Leeds. Photograph entitled, "The Quickstep Train in Europe."
- G. Cross, 173, Lord Street, Southport. Two Photographs of the Southport Cleveley.
- C. J. Atkinson, Beech Mount, Marple, Cheshire. Photograph of the Rev. Reginald S. Adams, M.A., Vicar of Marple.
- E. R. Yerbury, 1, Hanover Street, Edinburgh. Photograph Study, "Springtime."

GELATINE AND SPIRIT.—In some experiments I have in hand I wish to treat a gelatine film with a strong spirit, but do not want it to penetrate the film, as it is necessary that it should not soak it. Is there any method by which I can prevent it?—A. R.

Gelatine is insoluble in alcohol, and will not absorb it, therefore there is no need to treat it in any way. The stronger the spirit—and we presume by this alcohol is meant—the less likely is it to be absorbed.

STRIPPING NEGATIVES.—I have some negatives and want to transfer the films to another glass. Would you kindly inform me how it can be done?—POSITIVE.

A very good method is that of Middleton and Holcroft described in "The Figures, Facts, and Formulae of Photography," as follows:—Stock Solution: Methylated spirit 25 oz.; water, 1 oz.; glycerine, 1 oz. Cut through film all round about $\frac{1}{8}$ in. from edge and set plate level. Pour on stock solution plus hydrofluoric acid—6 to 30 drops per oz. Spread with a bit of paper and remove strips when loose—i.e., in four to six minutes. Next see that main film is loose by running a white silk thread stretched on a cane bow underneath. The turn off solution and twice pour over plain stock solution (without acid). Coat glass plate with thin gum solution so as to get a film so thin as to show only on applying a moist finger to one corner. Apply a "paraffine sheet" (see below) to the negative, and squeegee lightly. Remove film and sheet together by inserting a knife under the former, and apply the gummed plate after flowing with stock solution. Lightly squeegee and remove the sheet. The "paraffine sheets" are made by soaking thin paper, not highly sized, in hot melted paraffine wax for half an hour or so; they are better than paper, as they do not buckle.

JAMES HORNER.—We believe the firm is no longer in existence. Any practical optician, such as Perken and Co., Hatton Garden, London, W., would do the job for you.

MARK MITCHELL AND CO.—Harold Hood and Co., St. Bride Works, Middlesborough, Percy Lund, Humphries and Co., The Country Press, Bradford, are two such firms.

POST-CARD FRAMES.—The Makers are J. and A. Wilkinson, 6, St. Oswald Street, London, W.C.

H. A.—We do not know of a firm which is likely to take up the business, you making the prints. Firms such as the Autotype Co. might consider the issue of prints made by themselves. The royalty on sales is a matter for arrangement.

ARTIFICIAL LIGHT.—I am about to open another photo. business, and the only shop that seems in a suitable position, and that will suit in other respects, has not any room for studio. There is, however, a good room, big enough for such. What I want to learn is: Would it be worth while having this room fitted up as a studio and using *artificial light only*, and if so, what light would you recommend? My work is of the "middle-class" quality. I should be glad of your advice on this, as I would sooner wait for another suitable place if I thought this would not answer satisfactorily. I might say I have used the electric light with fair results after daylight has gone.—**ARCADE.**

There are several good gas and magnesium lights, and, except for very large groups, it will not be necessary to pay a heavy price for a suitable installation. You will see announcements of apparatus in our advertisement pages. We think you will be wise to fit up with one or other of these lamps.

TRouble IN CARBON PRINTING.—In carbon printing I have been induced to purchase some of —'s tissue. Used in the same way as Autotype and Illingworth's, I get very different results. I sensitise myself, and, while with the three makes of tissue, sensitised, dried, printed, and developed, under exactly the same conditions. I obtain pure whites with Illingworth's and Autotype; with —'s I am always troubled with fogged whites, an effect equivalent to slightly tinting the paper before printing. Is this characteristic of —'s tissue, or does that make of tissue require a different sensitising formula? There being no printed instructions sent out with the tissue, I am puzzled as to the reason.—**SENLIN.**

We have used the foreign tissue named, and have not experienced the trouble mentioned, though it has been dealt with in precisely the same way as English tissues have been. We suspect that in the drying the tissue has been exposed to some noxious fumes, such as those from burning gas, for example. Under such conditions any make of tissue would suffer. Why not stick to the tissues you name, as you say you meet with no trouble with them?

STONE.—If you consult the advertisement pages of the B.J. you will see the names of one or two firms that do this work cheaply and well.

COPYRIGHT.—A friend of mine, an American residing in Boston, U.S.A., wants a photograph he has taken in America copyrighted here. How can he proceed? I presume that once the photograph is copyrighted here no one would be permitted to copy the same photograph if they received one from U.S.A.?—**BOSTON.**

Unless your friend is a British subject he cannot obtain copyright here. See the letter from the Copyright Union in our last issue.

FINNEY AND OTHERS.—In our next.

RETOUCHING AND OPERATING.—I am sending some samples of my work, and would be obliged to you for an opinion both on the retouching and the operating. The time I took to do the retouching I have marked. Could you also give me an idea of the salary such work would command?—**ESSEX.**

(1) Your retouching is fair only, and your work generally calls for much better modelling. The freckled faces are not near fine enough in the finishing, and you should double-work them if you cannot get better results on the one surface. Use a good retouching medium on the film; work out softly the main defects, and then varnish with a good hard negative varnish; when cool, again mediumise and retouch to a finish. You must look to the blending of your touches more, and try to get fineness without so much effort. The time taken on each sample sent is excessive. The large half-retouched face is about your best effort, but is too formal and hard in the touch, and the high lights should have been considerably increased. Follow the correct grain of the skin more, and do not retouch on the wrong slant. Three hours should have seen the whole face finished. (2) The operating, like the retouching, is fair only. One or two of the subjects would have been better had they received a longer exposure, they would then not have been so crude as they are. (3) Your work as operator and retoucher should command about 35s. to £2 per week, but it is always difficult to estimate probable wages. What a man wants and what he may get depends greatly upon where he applies and his own personality.

RETOUCHING.—I should be glad if you would criticise my retouching, and state what I ought to receive for my work (done at home). I enclose five photographs.—**A. T. M.**

(1) Your retouching is of the very poorest quality, and is not properly smoothed over, without taking into account an utter want of modelling and gradation of tones. With regard to the preservation of the likeness, it is impossible for us to judge, inasmuch that no proofs before retouching are sent. You are evidently a beginner, or of very short experience, and your work is of little commercial value—except to those as inexperienced as yourself. We are apparently cruel only to be kind, and strongly advise you to at once take lessons from an expert teacher of retouching, under whose guidance you might in a few months entirely reverse our verdict upon your work. Our advertisement columns usually name several teachers of this art. (2) Working at home you may get orders from local amateurs, and even professionals, at low rates, but you should certainly aim higher before expecting or deserving success.

ENLARGING.—(1) From quarter-plate negatives I want to make rough-and-ready enlargements on drawing paper 24 by 20 in. for the purpose of finishing in water colours. I want the enlargement simply as a sketch and guide for the painting; and I desire to know of the best and easiest method of preparing surface of paper for producing such a sketch apart from the gelatine-bromide process. Kindly observe that I require neither fine results nor the greatest rapidity, as the enlargement is only a means to an end, and I can always use good daylight for the work. I believe enlargements on paper were made before the introduction of the present rapid trade bromide, etc., paper. Will you kindly give me particulars of that ancient process, which our forefathers seem to have been able to carry through from beginning to end in their own home. Perhaps it would prove satisfactory for my purpose mentioned above.—**FRED.**

The old calotype process should suit our querist, and the following is a brief synopsis of it: Immerse paper in the following for one hour: potassium iodide, 1,000gr.; potassium bromide, 300 gr.; distilled water, 40 oz.; add enough iodine to give a dark claret colour. When the sheets are dry, sensi-

tise by floating on silver nitrate $2\frac{1}{2}$ oz., glacial acetic acid $2\frac{1}{2}$ oz., distilled water 40 oz., until the surface is pure yellow, then allow to remain for one minute, lift, and immerse for three minutes in distilled water, and dry. After exposure, develop with: gallic acid 200 gr., distilled water 40 oz., to every 5 oz. of which is added: nitrate of silver 30 gr., glacial acetic acid $\frac{3}{4}$ dr., distilled water 1 oz., then well wash and fix.

NATURAL COLOUR PHOTOGRAPHY.—Can you please tell me of any works on "Natural Colour Photography" and the publishers?
—J. C. R.

The following is a list of the books, placed in order of merit:—"Three-Colour Photography," by von Hübl, published by Penrose and Co., price 7s. 6d.; "Photography in Colours," by Bolas, Tallent and Senior, Marion and Co., 5s.; "Colour Photography," Photo-Miniature series, Dawbarn and Ward, 6d.; "Colour Photography," A. E. Smith, Hazell, Watson, and Viney, 1s.

SENSITISING POST-CARDS.—Could you give me instructions, or refer me to any book, for method of sensitising post-cards with glossy surface preferred?—H. WILLIAMS.

Formulae for gelatino-chloride emulsions will be found in the "British Journal Almanac" for any year during the last ten, and any of these may be used. It would be as well to point out that unless the cards are bought in the sheet the labour involved in coating each one separately, and the chance of spoils, is enormous. Further, unless the cards are made of good stuff they will spoil any sensitising solution. Considering the price that these can be obtained wholesale it is not worth while to prepare them at home, and it certainly is not cheaper.

CARBON TISSUE.—(a) Would you please inform me if it is possible to get a formulae for making carbon tissue. I am doing a little experimenting, and am anxious to make a little tissue. (b) Is it possible to prevent a carbon print from peeling when exposed to heat?—C. D.

(a) Full instructions will be found in "A Practical Guide to Photographic and Photomechanical Printing Processes," published by Marion and Co., price 4s. (b) We do not quite understand from what the print peels; if the surface to which it is applied has been properly prepared by a chrome-gelatine substratum it will not strip.

RESIDUES.—Would you kindly say if the usual iron solution, as used for precipitating the gold in ordinary spent toning baths, is equally efficacious in a combined bath, where prints have received no washing previous to immersion?—BRIDGE.

Yes, but a good deal of other matter, carbonate and sulphide of iron, is thrown down; the precipitate must be digested in aqua-regia, and the gold, in the resulting diluted and slightly acid solution, again precipitated by ferrous sulphate.

MANCHESTER MAN.—Search can be made at Stationers' Hall (Ludgate Hill, London, E.C.) on payment of a small fee.

BOOK ON INTENSIFICATION.—Is there any book devoted entirely to the intensification and reduction of the negative? If so, will you please give me name and price?—L. B.

"Finishing the Negative," published by Messrs. Dawbarn and Ward, price 2s. 6d.

LAINER'S REDUCER.—Have you ever heard of a reducer of this name? I do not find it mentioned in any of the text books; but a

customer has asked me to make it up for him, so I shall be glad if you can tell me of what it is made, and the formula.—LANCASTER.

Hypo solution (1 in 4), 20 ounces; potass iodide, 90 grains. The solution acts extremely slowly, so slowly as to render it of very little practical use. You had better tell your client to use very weak Farmer's reducer.

STAIN REMOVER.—I read some time ago, but where I cannot recollect, that hypochlorite of soda is a good chemical to use for taking the stain out of a negative. Can you tell me where I can get this chemical, as my chemist is not able to supply it?—MARCHANT.

You had best prepare a solution of the hypochlorite yourself from bleaching powder, as the hypochlorite itself does not keep at all well. Shake up one part of bleaching powder with $1\frac{1}{2}$ parts of soda carbonate cryst., previously dissolved in water, and, after a little time, filter. Shake up again with a little water, and again filter. Repeat a third time, and you will now have a fairly strong solution of sodium hypochlorite. It should be alkaline. If it is made acid with a drop or two of hydrochloric acid, it is a still more active anti-stain, but it is then very liable to remove the silver image also.

SURVEY and Record of Surrey.—The Report of the Council of the Photographic Survey and Record of Surrey has been sent us, and, as already mentioned in our note on the annual meeting, presided over by Viscount Midleton, a satisfactory result for the past year is shown. A total of 1,272 prints have been received up to date. The architectural prints number 455, of which 367 represent churches and church monuments. Excluding the Metropolitan area and the more populous districts of Surrey, the portion of the county to the east of Reigate may be said to have been thoroughly surveyed as regards its churches. It is remarkable, considering the number of workers in the town, that the survey and record of Croydon is far from complete.

PRESENTATION to a Photographer.—At Clarence House, Hereford, on Wednesday evening, April 12, Mr. A. R. Osborne, who is leaving Hereford, was made the recipient of a handsome present from the members of the Herefordshire Photographic Society as a slight recognition of the many valuable services rendered by him to the society and of the great esteem in which he is held personally. The gift consisted of a combination French cylinder clock, barometer, thermometer, and compass, on a stand, with glass cover. Mr. Osborne is going to manage a photographic depot for Mr. Ralph Cuthbert at Huddersfield.

**** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

EX CATHEDRA.

The Amateur Question again. The perennial query as to what constitutes an amateur photographer or rather, by what means does he relinquish a right to that appellation, has been exercising the minds of the committee of the recent Art and Industry Exhibition at Eastbourne. It appears that a well-known local amateur photographer, and a Town Councillor to boot, was disqualified in the amateur section of the exhibition on the ground that he was a professional, because he had received fees for the reproduction of some of his photographs in the illustrated press. Apart from the fact that the Town Councillor would have been very stupid if he had not received fees for his pictures, we wonder what the effect would be of this decision on the part of the committee was made in arbitrary law at all exhibitions. What a flutter among the gentle amateurs of England it would cause, to be sure. How many proficient amateur photographers are there in this country who have not at one time or another sent a print or two to an illustrated paper and pocketed the resultant half-guineas without a qualm? Not a great number we venture to think, and by amateur we mean the individual who regards photography as a hobby, not as a business.

Copyright in South Africa. Our South African colonies stand in particular need of definite legislation as to copyright, for, obscure as artistic copyright law is in many parts of the Empire, in South Africa its character has been nebulous up to the point of invisibility, and for practical purposes no protection could be obtained. However, a Bill is to be brought before the Cape Parliament this session, in which copyright in "works of art" is to be dealt with, "works of

art" including photographs. The chief provision of the Bill appears to be that the duration of copyright in photographs is thirty years after the end of the year in which they or any copies may have been first offered for sale or otherwise exposed or advertised as purchasable by the public. To paintings and sculpture it is proposed to grant copyright for the lifetime of the author and thirty years after his death. Another provision is that when a work of art is sold the copyright becomes the purchaser's, unless it is expressly reserved in writing to the author or vendor. We do not know whether the proposed Bill is put forward as applying to the whole of British South Africa, but it is to be hoped that it is, for the present doubt and confusion should then be removed. Cape Colony, it would seem, can obtain no protection for artistic works from the Copyright Act (South African) of 1873, though designs can obtain copyright, under an Act of 1894, for five years from registration. There is, or was, no copyright law in the Orange River Colony, and in the Transvaal the Act of 1887 is cumbrous and costly, as a correspondent pointed out in our columns some few weeks ago.

Lines of Drapery.

One of the difficulties we have often noticed in handling portraits of ladies —three-quarter and full lengths more particularly—is the breaking of many of the flowing lines of draperies by the arm of a chair or the end of a settee. Of course, the fashion in skirts largely affects this matter, it being much easier to get good, flowing curves with a full than with a tight skirt. After a few years' experience in the studio, too, the operator knows pretty well the sort of chair to select; but a capital plan is to get the sitter to sit on the edge of the chair or other seat as much as possible. By this means the lines are not nearly so broken and in very few cases, if the thing is done properly, is it in the slightest degree apparent that such a dodge has been resorted to. Another point of advantage is that with stuffed-over furniture, the centre of the seat is so sprung and stuffed that it is a good deal lower than the edge when being sat upon. This tends to make the figure appear dumpy, and the dumpiness is accentuated by the broken curves of the dress. The sitter may not feel quite so comfortable as if sitting well into the chair, but we believe the final effect will amply compensate for any little disadvantage of this kind.

Dr. Hartmann's Method of Lens Testing. Mr. S. D. Chalmers' paper, which appears on another page, will, doubtless, receive much attention from all interested in optics. His description of the manner of applying the Hartmann method for the purpose of accurately determining and critically measuring the aberration of a lens requires no amplification, but it may

be useful to point out that this system of testing also affords an invaluable means of studying the aberrations. With a simple reading lens fitted with a few cardboard discs perforated in zones and radii, and the aid of a small source of light, the structure of an aberrated light-pencil can be studied, and, what is much more, *understood*, with facility. An hour's work with this simple outfit will teach the student more about the structure of a light-pencil than many hours spent over text-books, with their wholly inadequate diagrams, and too often imperfect, and even incorrect, explanations. The image projected may be received on a card, and, if each point is carefully recorded and perforated, the card and its corresponding disc may afterwards be mounted in the proper relative positions and the corresponding perforations connected by threads. The result is a permanent model, and from personal knowledge we can say that such practice may be of the utmost value to students. It will be remembered that a model constructed in this way was shown by Prof. Sylvanus Thompson in his Traill Taylor Memorial Lecture of 1902. The system of demonstration adopted by him was practically the Hartmann method on a big scale.

* * *

Dr. Zschohke's Method.

The second method of testing described by Mr. Chalmers, and introduced by Dr. Zschohke in 1896, is also an interesting one. It may fairly be described as a method analogous to that introduced by M. Baille-Lemaire in 1892. In the earlier method, an inclined plane object-diagram is photographed on a normally situated plate; in the later one a normally situated diagram is photographed on an inclined plate. The arrangement in the earlier method conforms more closely to the usual disposition of subject and plate, but it appears to have been superseded by the Zschohke method, probably because with the latter it is easier to trace the lines and curves of equal definition. A comparative study of the two methods should be interesting. Both have the defect of recording the behaviour of the lens upon an object at a nearer distance than that at which the lens will usually be required to work, but the Hartmann method is, of course, free from this defect.

* * *

Poisoning by Cyanide of Potassium.

It is not often at the present time that we hear of poisoning by cyanide of potassium, but three deaths from it have occurred within the past few weeks. Last week an inquest was held on the body of a lady of title who had, during temporary insanity, swallowed some of the poison. The husband, in his evidence at the inquest, said that he had bought the cyanide quite thirty years ago for photographic purposes, and the bottle had never been opened, but the lady knew of its poisonous nature. It had always been kept in a locked-up cupboard, but on this occasion the key had inadvertently been left in the lock, and provided the disastrous opportunity. In the days of the wet collodion process, when cyanide of potassium was the almost universal fixing agent, poisoning by it not infrequently happened, either by accident or design. Of late years, when death has occurred from this salt it has generally been obtained in connection with electro-plating, gilding, or metallurgy, in which work it is largely employed. It may be remembered that the man Sarti, charged with receiving stolen ingots of silver, poisoned himself with cyanide of potassium, as did also Whitaker Wright after his conviction. Unfortunately, for this poison no successful antidote is known; probably the best thing, if administered at once, would be a salt of iron. But the action of the poison, like that of hydrocyanic acid, is so rapid, especially if swallowed on an empty stomach, that

no antidote, unless it were administered immediately, we fear, would be of any avail. An iron salt would combine with the cyanide, and forming a possibly inert insoluble cyanide of iron; but to be of real use, as we have just said, an antidote must be taken immediately after the poison is swallowed.

* * *

Expression in Portraits.

The question as to whether a long or a short exposure is better for the securing of characteristic expression is one which has often been discussed, and it is perhaps inevitable that no definite decision has been arrived at, either for general use, or for the constant practice of any individual worker. The fact, of course, is that each sitter requires individual and sympathetic handling, and sympathetic handling means in some cases a very brief exposure of which the sitter is unaware, and in others the more prolonged exposure which produces a blending of several slightly varying expressions. With restless children, and with very animated sitters of larger growth, the contrast between the usual state of conversational animation and the collapse to "flatness" when asked to "keep still" for the exposure, is so great, that no method is really practical, except a rapid plate and the silent shutter inside the camera. We are inclined to think, however, that more phlegmatic sitters, whose expression is fairly equable, are better photographed with the longer exposures. Any very marked or distinct expression is unusual, and this is what is most likely to be obtained with a rapid exposure, particularly if a thoughtless operator endeavours to "brighten up" such a sitter with some of the infelicitous remarks sometimes used.

* * *

More Picturesque Spots on the Thames Threatened.

One by one the beauty spots on the Thames, of which there are none too many, are threatened with extinction. Most who are familiar with the picturesque little islands at Kingston, known as Stevens' Aits, will regret to learn that the stream, for want of proper care, is gradually washing them away. The Kingston Corporation, it appears, has written to the Thames Conservancy offering to take the sole responsibility for the future condition of the Aits if the latter would contribute one-half the expense of camp-shedding them. The cold reply of the Conservancy is that it is prepared to give a twenty-one years' lease to the Corporation, at a nominal rent of one pound per annum, on condition that it protects the islands at its own expense, and preserves them for the free use of the public as heretofore. To this the Kingston Corporation demurs, in face of the fact that the Aits are more largely used by strangers than they are by the residents of Kingston. Therefore, it considers that the Conservancy's terms are unreasonable, and it is very doubtful if they will be accepted. The deadlock is a matter for regret by every lover of the Thames, and, meanwhile, for every month the settlement stands in abeyance, the islands are steadily being removed.

In a recent criticism on an exhibition of miniatures, the "Times" says: "'Killed by collodion' was all that could be said for a good many years of the art of miniature painting in England. Not that miniature painters ever wholly ceased out of the land, but when the public came to prefer the apparently infallible results, and the prices, of photography, the descendants of Cooper and Cosway found their occupation practically gone. It is to be feared, too, that in their struggles for life some of them actually enlisted the services of photography, an insidious handmaid, and incurred the suspicion that their work was not much better, after all, than a coloured photograph."

PRINTING PROCESSES. — I.

PLAIN OR SALTED PAPER.

WITHOUT entering into historical details, it may be pointed out that this is the oldest of all printing-out processes, and, though it has fallen into considerable disuse, it is still looked upon with favour by many, and deserves more attention from the ever-increasing army of those who prefer matt or plain surfaces. It possesses, too, this feature, that one can sensitise almost any paper, thick or thin, smooth, rough, or extra rough nor is there any difficulty, provided ordinary care and cleanliness be observed.

There is, however, one point which should not be overlooked, and that is that plain paper is not suitable for every kind of negative; a thin, flat negative gives nothing but a flat sunken-in print, whilst a harsh negative causes the shadows to block up too much; this not being the case, or so apparent, when a paper with a glaze, such as albumen, P.O.P., or collodio-chloride is used. On the other hand, as the paper is prepared at home, considerable modification may be obtained by variation of the salting solution, as will be seen later. Another advantage which plain paper possesses is that it so readily gives the sepia and warm blacks, which are at the present time so much in favour for large prints.

As regards the choice of paper, the surface will naturally determine this to some extent, but it is important to obtain paper that is free from wood-pulp, as this very quickly yellows on exposure to light. For smooth surfaces, the well-known raw papers of Rives and Saxe may be used, and for the rougher surfaces any good drawing paper; as most of the drawing papers are gelatine-sized, it is important that they should not be kept long after sensitising and before printing, as otherwise the free silver nitrate can be partially decomposed, and a permanent yellowness be the result. Some years ago one well-known worker used to invariably soak such paper in successive baths of hot water till the whole of the size was removed, and then resize; this, however, is hardly necessary if the paper is used soon after sensitising.

Whilst the beauty of a salted paper print lies in the absence of glaze, it is essential that the image should be kept as much as possible on the surface of the paper, and therefore a size is generally used; but if a preliminary test is made with a small piece of paper, and the image is found to lie sufficiently on the surface, the sizing may be omitted. As, however, the use of a size does not impart a gloss, and keeps the image on the surface, it is as well to always use one.

Gelatine has been frequently recommended, but it will not give the best results if platinum is used for toning, as it nearly always has a yellowing effect. Of course, if toned papers are used, this is not of much moment.

The best substances for sizing are undoubtedly arrowroot and agar-agar. The latter is not so easy of application as the former, but is preferable for extremely rough and absorbent papers, as it remains absolutely on the surface. Taking all things into consideration, arrowroot is to be preferred, though an excellent size is to be made with a mixture of albumen and arrowroot, as suggested by Baron von Hübl, and such paper has a somewhat greater latitude in the character of negative required than a plain arrowroot paper.

It has often been suggested that the paper should be floated on the sizing and sensitising solutions, but we consider it far preferable, though possibly a little more trouble, to use the brushing-on method, and it is this which we shall proceed to describe.

The actual material required, beyond the chemicals, is small. A drawing board or sheet of plate glass of convenient size, two brushes for sizing, and two for sensitising, a wooden clip or two, and the outfit is complete, except, of course, the ordinary dark-room appliances, measures, etc. First as regards the brushes. Two should be long-haired, flat sable brushes, the hairs at least one and a half inches long and not bound with metal. Two may be short-haired, stiffer brushes, round, and about one inch in length. Hog-hair stippling brushes are useful. One of each must be kept for sizing and for silvering and those for the latter work should be immediately after use well washed in very weak ammonia water and afterwards in clean water till they are absolutely clean.

In order to keep the paper flat, a drawing-board may be used, and the paper pinned down to it; but there is one danger in this method and that is the metal of the pins may cause marks if accidentally touched with the silver solution. To prevent this is fairly easy; all that one requires is the lid of a small pill-box, place this face downwards on the paper and drive the drawing-pin through the middle; the edge of the lid absolutely prevents any actual contact with the pin. Another objection to the use of the board is that it is impossible to size and sensitise right up to the edge evenly without touching the board, and this may cause stains on the back of the paper in subsequent use. Then, again, when the paper is wetted, it at once begins to cockle, and unless stretched, there is a chance of unequal application of the solutions. The remedies are obvious. First, cut the paper larger than is required, and sacrifice half an inch all round; and secondly, as soon as the paper is damp, remove the pins from two opposite corners and again strain the paper and again fasten down.

Another very good plan to keep the paper flat is to use plate glass, and to cut the paper an inch or two longer and wider than the sheet of glass and pin it down at one end, slip the glass underneath and then strain it down and pin down at the other end. One thus has a raised surface to work on, and after damping, the paper can be readily strained taut by lifting one end and pulling.

The actual size is most conveniently combined with the salting solution, but before we proceed to give actual working formulæ, it may be as well to point out that modification of results may be obtained by variation of the salting solution. It is customary to use not only silver chloride, but also an organic salt of silver, and the most convenient is the citrate. The use of the latter lowers the sensitiveness of the paper, and also, within certain limits, affects the gradation, but the most important point is the amount of the chloride used. If but little chloride is used, it is impossible to obtain rich juicy shadows, and the lower the proportion of chloride to the surface, not to the citrate, the weaker and flatter the print, and obviously vice versâ. Then if to the above-named salts we add silver chromate, we can, by increasing this, so shorten the scale of gradation as to obtain a brilliant print from even the flattest and thinnest negative. It is, of course, impossible to give exact formulæ for every class of negative, but our experience is that with the average gelatine negative of the present day, the addition of silver chromate is always advisable, if rich prints are required.

The next point we have to consider is the amount of chloride to be used, assuming that a sheet of paper of 480 square inches, that is, 20 by 24, is to be sensitised. We shall roughly require half an ounce, or 240 minims, for the area, and assuming that arrowroot is used, the correct amount of chloride is about 8 grains, or practically a 3 per cent. solution. The amount of citrate should never be

more than one-fourth to one-third of this. The amount of arrowroot may be 4 or 5 per cent., so that our sizing and salting solution will have the following composition:—

Arrowroot	384 grains	40 grammes
Ammonium chloride ...	288	30
Citric acid	30	3
Sodium carbonate ...	60	6
Water to	20 ounces	1,000 ccs.

To make this, the proper way is to rub the arrowroot up into a fine cream with about 3 ounces of water, bring 12 ounces of water to the boil and gradually pour the arrowroot cream into the boiling water stirring continuously, and then boil for ten minutes, stirring all the time; dissolve the salts in the remaining 5 ounces of water and add to the arrowroot paste, allow to cool, filtering whilst warm if necessary, though this should not be required if the above instructions are properly carried out. Then measure out the quantity required for the area of paper, which can be easily calculated from what has been said above, and pour the solution on to the middle of the paper. Spread quickly

over the surface with the flat brush, passing this to and fro lengthwise, then up and down. Now abandon this brush, take up the round one, and with small circular strokes even the size all over, working with overlapping strokes, till the whole surface of the paper is covered. Continue this process until the paper begins to appear surface dry when it may be hung up by means of wooden clips to dry. This is practically the method of working with all the sizes, and although it may seem difficult at first, it is actually more formidable in the reading than in the performance.

With regard to the above formula, it will be noted that we have suggested that citric acid and carbonate of soda be used. Naturally the actual sodium citrate may be obtained, or potassium citrate used instead, but we have preferred to recommend the above because we have assumed that citric acid and soda are in everyone's dark-room, and further that the two citrates are so deliquescent as to be a trouble to keep.

In our next article we shall proceed to consider the other sizing solutions, the silvering, and operations subsequent to printing.

PAPERS ON PRACTICAL PHOTOGRAPHIC OPTICS.

I.

The following article on "Focussing Scales and Depths of Field," by J. H. Taylor, is the first of a short series by different writers, who will concern themselves with certain practical questions which interest the user of a lens. Subjects of the further articles are:—"Lens Calculations Without Arithmetic," by A. Lockett; "Discs of Confusion, and Distances Beyond which all Objects are in Focus," by the Rev. T. Perkins, M.A.; and "The Speed of Telephoto Lenses when Employed on Near Objects," by Chas. Louis Hett.—Eps.

PROBABLY most hand-cameras are not provided with a ground-glass focussing screen, and have to be focussed by means of a scale and pointer, and frequently when our tour with such a camera I have wanted to know several particulars which could only be known by calculation. For instance—How much of some view will be in good focus with a certain stop? or, again, if the weather is dull, as I expose by hand without using a tripod, I want to know the largest stop which will give fine detail over the desired area. Again, I often wish a moderate diffusion of focus for the unimportant objects, while keeping the principal object sharp, but, as I object to excessive fuzziness, I want to know what stop will give the required slight diffusion. The Cornex Index largely meets these requirements, though the divisions on it are somewhat minute. Messrs. Welborne Piper and Bolas have suggested a magnified scale and have designed a sort of circular meter for the same purpose on which the consecutive depths of field are marked. The idea is a most excellent one, the only objection being that a separate meter is required for each lens. This objection, of course, cannot be quite overcome, but the diagram which I have designed and append is so compact that all the information required can be obtained from it almost at a glance for any lens and any stop ever used in hand-cameras, and by a simple process of proportionate interpolation for other lenses not given in the diagram.

A Focussing Indicator.

This diagram replaces long and elaborate tables of consecutive depths of field, on which of course it has been founded. It is drawn accurately to scale, and consists of two parts—first, the scales of distances at their proper intervals apart for each lens, and secondly the indicator on which the stop

numbers are marked: To use it the indicator should be cut out along the dotted lines or else carefully traced; its upper edge should then be placed along the line of the scale belonging to the particular lens in use, and the arrow pointed to any distance marked on the scale; then the stop numbers on each side of the arrow point to the extreme distances between which all is in focus, allowing 1-100th of an inch for diffusion of disc. Examples will make this more clear. Suppose we are using a lens of 6 in. equivalent focus, and the principal object on which we sharply focus is 12 ft. distant; we require to know how much beyond and how much nearer will be in good focus if we use F.11.3 stop. We therefore place the arrow to 12 on the scale for a 6 in. lens and find that the F.11 marks on the indicator point to about 8½ and 22. This means that by focussing on 12 ft. all objects will be in focus from about 8 to 22 ft., using F.11.3 stop. If we had used F.4, only objects from 10 to 14 ft. would be in focus, while with F.32 all would be in focus from 5½ ft. to infinity.

In Practical Work.

Again: suppose we are working with a 5½ in. lens and wish to photograph a group, the nearest of which is 10 ft. away and the furthest 30 ft., what stop must be used to get both extremes in focus, and on what distance must we focus, it being understood that we want to give as rapid an exposure as possible. Now it would not be correct to focus on 20 ft., that is, halfway between 10 and 30, for if we did so, and used F.8, we should find on developing that the near person was out of focus though the person at 30 ft. was in good focus. This follows from the fact that the far depth of field is always greater than the near depth; in other words, sharpness of focus extends much further beyond the point focussed than it does on the near side. If now we use the diagram and place the arrow so that it points halfway between 10 and 30 on the scale for a 5½ in. lens, we shall find it pointing to about 15 ft., which may be called the optical mean between 10 and 30, and which is the point on which we must sharply focus. We shall also see that 10 and 30 are not well included between the two F.8 marks, so that F.8 cannot be used; whereas the two F.11 marks do include 10 and 30, showing that F.11 is the largest stop that will give all the group in good focus.

DEPTH OF FIELD SCALES

INDICATOR

COPYRIGHT.

(Cut out Indicator along dotted lines.)

To Control Diffusion.

A final example will show how the scales can be used to get artistic results with the hand-camera. We wish to have a figure at 20 ft. distance sharply focussed, but for some bushes only 12 ft. away we want a slight diffusion of focus, sufficient not to attract attention from the figure, but not so much as to be utterly blurred. What stop of our 6 in. lens must we use? On applying the indicator arrow to the 20 ft. mark, we find that the F.11 marks include 12 ft., so that if we use F.11 the bushes at 12 ft. will be sharply defined. On the other hand, the F.4 marks fail by a long way to include 12 ft., so that with F.4 the bushes would be unpleasantly blurred. The F.8 marks, however, only just fail to include the 12 ft., and thus by using F.8 we shall get the desired slight diffusion of focus for the bushes.

A Scale for any Lens

Incidentally it may be mentioned that the form of scale as given has the advantage that, by ruling lines at proportionate distances from those given, we can quickly get a scale for other lenses, e.g., required a scale for a lens of $5\frac{1}{2}$ in. focus; rule a line parallel to and half way between the lines for 5 in. and $5\frac{1}{2}$ in. lenses; draw cross lines connecting the respective feet marks, and where these cut the new line, mark in the distances. This is much shorter than calculating out the consecutive depths of field for each lens and each stop, and is quite accurate enough for all practical purposes.

For general use, the diagram in the form given is sufficiently convenient as it can be copied to scale and then easily carried in a pocket book; but for those who desire a circular-revolving form, I have devised one which shows readily the depth of field for lenses of from $4\frac{1}{2}$ in. to 9 in. focus. J. H. TAYLOR.

SCOTTISH NATIONAL PHOTOGRAPHIC SALON.—The forthcoming Third Annual Scottish Photographic Salon will be held in Dundee, the previous exhibitions having taken place in Perth and Glasgow respectively. Since the institution of the Federation in the beginning of 1903 great strides have been made in adding to the strength of the forward movement, and now some thirty-six societies have joined hands for mutual support and encouragement. The Salon is the outcome of

this combination of interests, and arrangements for the meeting of 1906 are already being made. The Committee have secured the Victoria Art Galleries in Dundee for the hanging of a representative collection of Scotland's photographic work of the year. The opening date has been fixed for Saturday, January 13, 1906. Scottish workers everywhere please note. Mr. V. C. Baird, Broughty Ferry, is Hon. Secretary, to whom all communications should be addressed.

FINISHING ENLARGEMENTS IN COLOURED PASTELS.

Of all the methods of finishing enlargements, perhaps the one about to be described is the most neglected. And yet, holding as it does an intermediate position between finishing in water-colour and oils, it has much of the delicacy of the former combined with the solidity of the latter, resembling very closely work done in flatted oils. Moreover, with it, it is not only possible to give the correct tint of human flesh, but also to obtain an ideal representation of it. Undoubtedly, the reputation of pictures in coloured pastel has been damaged by their being done in vivid inartistic colours, owing either to the proper pastels not being at hand, or to the poor judgment of the artist in selecting them. But this should not deter photographers from using the method any more than the common "club" oil paintings should keep them from reproducing photographs in oils. All that is necessary is sound judgment combined with suitable materials and artistic skill. Broadly speaking, the work is similar to finishing enlargements in monochrome pastel, only decidedly more difficult to accomplish, inasmuch as the original tone of the photograph has to be obliterated by opaque colours.

Materials Required.

An adequate supply of soft French pastels is necessary, and as it is difficult to choose the most useful tints, especially as they are listed in the catalogues by numbers instead of names, I give the following list as comprising the most essential shades:—

Reds and Pinks.—Serie A, ochre clair No. 9; serie B, laque carminée No. 25; serie F, laque carminée No. 21.

Browns.—Serie A, gris feutre No. 75; serie A, T. de sienne arinée No. 5.

Yellow.—Serie A, jaune de chrome No. 39.

Greens.—Serie B, vert feuille No. 163; serie B, vert anglais No. 156.

Blue.—Serie A, bleu indigo No. 36.

Neutral.—Serie B, brun feuille No. 166.

Blacks.—Serie C, noir No. 27; serie B, brun noir.

The description given above is sufficient for the purposes of ordering, the general price of each pastel being twopence, and a few of the more expensive shades costing double or treble that sum.

In addition to the above, an assortment of semi-hard pastels would be an advantage, but is not absolutely necessary at first; also additional shades of some of the soft pastels would be useful, but as it is possible to blend the colours together, most of the ordinary tints required can be readily made. The mixing is easily done with the aid of a palette knife on a chamois leather pastel board, or more perfectly in a little glass mortar with the aid of a pestle. In addition to one or two pastel boards, a piece of soft velvet rubber, some pumice powder, cotton wool, a piece of putty rubber, and a retoucher's knife or artist's scalpel will be needed.

How to Begin.

Enlargements to be finished in the pastel must be made upon rough surfaced paper; the smooth varieties yield very disappointing results. And if they are to appear similar to oil paintings, they should be mounted upon linen canvas on a stretcher.

Almost any portion of the picture (except the flesh) may be commenced first, but it is better to attend to the background before the accessories, and do the flesh work last of

all. When a tint is to be laid on heavily the pastel is applied with a hatching movement over the part direct, and then rubbed over smoothly with the finger tips. A stump, or piece of cotton wool can be used, but nothing, in my experience, equals the direct application of some portion of the hand. Should the artist's hands be naturally inclined to be damp, the inconvenience may be obviated by rubbing powdered pumice over them.

When only a medium depth of tint is required it is best to charge the fingers with powdered colour by applying them to the pastel pad, and then work them over the picture, instead of applying the pastel direct. For lighter shades the fingers may be less heavily charged with colour, or a charged stump or cotton wool can be substituted. In pastel work the rule is to put on the necessary depths of tint *at first*, for should the attempt be made to do it by successive applications, it will probably be impossible to obtain the maximum intensity required, as each time one covers the same part with colour the more the surface refuses to take it. Soon after commencing, the beginner will observe the necessity for shading the parts coloured. This is done by applying darker tints of the same colour mixed with a neutral tone to subdue its brilliancy. Should any error of judgment have crept in, the work may be removed with pumice powder applied on the fingers or on cotton wool, although if the tint has been laid on heavily it may be necessary to use either the velvet rubber, or putty rubber charged with pumice powder, care being taken in either case not to abrade the delicate surface of the paper.

Colouring the Flesh.

After the background and accessories have been done, the draperies and hair should be coloured, and finally the flesh, which is by far the most difficult to do. A duplicate photograph must always be used as a guide in keeping the likeness, for since the colours are opaque, it is easily lost, and a few brief touches will cause the features to lose all likeness to the original. My own method is to do the eyes first, together with the shadows under and above, and then the forehead and brows. In working, bring the eyes out more boldly than appears (at this stage) to be correct, otherwise, when all the other parts are coloured the picture will appear insipid and flat. It is, indeed, a nice point for judgment, and the way it is done will decide the vigour of the finished whole, for naturally the rest of the features will be brought out to such a depth as to harmonise with the part coloured first.

In working small parts like the eyes, the occasional use of putty rubber will help, as also will the retoucher's knife.

Attend next to tinting the rest of the flesh, and then the colour on the cheeks and the shadows should be worked in. When colouring the lips, take care to keep the shadow upon the upper lip in "statu quo," and let the light upon the lower one be properly centralised. It may be done by erasing the colour where necessary with rubber or knife. It is useful during the work to occasionally walk back a few paces and view the picture from a little distance. Defects unnoticeable close at hand will readily be noticed there, and one should not be satisfied until the picture appears satisfactory, both upon close inspection and with more distant observation. When well done, the life-like charm about it will amply repay the artist for the labour bestowed thereon.

ARTHUR WHITING.

A MANAGER of a laundry at Hayward's Heath, named Alfred Hassan Medina, committed suicide on Saturday by taking cyanide of potassium. In response to his wife's request that he should come in to dinner he said he would do so presently. He then went into a

room where he kept his photographic chemicals, drank the poison, and went in to dinner. His wife was about to leave the room, when he said: "Don't go, I have taken something," and shortly afterwards expired.

THE WEEK IN HISTORY.

The First Practicable Photo-etching.

FIFTY-TWO years ago on Sunday next—in the *Athenæum* for April 30, 1853—Fox-Talbot was describing in detail the process of photographic engraving invented by him, and patented in 1852. The process was the forerunner of the one described last week in this column; the later modification embodied certain radical improvements. Both are intaglio methods, allied to our modern photogravure, and the first is interesting from the historical standpoint, because it establishes Fox-Talbot as the discoverer of the sensitiveness to light of a mixture of gelatine and potassium bichromate, and of the difference, in certain ways, between the exposed and unexposed mixture. His photo-engraving process appears to have been the outcome of troubles in making perfectly permanent "photographic" prints. The proper use of the fixing-bath was not understood in Talbot's early days, and he himself preferred to take refuge in his salt or iodide methods of fixing to trusting in hyposulphite, with all its vagaries. A mechanical reproduction process would absolve him from these difficulties, and the process which he thus devised was briefly as follows:—A coating of bichromated gelatine was applied to a steel plate, dried, and the plate exposed to light under a positive until a visible image—yellow on a brown ground—was produced. The plate was then placed in cold water for a short time, dipped in alcohol, dried, and etched. As an etching agent, Talbot used first platinic chloride, applying it with a camel-hair brush, and afterwards washing the plate in water, and removing the gelatine coating.

In order to break up the tones, Talbot devised the screen of gauze or net, which he termed a "photographic veil," and he impressed it upon the sensitised steel plate by a preliminary exposure. This method, as I mentioned last week, he further developed in his patent of 1858.

Stripping with Hydrofluoric Acid.

IF I am not mistaken, the use of hydrofluoric acid for removing the films of gelatine negatives is exactly twenty-three years old to-day, for its first publication was on April 28, 1882 in "The Photographic News." There it was stated, in an editorial article, that Herr Joseph Plener had discovered the ability of hydrofluoric acid to loosen a gelatine film from its glass, and I cannot find an earlier note of the fact in photographic periodicals or text-books. Plener used the acid dissolved in water, and therefore obtained enlargement of the film; but he mentions the use of spirit to bring the gelatine afterwards to its original size. The suggestion is made that by squeegeeing a sheet of gelatine on to the film, and removing the two together, a negative would be stripped in the course of twenty minutes or so. That is longer than need be taken at the present time by the method of Middleton and Holcroft, which I see the editors gave

last week in reply to a correspondent, and a very reliable and rapid method it is—to that I can testify.

Moist Collodion.

The process which for some years was largely worked in preference to the orthodox wet-collodion was that of Crookes and Spiller, first published fifty-one years ago in the "Philosophical Magazine" for May, 1854 (p. 349). I have referred already to the way in which wet-collodion progressed to a dry process by the use of substances which would keep the sensitive film in a slightly moist condition. The first agent which Crookes and Spiller used for this purpose was nitrate of zinc. After the usual silver nitrate bath of 30 grains to the ounce, they immersed the plate in:

Nitrate of zinc	2 ounces
Nitrate of silver	35 grains
Water	6 ounces

for five minutes or more until the film of collodion was saturated, and then took it out and allowed it to drain upright on blotting-paper until all the surface moisture had been absorbed. The plates could thus be kept in their sensitive condition for a number of days without suffering in sensitiveness. Before development they were plunged for a few seconds into the original silver bath. Crookes and Spiller afterwards substituted nitrate of magnesium for that of zinc, and they also used potassium acetate for the same purpose. The "Liverpool Photographic Journal," afterwards *THE BRITISH JOURNAL OF PHOTOGRAPHY*, for the year 1854, shows that this process was much discussed at this time; but many other workers appeared to perfect these "dry-plate" processes with the bath, and experiments in this field cannot be said to have ceased until gelatine dry plates came into use.

Auto-Development.

The idea of a plate or paper, self-contained, as it were, is one to which inventors have returned again and again. The notion is probably a legacy from the calotype process, the sensitiser of which—silver nitrate and gallic acid—was almost identical with the developer, and under certain conditions the picture might develop without the after application of a separate solution. I hear that there is on the German market a gelatine plate which contains its own developer within itself, so I am interested in looking back fifty-five years to May 1, 1850, when poor Scott Archer, who a year before had worked out the wet-collodion process, was writing in "The Chemist" of pyrogalllic acid as a developer in the albumen process of that time. He applied pyrogalllic acid, silver nitrate, and acetic acid to the paper, and he writes:—"There is one advantage in the above preparations, that no second wash is necessary to bring out the picture."

HISTORICS.

PROCESS Instruction at Manchester.—Two series of lectures commence on May 1 in the Photography and Printing Crafts Department of the Municipal School of Technology, Manchester. The first, on "Collodion Emulsion," is by Mr. Charles W. Gamble, and is based on a syllabus as follows:—Outline of the method of preparation of a collodion emulsion. Commercial emulsions. The preparation of glass. Coating plates. Exposure and development of plates. Sensitising collodion emulsion for orthochromatic work. Photographing coloured objects. Screen negative-making with emulsion for process block work. The second, on "Process Block Making," by Mr. R. B. Fisherden is to deal with the line and half-tone processes; character of the originals suitable for photographic repro-

duction; limitations of the processes; the relation of the fineness of screen used in half-tone block-making to the method of printing; negative-making and etching for line and half-tone blocks; essential characteristics of a good printing block; mounting the etched plates, and the appliances used for the purpose in modern practice; mechanical overlays; the tri-colour process applied to letterpress printing.

AN attractive exhibition of photographs is on view in the windows of Houghtons, Ltd., 88 and 89, High Holborn. The pictures consist of a selection from the winning prints in the recent Barnet competition. They are tastefully arranged on screens, and with a display of other Barnet products afford a striking example of successful window dressing. As an advertisement it should prove quite satisfactory to all concerned.

SOME RESULTS OF LENS TESTING.

[A Paper read before the Royal Photographic Society.]

THIS paper should, I think, have been described as "The expression of results of lens testing," as it is concerned with a method of expressing results of tests quite as much as with actual results.

The best test, and the one by which all lenses must be finally tested, is their capacity for giving a good picture under the varied conditions which may arise in practice, but it is not very pleasant, if we discover that the lens is unsatisfactory only after many plates have been wasted.

A Photographic Test.

We want a simple test, which will give us, with one exposure, the information which it would cost many plates and much labour to obtain in the ordinary manner. There are, it is true, many visual tests which will give a great deal of valuable information, but they all suffer from the defect that the observations are not made with the light to which the photographic plate is most sensitive, so that a photographic test is to be preferred if it gives the desired information with anything like the same labour; but it is still important to compare the positions of the best visual and best photographic focus.

In addition to this test of the actual value of a lens system, it is frequently most important to determine the aberrations of a lens with a view to subsequent modifications of the design in order to give better results.

The Hartmann Method.

I propose to describe two photographic methods, one for each of these two distinct purposes, one making use of a photograph of a definite, external object, and the other of a representation of the beams of light that pass through the lens.

In Professor Hartmann's method a small, bright light, at as great a distance as is convenient, is used; and a diaphragm, with small circular apertures in it, is placed in front of the lens, so that small isolated beams of light may pass right through the lens system. If these beams were examined at the focus of the lens, an image of the source would be observed, but at any point inside or outside the focus a number of small circular spots of light, corresponding almost exactly to the diaphragm, would be seen; and the centres of these spots may be taken to be points on the rays from the centre of the source to the centres of the apertures in the diaphragm. In order to completely define these rays, another photograph, at a measured distance from the first, is required; and for ease and accuracy of

Fig. 1.

measurement, it is necessary that one of the photographs should be taken inside and the other outside of the focus, and, as nearly as possible, equidistant from it.

In the diagram two apertures, symmetrically placed with regard to the axis, are represented; and the corresponding spots, A B and a b, are shown in the figure. It is evident that by connecting A B and a b, the exact crossing point of the rays may be determined, and thus the aberrations of any portion of the lens, compared with the other portions, may be obtained. It is customary to arrange that the diaphragm shall have apertures in vertical and horizontal lines, so that the various rays of light will cross over at one particular spot, and according as they do so or not the lens is good or inferior.

I have here a diaphragm, with five apertures, one central, and the other four symmetrically arranged, so as to form vertical and hori-

zontal lines crossing one another and the images formed on the plates are represented in the diagram. It is evident, from the figure, that there is a considerable amount of aberration.

Arrangement for Practice.

The information given by the method may be made as complete as is desired by placing a number of bright sources of light at regular intervals in a line at right angles to the axis of the lens; but I have

Fig. 2.

found it more convenient in practice to arrange so that the lens will swing about a vertical axis, approximately through the back nodal point, exposing, with the one light, the various portions of the plate in succession. In practice it is found desirable to take the two photographs at a distance of 15 mm. inside and the same distance outside the focus; or at a greater distance in the case of very bad lenses. The illumination employed in making these tests was an electric arc light,

Fig. 3.

condensed on a small aperture of about 2 mm. diameter, placed at a distance of 9 metres; the exposures were varied between 1 and 6 seconds, the shorter exposure giving the best results, although the diffraction rings surrounding the dots enabled measurements to be made even when the plates were very much over-exposed. Figs. 3 and 4 give the actual photographs in the cases of a single achromatic lens and a well-corrected anastigmat, the photographs were taken,

Fig. 4.

intentionally, farther from the focus than would be the case in actual practice. The diaphragm is placed as nearly as possible in the position of the iris of the lens system, partly because this indicates the cutting off of the lens for different angles, but principally in order that the actual results obtained should conform to the usual nomenclature of aberrations. For example, the position of the focal lines, as distinguished from the effect of coma, are obtained from the inter-

sections of rays equidistant from the centre of the stop, while the value of the coma is obtained from the distance between the central line and the intersection of these two outer beams.

The point F (Fig. 2) would denote the focal line, any focussing at the intersection of the lines 1 and 2 or 3 being attributed to coma.

It is characteristic of this method as distinguished from all other methods that the aberration of coma is shown as a definite measurable quantity, and all the defects of a lens can be measured or, when they exceed a certain amount, easily seen.

Dr. Hartmann used this method with the idea of obtaining the longitudinal aberrations, especially of telescope objectives. He measures the positions of the centres of the various apertures and calculates the crossing point of two rays as in Fig. 1. But the method seems specially applicable to the accurate testing of photographic lenses because it is possible to express the results in the same form as the results of calculations, while the various oblique rays can be tested more easily than by calculation. For this purpose I propose in future to use additional apertures on diagonal lines.

The labour of taking the photographs is much reduced by swinging the camera about the nodal point of the lens, but the labour of measuring the photographs is very great. For simplification I use a drawing camera, the microscope magnifying 50 to 75 times; it is then possible to draw the centres of the various spots with an accuracy of 1 mm., i.e., 1-50th mm. to 1-75th mm. on the original plate. The various points in one diagram are joined up to the corresponding points in the other, and any variation made by the lines in crossing gives the longitudinal aberrations.

But in interpreting the photographs I prefer to express the results as lateral aberrations. Referring to Fig. 1, if the images are equidistant from the focus, the lateral aberrations of the rays A B are expressed by

$$\frac{CA - ca}{2} \text{ and } \frac{BC - bc}{2}$$

If the distances be not exactly equal, the aberrations will be expressed in the same form by enlarging or reducing one of the photographs. In using the drawing camera, a drawing is made of the positions of the centres of the spots in the photograph taken inside the focus. The magnification is then adjusted till the central figure in the diagram outside the focus is made to coincide as nearly as possible with the corresponding figure inside the focus, and with this magnification the remaining figures are drawn off.

Fig. 5 represents the drawing for a lens, the spots being from the inside focus diagram and the crosses from that outside the focus. Where no cross appears, the error on the photograph was less than 1-50th mm., corresponding to a lateral aberration of .01 mm.

The lateral aberrations in the other cases are expressed by the distance between the dot and the corresponding cross on the scale shown.

Small alterations in the magnification of one of the diagrams correspond to slightly different positions of the focal plane, and the accuracy with which the two magnifications agree gives the accuracy with which the focus was determined visually. The diagram shows not only the lateral aberrations, but also the cutting off by the lens mount, and it is remarkable, in some cases, how the cutting off coincides with a marked improvement in the astigmatism.

The distance between the two photographs should be recorded, as this enables the aperture ratio corresponding to each opening of the diaphragm to be subsequently calculated.

A Standard of Correction.

A photographic lens may be regarded as perfectly corrected when no aberration exceeds 1 mm., i.e., when no error of 10 mm. is shown in the drawing, when each photograph is magnified fifty times.*

The diagram of a good lens shows that this standard is hardly obtained throughout the whole field; but an error of 2 mm. would not produce any noticeable effect on an actual photograph, unless it were magnified for use in telephotography.

Zschokke's Method.

There is one other test to which I wish to refer, because it is within the power of any amateur, and probably it is the best simple test which expresses directly the various defects of a lens. The test is, I believe, due to Dr. Zschokke. It uses the light to which the photographic plate is most sensitive, and the results are obtained in a single ordinary photograph. The object chosen is a flat object with sufficient detail, generally, either in series of horizontal and vertical

Fig. 5.

lines, or a series of circles and radii; and either the object or plate must be set at an angle to the axis of the lens. The camera for the purpose of the test is constructed to carry a plate, inclined to the axis of the lens. The centre of the object is focussed on the ground glass, as nearly as possible, and an exposure is then made, under what might be considered the best conditions for the object, but of course using the aperture which it is desired to test. The resulting negative will obviously show a falling off at the top and bottom; and, if the lens were perfect, the best definition would be along one horizontal line. Any defect in the nature of spherical aberration is shown by the absence of good definition at any point, while the amounts of astigmatism and curvature of field can be charted out and numerical

* We are unable to reconcile these figures. Apparently 10 mm. should read 50 mm.—EDS., B.J.P.

estimates obtained if the points at which the horizontal and vertical lines appear sharpest be marked on the plate.

The anastigmat curves can be drawn, and these curves have their

Fig. 6.

ordinates magnified in the ratio of 4:1 (Fig. 6). This specially constructed camera shows all aberrations on the same scale. For ordinary purposes, however, it would be sufficient to use a camera with a swing back, tilting the plate to an angle of 10 deg. or 15 deg. if

possible; and instead of a series of horizontal and vertical lines, or circles and radii, as object, a sheet of well-printed matter might be used. This method has the advantage of supplying a permanent record of the defects of the lens. It is used, I have been informed, by one of the largest manufacturing firms. The method is subject to the possible defects of bad exposure or development, but if these processes are satisfactorily carried out, the results of the test will be perfectly satisfactory.

To obtain the scale of the aberration curves, it is necessary to have a true square or circle in the centre of the field; this will reproduce as an oblong or an ellipse, the greater length being vertical, and thus the scale can be obtained; if AC and AB (Fig. 6) are the two dimensions of this rectangle, the magnification is AC:BC.

S. D. CHALMERS, M.A.

INDUSTRIAL ALCOHOL. THE PHOTOGRAPHIC QUESTION.

LAST week we summarised the report of the Lord Chancellor's Committee on Industrial Alcohol, and gave the general conclusions to which the members of the Committee were led. In forming an opinion on the importance of pure alcohol in British manufacture, the Committee did not lose sight of the photographic craft and industry, and several witnesses were called solely with the object of stating the case for photographers, photo-engravers, and photographic manufacturers. Their evidence is now published in the bulky "Minutes of Evidence Taken Before the Departmental Committee on Industrial Alcohol" (Wyman and Sons, Limited, Fetter Lane, London, E.C. 2s. 4d.). The chief photographic applications of a possible untaxed spirit to come before the Committee were:—

- (1.) Collodion, for the wet collodion process.
- (2.) Collodion emulsion, for negatives.
- (3.) Collodio-chloride print-out emulsion.

The witnesses giving evidence on the needs of the craft or industry in the matter of pure alcohol were:—

Mr. Harry Entwistle, representing the Association of Manchester Process and Wood Engravers.

Mr. Albert Thomas Clarke, representing the Hentschel Colour-type Co., Limited.

Mr. T. Macwalter, representing Messrs. Elliott and Sons, Limited, Barnet.

These gentlemen may be said to speak for process and other workers of the wet collodion process, for users and makers of collodion emulsion, and for makers of collodio-chloride paper.

In Wet Collodion.

The statements to the Committee that methylated spirit was unsuitable for the preparation of collodion intended for the wet-collodion process was actively combated by Dr. T. E. Thorpe, who, examining Mr. Entwistle, asked:—

Are you not aware that large quantities of photographic collodion are made with methylated spirit?—Yes, I am quite aware of that.

And a good collodion, too?—It is not good-keeping collodion.

I have used such collodion frequently. What happens to it?—You get organic impurities in the silver bath.

What do you mean by "organic impurities in the silver bath"? What are they?—So far as I understand, in methyl alcohol there are oily impurities from the crude wood spirit. I take it that it is crude wood spirit in the methylated alcohol.

There is no oily matter in it?—Not from the tarry distillate of the wood?

No, there is nothing oily in it at all—not what we chemists would call oily.—There is acetone, is there not?

There is. And acetic acid?

No.—Of course, I am not a chemist; I am only a photographer.

But the witness maintained that the presence of methylated spirit was responsible for uncertainties and vagaries in the working of wet-collodion; although he admitted that, owing to insurance difficulties, his firm used mineralised spirit, since the "ordinary" spirit had to be purchased and stored in quantities of not less than five gallons.

Mr. Clarke spoke strongly to the same effect in stating that he made collodion for his firm with absolute alcohol, as he found a collodion made with methylated spirit fouled the silver bath and yielded an inferior class of half-tone negative. The dot in the half-tone process had ragged edges, instead of cleanly and sharply defined edges.

And Collodion Emulsion.

A suggestion of Mr. Clarke's to the Committee was that collodion should be made in bond, and from that connection it transpired that the present restrictions on the use of pure alcohol prohibited the manufacture for re-sale of the collodion emulsion made for their own use by the Hentschel Colourtype Co. It was stated that the present conditions prevented competition with German makers of the collodion. If made in bond under Excise supervision, the manufacture of collodion emulsion would be commercially practicable, if on a scale as large as would be necessary for distribution through the trade; but the witness thought it would not be worth the while of a photo-engraving firm only to pay for that supervision.

Denaturants for Collodion Emulsion.

Mr. Clarke put forward pure methyl alcohol as a possible denaturant of spirit for the manufacture of collodion emulsion, and it was thought that a high-grade wood naphtha might be used. Both suggestions, however, arose without any preliminary experiment, and Mr. Clarke's mention of a pure methyl alcohol appeared to have been made on the assumption that the wood spirit used for methylating alcohol was a crude, impure product, and on Dr. Thorpe pointing out that the added wood spirit is a fairly pure article, Mr. Clarke apparently withdrew his opinion that denaturing with pure methyl-alcohol would be any improvement.

Collodio-chloride Print-out Emulsion.

Mr. Macwalter described the drawbacks of both mineralised and "ordinary" (or "manufacturer's") spirit. Both produced certain different, but distinct, defects in collodion papers. In his opinion a manufacturer would willingly pay double the price for a spirit with-

out these disadvantages. As one possible, but inadvisable denaturant, ether was named, but Mr. Macwalter reminded the Committee that it interfered with the usual practice of soaking the pyroxyline in the alcohol alone for twenty-four hours before adding the ether. He thought, however, that 10 per cent. of ether might be added. Other denaturants, suggested by the Committee and dismissed by the witness as unsuitable were animal oil and turpentine. Benzole might possibly be employed.

In Dry-plate Manufacture.

Methylated spirit, said Mr. Macwalter, in the course of examination, was suitable for use in the manufacture of dry plates, except that it was difficult to obtain it of sufficient strength. He would like spirit of .807 sp. gr., and stated, on the authority of spirit vendors, that the Excise regulations made it impossible to supply that strength. Dr. Thorpe asserted that 97 per cent. alcohol was obtainable in any quantity, and that, it was thought, would be as strong as necessary.

BLUE FOCUSING SCREENS.

THE advantages of using a piece of blue glass as a view finder have been long recognised by landscape and other outdoor photographers, but the fact that the view on the focussing screen will also give a much nearer approximation to the resultant monochromatic version of the scene portrayed, if the ground glass is coloured a blue tint, appears not to be so generally known as its usefulness warrants. The reason the scene appears apparently in monochrome when viewed through a blue screen is because the blue colour subdues much of the yellow and orange rays, which have the highest visual intensity in nature, although unfortunately their action on the ordinary plate is considerably less than that of the blue rays, freely passed by the coloured glass, but visually much darker in tone.

For Outdoor Photography.

The blue focussing screen is obviously more likely to be of use and assistance to landscape photographers than to those who essay portraiture or architectural work. In the two latter cases the photographer will probably find that unless the light is particularly good the image on the screen will be somewhat dark. The landscapeist, on the contrary, usually has plenty of light, and his subjects, moreover, are such that the monochromatic effect gained is likely to be more useful in the estimation of correct exposure consequent on the suppression of brilliant, but misleading colours.

Expedients for Indoor Use.

It is recommended, therefore, that the photographer should give the blue focussing screen a trial, if much outdoor work is being done, while if it commends itself also to the studio or indoor worker, seeing and composing the image on the screen, can be materially assisted by the adoption of the well-known method of aerial focussing by cementing pieces of microscopic cover glass on to the rough side of the screen with Canada balsam, thus rendering the grain invisible but retaining the blue colour. In focussing by the aerial method, the rays pass through the clear glass thus obtained, without being scattered or obstructed. It is quite possible to serve the image by the unaided eye, but it is not possible to tell when the front surface of the screen is exactly at the focal point of the lens. A focussing glass will, therefore be necessary, and one of the Ramsden type will be found most useful, as it can be set to suit the eye. Pencil marks or crosses should be made on the screen before cementing on the thin pieces of glass, and then the pieces of the focussing glass adjusted until the mark or scratch on the image are both perfectly well defined, otherwise the accommodating power of the eye will permit the racking in or out of the screen quite a perceptible distance without apparently affecting the definition of the aerial image. As finely ground blues will be found difficult to obtain commercially, methods for its preparation will be found useful.

How to make the Blue Focussing Screen.

Undoubtedly the best way to prepare the glass is to etch it with hydrofluoric acid. A piece of pale blue glass should be obtained, cut to the required size. The kind known as "pot" is preferable to "flushed" glass, which is coloured only on the surface. Make a solution of gelatine in water 20 grains to the ounce. Add 20 to 30 grains of sodium or potassium fluoride to each ounce of the solution, and coat your glass as when varnishing a negative, leaving as much gelatine on the plate as in coating a dry plate. Place on a levelling stand; and allow to set. Then rear up to dry. When dry, but not before, immerse the plate in a solution of hydrochloric acid $\frac{1}{2}$ oz., water 8 oz., allow to remain 30 seconds, and again rear up to dry. This latter operation may be advantageously varied by pouring on enough of the dilute acid to cover the plate and allowing it to soak into the gelatine. After a minute or two the surface will be dry enough to rear up to thoroughly dry slowly. When this is the case, clean off the gelatine, and the glass will be found to have an exceedingly fine matt surface, much finer than ordinary ground glass, and eminently suitable for camera work. If, however, this process is thought too tedious or complicated, the surface of the glass can be ground in the ordinary way by means of fine emery powder. The plate to be ground should be placed on a flat table on a pad of newspaper. A small pile of the powder (the finest obtainable) should be placed in the middle and moistened with a little dilute sulphuric acid. If a small piece of thick plate glass is now worked carefully over the surface, with a circular motion, it will be found that the emery ground between the two surfaces has covered them with minute scratches. If the process is continued—adding more emery, acid, and water as required, the entire surface of the glass will soon become obscured with these fine scratches, and a finely-ground screen remains.

An Alternative Method.

An alternative method of preparing a blue focussing screen may also be found useful if the etching or grinding is considered troublesome; but it does not give a surface that can be regarded as permanent, although the fact that ordinary white glass can be used is in its favour. Take any ordinary dry plate of the required size and purposely fog it by striking a wax match and holding it about a foot or two away from the plate for, say, five to ten seconds. Develop the fogged plate, until all the surface appears one uniform grey of thin half-tone. Now fix and wash in the usual way. After thorough washing, bleach this grey veil to white in the ordinary intensification bath of mercuric chloride. Again wash fairly well. Dissolve in, say, 6 oz. of water a penny packet of blue dye, making it a fairly strong, i.e., dark solution. Soak the bleached plate in the blue dye when in a very short time the gelatine will become stained. Having stained the gelatine not quite so dark as it is wished to appear when dry, give the film a quick rinse under the tap, shake off all superfluous water, and set up on edge to dry.

COLLOTYPE WITH MERCUROUS OXALATE.

In the current number of the official organ of the Italian Photographic Society, Dr. Luigi Castellani gives the results of his experiments in the application of mercury salts to the production of a grain in the making of colotype plates.

Both Namias and Lüppo-Cramer have emulsified mercurous sulphide and oxide, but the emulsions were useless, and in the case of mercurous oxalate it was found impossible to emulsify this. Many mercury salts are decomposed in contact with gelatine with the evolution of heat, and such emulsions rapidly turn grey, in consequence of the liberation of metallic mercury and its oxides. The emulsion of mercurous oxalate and linseed oil suggested by Namias is useless, particularly on account of its very slow drying.

Unstable Mercury Emulsions.

If a solution of Winterthur colotype gelatine is prepared as follows:—

Gelatine	8 g.
Water	50 ccs.

and to it whilst warm is added

Oxalic acid	2 g.
Water	25 ccs.

a gelatinous solution is obtained, which is turbid probably on account of the formation of calcium oxalate, due to the hard water used. If to this solution now the following is added:—

Mercurous nitrate	8 g.
Water	25 ccs.

a homogeneous white emulsion with very fine grain is produced, which does not set, even after a long time. Assuming that this want of setting power* to be due to excess of acidity, as many acids prevent gelatine solutions from setting, another experiment was made replacing the oxalic acid by ammonium oxalate, the above given solutions of gelatine and mercurous nitrate being used, and

Ammonium oxalate	8 g.
Water	25 ccs.

The oxalate solution made warm was added to the gelatine, and then the mercury solution also heated, and an extremely fine grained homogeneous emulsion was formed, but which immediately turned grey through reduction of the mercury salt.

Another experiment with the first formula and an increased quantity of gelatine, set firm, but turned grey, thus proving that gelatine in the presence of oxalic acid does not decompose the mercury salt, but that as soon as an excess of gelatine is used, decomposition sets in, metallic mercury, mercurous oxide, and mercurous hydrate being formed. If the mercury salt is separately prepared and mixed with gelatine decomposition also sets in, and to prevent this the author tried the addition of a little sodium chloride, which would form mercurous chloride, with the nascent mercury, and thus prevent further decomposition.

A Stable Mercurous Oxalate Emulsion.

In order to prevent the formation of mercurous chloride instead of oxalate, the latter was prepared first by adding 200 ccs. of a hot 1 per cent. solution of oxalic acid to 50 ccs. of a 16 per cent. solution of mercurous nitrate, collecting and washing the precipitated oxalate

* Oxalic acid entirely prevents the setting of weak gelatine solutions, and advantage is taken of this property in the preparation of platinotype paper.—E.L.S. B.J.P.

NINE Hundred Dollars in Cash for Eighteen Prints.—The rumour is going about that a prominent photo-secessionist has received this amount of money from a well-known New York financier for eighteen photographic prints. If this is so—and the rumour bears traces of authenticity—it is up to the professional photographer to get busy

till there was no longer any acid reaction. To the thin paste thus obtained was added by degrees, and with constant stirring—

Gelatine	10 g.
Water	50 ccs.
Sodium chloride	5 g.

heated to 40 degrees C. A good homogeneous emulsion was obtained without any sign of decomposition. Equally satisfactory results may be obtained by using ammonium oxalate instead of oxalic acid.

If this emulsion be coated on glass in the usual way it will set in about a quarter of an hour, and the plates may then be set up to dry. On drying, however, crystals of oxalic acid or ammonium oxalate appeared, due to the emulsion not being washed.

Preparing the Fine-grained Emulsion.

The best method of making a fine grained emulsion is as follows:—

A. Gelatine	36 g.
Sodium chloride	18 g.
Water	360 ccs.
B. Mercurous nitrate (Merck)	24 g.
Water	250 ccs.
C. Oxalic acid	6 g.
Water	250 ccs.

B. and C. were mixed at 80 degrees C., and the oxalate allowed to settle, and then washed several times by decantation, and then placed on a filter and washed until there was no longer any acid reaction. Washing with hot water would certainly remove the acid more quickly but it cannot be used, because it decomposes the mercurous oxalate. Thorough washing is most important, or else the oxalic acid will crystallise out on the film. The warm gelatine was poured on to the damp oxalate a little at a time and thoroughly stirred and the mixture poured into a porcelain dish, metal must not be used, and left for several days, and then broken up by pressing it through mosquito netting and washed for six hours. The shreds of emulsion were then collected, melted in a water bath, and rapidly cooled. This is important, otherwise some of the mercurous oxalate separates out.

Employment in Colotype.

Glass coated with a substratum of potassium silicate and beer, as generally used in colotype, was coated with this emulsion, and a perfectly homogeneous film with a fine grain was obtained, when the drying was rapid. They were then sensitised in a 3 per cent. solution of potassium bichromate for three minutes.

Superb relief and very fine grain can be obtained with only a few minutes exposure on these plates to direct sunlight or diffused light, and they must then be washed with water and treated with a 5 per cent. solution of glycerine in water.

Ordinary colotype ink can be used, but the plates must be repeatedly inked and pulled before good proofs are obtained. An important point is that a plate which has been used can, after ten months, be again swollen in glycerine and again used; and, further, the author states that he thinks that if the process can be improved, it will be possible to obviate the usual heating for obtaining the grain.

The mercurous oxalate emulsion has been kept by the author for ten months in the dark without any sign of decomposition or fermentation. The oxalates of barium and calcium and the tungstate of mercury have also been tried, but all give a coarse grain.

or to admit that his non-professional brother is the better money maker, to say the least. Why is it that the big money in photography seems to be going to the men outside the profession? It is time that a record were made by those who have devoted a life study to photography and that the laurels be kept within the fold.

PROFESSIONAL PHOTOGRAPHERS' SOCIETY OF NEW YORK.

We gather from our American contemporaries that the New York photographers are forming a body with aims very similar to those of the Professional Photographers' Association. A meeting held recently in New York lays forth the activities of the Society, and we may quote the Secretary's invitation to attend for an outline of the programme which the members set before themselves. The officers of the Society are:—President: Pirie MacDonald, 141, Broadway, New York; First Vice-president: Theo. C. Marceau, 258, Fifth Avenue, New York; Second Vice-president: Dudley Hoyt, 23, East Ave., Rochester, N.Y.; Secretary: Walter E. Talbot, Schenectady, N.Y.; Treasurer: Joseph Byron, 53, W. Thirty-second Street, New York.

"On this occasion the Society will take up the question of laying before the Board of Underwriters reasons for a reduction of rates of insurance on photographic galleries.

It is obvious that a large membership will give power to the society in its representation to the underwriters. You will be helping the cause by sending in your application for membership at once. The committee is formulating a report on the copyright situation, as it is to-day, which will be discussed thoroughly at the meeting.

If there is any topic you would like to have debated, or suggestion along practical lines you would like to make, please send the facts concisely stated to the President, and if it is possible the matter will be worked up prior to the time for the meeting. Suggestions will be welcome.

An exhibit of photographs will be arranged and hung by a Committee of Selection" with a view to showing only unique and helpful works. A suitable certificate will be issued to those who are fortunate enough to have any of their pictures hung, and as the works will be very carefully judged, the certificates will have an unquestionable value. No more than six pictures by any one person will be hung.

We want you to be represented. If you care only to send one or two, let them be pieces that you are willing to fight for. Inform the President if you intend sending an exhibit, so that arrangements can be made. Labels and blanks will be sent on application."

Photo-Mechanical Notes.

The Kaiser and Process.

It really looks as if royalty will be showing processmen the way. Last week we read in the "Express" another instance of the Kaiser's versatility, provided by an incident at a recent reception by his majesty of a number of people who had received decorations. Among those received was the managing director of a lithographic firm, with whom the Emperor at once entered into conversation, mentioning a new invention which had already been adopted in England. The director confessed his ignorance of the value of the invention, although he had heard of it, whereupon the Kaiser expressed great astonishment, and recommended the introduction of the patent into German works." The process which the Kaiser recommended, we have been told, was Photo-stone, a method of reducing lithographic labour at the hands of artists' end by aid of the camera, whilst retaining the fidelity to the original.

Perchloride of Iron Solutions.

The following useful table is given in last month's issue of "Le Procédé," by means of which when one has a solution of perchloride

of iron of known strength, according to Baumé's hydrometer, the method of using this is simple. In the first column find the number corresponding to the Baumé hydrometer reading of the strong solution, and follow the horizontal line till it cuts the vertical column at the top of which is the desired hydrometer reading, the number then found will show the number of volumes of the stock solution, which must be mixed with sufficient water to make 100 volumes in all to give the weaker solution of the desired strength:—

which are several apertures of different sizes, the novel feature claimed being the small apertures symmetrically disposed round a central opening. Figure 1 shows one form of the diaphragm. Of the seven apertures, *a*, *b*, *c*, *d*, *e*¹, *e*², *e*³, four, *a*, *b*, *c*, and *d* are circular, and the others segments of a circle. The areas of these apertures are as 5 : 4 : 3 : 2 : 1 : 1 : 1, and all the openings lie within a hexagon, which corresponds to the hexagon marked

Fig. 1.

Fig. 2.

out by the apertures of the focussing diaphragm with a symmetrical point taken between each (Fig. 2). The lens and screen are adjusted by aid of this diaphragm so that the images of the three openings formed by adjacent openings in the screen fall two and two together, and thus a system of evenly distributed dots results. The stop (Fig. 1) is then inserted, and exposure made.

PHOTO-MECHANICAL PATENTS.

Application for Patent.

PRINTING TEXTILE FABRICS (No. 8,046).—Improvements in the production of photo-engraved surfaces for printing textile fabrics. Cyril Joseph Atkinson and the Calico Printers' Association, Ltd., 17, St. Ann's Square, Manchester.

Exhibition.

STIRLING.—The following are the successful exhibitors at the Photographic Exhibition which opened on Tuesday in connection with the Stirling Photographic Club at the Club Rooms, Corn Exchange Square, Stirling:—Champion Class: A. Chapel Milne, Brechin, "The Spate." River, landscape, scenery, etc.: (1) W. S. Crockett, Glasgow, "Twixt Spring and Summer"; (2) Robert Marshall, Grangemouth, "The Sun sinks in the West"; (3) A. W. Hill, Shotts, "Winter Landscape." Portraiture and Genre: (1) P. D. Nairn, Perth, "Auld Sandy"; (2) Robert Thomson, Edinburgh, "The Colourman"; (3) G. L. A. Blair, Paisley, "Portrait of a Painter"; (4) A. W. Hill, Shotts, "The Bo's'n." Lantern Slides: (1) Graystone Hird, Bath, "Landscape"; (2) James A. Taylor, Paisley; (3) Dan. Dunlop, Motherwell. Federation Societies' Exhibits: Brechin No. 2. "Plaque." Landscape, Seascape, and River Scenery (members): (1) John Walker, "The Brook"; (2) Alfred Mathers, "Approaching Winter"; (3) H. S. Turnbull, "A Woodland Glade." Portraiture and Genre (members): (1) J. G. Bowie, "A Reverie." Two prints from photos taken at club outings (members): S. Goudie, "Drip Bridge" and "Alva Glen." Lantern Slides (members): (1) J. J. Munro, Stirling; (2) F. Humphreys, Stirling; (3) J. G. Bowie, Bridge of Allan.

FORTHCOMING EXHIBITIONS.

April 7-May 8.—International Artistic Exhibition, Berlin. Director, Herr Franz Goerke, Maassenstrasse 32, Berlin, W.

April 24-29.—Redcar and Coatham Literary Institute Photographic Society. Secretary, W. Hildrith, 42, Newcomen Street, Redcar, Yorks.

April 27-29.—Southend-on-Sea Photographic Society. Hon. Sec., J. Archer, 24, Ashburnham Road, Southend-on-Sea.

April 28-29.—Watford Photographic Society. Hon. Secretary, C. J. Trevarthen Ashcroft, Bushey Hall Road, Watford.

May 1-31.—International Exhibition of Photographic Picture Postcards, concurrently with the 10th Salon. M. le Secrétaire-Général du Photo Club de Paris, 44, Rue des Mathurins, Paris

May 9-10.—Ballarat Camera Club. Hon. Secretary, G. Montgomery, 201, Sturt Street, Ballarat.

May 9-13.—Warrington Photographic Society. Hon. Secretary, A. C. Smithson, 13, Chester Road, Warrington.

May 10 to June 19.—Salon of the Photo Club de Paris. Secretary, Paul Bourgeois, 44, Rue des Mathurins, Paris

May 18-24.—Coatbridge Photographic Association. Hon. Sec., Geo. W. Campbell, Carnegie Library, Coatbridge.

July 4 to August 12.—Northern Photographic Exhibition. Secretary, F. G. Issot, 62, Compton Road, Harehills, Leeds.

September.—Royal Photographic Society, New Gallery, Regent Street, London, W. Secretary, J. McIntosh, 66, Russell Square, London, W.C.

October 28-November 4.—Sheffield Photographic Society. Joint Hon. Secretaries, J. W. Charlesworth, 1 Joshua Road, Sheffield and James W. Wright, 62, Vale Road, Sheffield.

November 21-25.—Southampton Camera Club. Hon. Secretary, S. G. Kimber, Oakdene, Highfield, Southampton.

December 1-6.—Hove Camera Club. Hon. Secretary, A. R. Sargent, 55, The Drive, Hove.

December 12-20.—Southsea Photographic Society. Hon. Secretary, F. J. Lawton 5, Pembroke Road, Portsmouth.

FORTHCOMING COMPETITIONS.

May 15.—Burrongs, Wellcome, and Co. Money prize for negatives developed with Tabloid Pyro-Metol developer.

May 15.—Warwick Dry Plate Co. Money prizes for prints from negatives on Warwick plates. Open to members of Photographic Societies only.

September.—Kodak. £400 in prizes for results on Kodak products Kodak Ltd., 57-61, Clerkenwell Road, London, E.C.

THE New English Art Club, forced by the demolition of the Dudley Gallery to abandon the quarters which it has occupied for many years, is holding its spring exhibition at Liverpool. The change of locality has not, we understand, affected either the character or the quality of the show. Most of the regular contributors are well represented, and there are works by Mr. J. S. Sargent, Mr. W. W. Russell, Mr. J. L. Henry, Mr. A. S. Hartick, Professor Brown, Mr. Muirhead Bone, and other capable artists which are quite in accordance with the best traditions of the club. The members are decidedly making a bold experiment in going to the provinces after having been established in London for such a long period, but the experiment is by no means unlikely to be justified by its results.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

The following applications for Patents were made between April 10 and 15.

COLOUR PHOTOGRAPHY.—No. 7,557. "Improved manufacture of coloured photographic images." Oliver Imray, Birkbeck Bank Chambers, Southampton Buildings, London, for Meister Lucius and Brünig, Germany.

CAMERAS.—No. 7,626. "Improvements in magazine cameras." Charles Fielding, 81, Lodge Lane, Flowery Field, Cheshire.

CINEMATOPHGRAPHS.—No. 7,556. "Improvements." Harry Hamilton Moon, 18, Southampton Buildings, Chancery Lane, London.

PRINTING PAPERS.—No. 7,693. "Improvements in and relating to the manufacture of gelatine emulsion papers." Ludwig Robicsek, 7, Southampton Buildings, Chancery Lane, London.

APPARATUS.—No. 7,900. "Improvements in photographic apparatus." A. J. Boulton, 111, Hatton Garden, London, for Abbé Antoine, Cardon, France.

COLOURED PHOTOGRAPHS.—No. 7967. "Improvements in coloured photographs and methods of producing same." John Edward Thornton, Altrincham, Cheshire.

MERCURY LAMPS.—No. 7994. "Improvements." Hans Vizgo Siim-Jensen, 7, Southampton Buildings, Chancery Lane, London.

DARK ROOM.—No. 8,017. "An improved portable and folding dark chamber for photographic purposes." Louis Navarre, 6, Lord Street, Liverpool.

WASHING PLATES AND PRINTS.—No. 8,054. "New and improved apparatus for washing and fixing photographic plates and prints." William Hibbert, 139, Dale Street, Liverpool.

ROLL FILM CAMERAS.—"An improvement in or relating to roll film cameras." Leonard Ewart Littlewood, 306, High Holborn, London.

COMPLETE SPECIFICATIONS ACCEPTED.

Specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

COLOUR SCREENS FOR FILMS.—No. 10,951, 1904. The claim is for a packet of three flat films, each with a colour filter of stained gelatine or collodion before it, as required for the three-colour process. The filter is affixed to the film, so that when the latter is changed by any suitable plan, such as that of the "Prenio film pack," the next film is ready for exposure behind its filter. Register marks, for the purpose of readily determining the correct superposition of the pigment prints to be made from the three negatives, may be provided by notches upon the margin of the exposure aperture of the carrier. These notches will naturally be reproduced upon the developed films in exactly the same position relatively to the images projected thereupon by the lens. Or, for the same purpose, perforations, such as punctures with a needle, may be made through the entire series of films, after they are in position in the pack. Joseph Thatcher Clarke, Gayton Corner, Harrow.

FOCAL PLANE SHUTTER.—No. 12,003, 1904. The claims are for a focal plane shutter or other roller blind shutter, the size of aperture of which is altered from the outside of the camera. The specification needs the diagrams, but the first claim is for blind aperture regulating mechanism for roller blind shutters, having the blind in two parts, each mounted on a separate and spring-actuated roller, with tapes to attach the free end of one blind part to an inner

roller located inside of, and adapted to be connected and disconnected from, one of the aforesaid rollers, wherein the free end of the blind part on this last-named roller is attached by separate and independent tapes to a winding roller, independent of the other rollers and adapted to be revolved from the exterior of the shutter case to thereby set the shutter, whereupon the size of the slit or aperture between the aforesaid blind parts can be adjusted to any desired extent. Arthur Lewis Adams, 26, Charing Cross Road, London.

DEVELOPMENT DARK SLIDE.—No. 12,038, 1904. A single dark slide with a detachable back portion, which serves as a receptacle for developer. This development chamber is closed by a sliding door, containing ruby glass, and it is suggested that after exposure the plate should be allowed to fall into the developer, and the upper part of the "dark slide" afterwards removed. William Holden, 55, Stamford Street; and James Schofield, 130, Manchester Road, Roches, both of Mossley.

New Apparatus, &c.

Glossy and Matte P.O.P. Postcards. Made by Cadett and Neall, Ltd., Ashted, Surrey.

In response to the growing demand for postcards with the characteristic features of printing-out paper, Messrs. Cadett and Neall have added these two articles to their manufactures. The postcards, which apparently bear the same emulsion as Cadett P.O.P., tone quickly and with good results in the gold sulphocyanide bath. The postcards are put in sixpenny packets of twelve, with two masks, and are doubtless supplied in packets of larger numbers.

The "Negasys" and "Phosys" files for negatives and prints. Made by Houghtons, Limited, 88-89, High Holborn, London, W.C.

It is presumed that every professional photographer has a system of his own for storing and filing accumulations of negatives and prints. He would probably soon be in a most hopeless muddle if he did not.

The "Negasys" File.

What that system is depends, in most instances, upon circumstances that have arisen during the growth of the business. We are quite sure, however, that, in many instances, existing systems of negative and print storing are open to improvement. The negatives may be ever so carefully stored, and the collection of prints equally well looked after, but in a great number of cases that have come under our observation there is often a deplorable lack of method in the filing and cataloguing arrangements, that has rendered the finding of any particular negative or print a matter of time, not to say of uncertainty. Of the devious way and means employed by

the amateur photographer in storing his hordes of pictorial possibilities, we have little to say beyond the fact that each is a law unto himself, and it is generally an extremely hap-hazard one. The fatal tendency to put off the printing of certain negatives, which are meanwhile "put on the shelf," and the indiscriminate bunching together of the season's output for redistribution during the long winter evenings call for a remedy that, for success in its application, must be at once simple and certain. Messrs. Houghton are, therefore, to be congratulated on having taken the matter in hand; and the "Negasys" and "Phosys" files, for negatives and prints respectively, which they are now placing on the market, will do much to restore order in the workrooms of both professional and amateur photographers. The "Negasys" and "Phosys" files amount to no more or less than the application of the well-known card index and vertical filing system to negatives and prints. The system has been universally recognised by business firms as one of the most reliable and simple substitutes for cataloguing in book form. The "Negasys" file, as

The "Phosys" File.

shown in the illustration, is a simple but well-made box, containing fifty numbered envelopes. Each envelope will take a negative, particulars of which can be added outside. An index card completes the file. The principal advantages of this form of filing negatives is that each box will contain as many plates as an ordinary grooved negative box three times the size. The saving in space alone, therefore, is very considerable. In practical use, negatives can be filed by localities, by subjects, by dates, numerically, or in any other way desired, and guide cards can be used to divide or sub-divide the negatives. With the aid of the index, any negative can be found and withdrawn without touching any other negative. The "Negasys" files can be either built up in a series of separate units, or the negatives may be treated as a complete series, and each box given an initial letter, this letter being also added to the numbers on the envelopes. By this means, any number of negatives can be collected for printing purposes, etc., from various boxes, and afterwards replaced without the slightest confusion. When a great number of negatives are filed, a general card index will reduce the system to the greatest possible simplicity. The boxes are made at present in $\frac{1}{4}$ -plate, 5 by 4, $\frac{1}{2}$ -plate, and whole plate sizes, and range in price from 1s. 6d. to 3s. 9d.

The "Phosys" file is intended to replace the album or any other method of displaying prints that has been yet

advocated. To the professional photographer, this file should especially appeal. For the exhibition of specimens it is likely to be extremely popular; and it is extraordinary that the vertical card index system has not been applied to the purpose previously. Each picture is plainly visible; each one is mounted separately to suits its character; all are as secure as in an album, yet each is always interchangeable, and can be taken out and examined as an ordinary mounted print. There are no limitations to the capacity of the file, as prints can be stored, sorted, grouped, changed, remounted, arranged and rearranged just as circumstances require, yet they can be replaced as before in a very short time. Each print is mounted on an art paper or card mount. These mounts, which are supplied very cheaply, have a small circular hole cut through them at the bottom, and are stacked together in an oak tray. A metal rod passes through the tray and the cards and keeps the mounted photographs in position; but this rod can be easily withdrawn and any one print or prints can be taken out for inspection, or the whole number can be turned back like the pages of a book. The applications of this system are limitless, and, used in conjunction with the "Negasys" files, should form a perfect record of both prints and negatives. The oak cases are extremely well made, and in all sizes. In addition to the separate boxes, Messrs. Houghton apply the system in the shape of extremely well-made boxes and cabinets containing drawers and receptacles for prints of various sizes. These cabinets form handsome pieces of furniture, that will form a pleasing addition to the reception room of any photographer. The quartered oak trays, as illustrated above, to take mounts 6 x 6 in. cost 5s., and the prices range from this amount to £5 5s. for cabinets.

"Bertha" Concentrated Transparent Colours. Made by the "Vanguard" Manufacturing Co., Maidenhead.

To colour or tint the monochromatic productions of the camera, in approximate imitation of the hues of nature, appears to be the desire of every photographer at one period or another of his existence. The Vanguard Company were early to recognise this, and their series of "Bertha colours" for tinting photographic prints and transparencies, have achieved a large measure of popularity, not only by their variety, but for the simplicity of their application. The advent of the picture post-card, and the great increase of other types of work likely to be enhanced by skilful colouring, have doubtless influenced the company in extending the series, and in the supplementary set of colours sent to us for trial such tints as "slate," "brick," and "gold" are included. The entire series now comprises fourteen colours, and this will be found complete enough to meet practically every requirement. The colours are supplied in powder form, and it is only necessary to take up a small proportion of the powder with a moistened camel-hair or sable brush and add it to a little clear water, working it with the brush until a perfectly even tint is formed, or the contents of each little box of powder can be dissolved in an ounce of hot water and stored in liquid form in bottles. The diluted colours are applied very easily to most surfaces, but for P.O.P. it is recommended to work with an alkaline albumen medium. The colours are very pure, and in certain cases can be mixed to obtain other tints. The effect of a print treated with the "Bertha" colours is very pleasing if well done.

A pneumatic bulb of small size and oval in shape is a new introduction with the Altrincham Rubber Co., Mossburn Buildings, Altrincham, by whom it is advanced specially for the convenience of users of small hand cameras. The price is 10½d., or 1s. 1½d. in black enamelled rubber. It is one of some thirty different patterns of bulbs made by the company.

A "small sundries" list, giving particulars of this season's cameras

and a list giving prices, sizes, and descriptions of nearly every plate, paper, and film on the market are the two latest outputs from the publicity department of Jonathan Fallowfield, 146, Charing Cross Road, London, W. The latter list is likely to prove very useful, and considerable time appears to have been expended upon its production. A postcard will bring either or both.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

April.	Name of Society.	Subject.
28	Aberdeen Photo. Assn.	Annual Business Meeting.
29	West London Photo. Society ...	Arranging Exhibition and Summer Programme.
29	Watford Photo. Society	Second Annual Exhibition of Members' Work, &c.
1. May.	Southampton Camera Club	Amateur Photographer Prize Slides.
1.	Exeter Camera Club	Experiences with the Camera in Switzerland. Illustrated. Mr. A. Brock.
1.	Wallasey Amateur Photo. Soc.	The Platinotype Process. Mr. W. Hayes.
2.	Royal Photographic Society.....	Retouching and Improving the Negative. Demonstrated. Mr. Redmond Barrett.
3.	Sheffield Photo. Society.....	Some Experiments in Bromide Toning. Demonstrated. Messrs. G. A. Seed and H. S. Nutt.
3.	Manchester Amateur Ph. Soc.	Printing-out Papers. Mr. F. Higginbottom.
3.	North Middlesex Photo. Soc.	Lantern Slide and Print Competitions. Social Evening.
3.	G.E.R. Mechanics' Institution	The History of Photography. Illustrated. Mr. Alex. Stewart.
3.	Edinburgh Photo. Society	Messrs. R. & J. Beck's Specialities in Cameras, Lenses, &c. Demonstrated. Mr. W. F. Slater.
3.	Cricklewood Photo. Society	Ten Minutes' Paper or Demonstration by the Members.
3.	Everton Camera Club	Flower Photography. Demonstrated. Mr. E. Seymour.
4.	Watford Camera Club	Paper: Dr. C. Lester Leonard.
4.	Rontgen Society	Photochromoscope. Mr. T. E. Freshwater.
4.	London and Prov. Photo. Assn.	

ST. ALBANS PHOTOGRAPHIC SOCIETY.—The annual general meeting of this society was held in the society's rooms in the chemical laboratory of St. Albans School on Friday last. A successful year was reported. Mr. W. J. Armitage was elected president of the society. The Committee for the ensuing year consists of Mrs. C. H. Ashdown, Mr. T. Asquith, Mr. W. H. Coleman, Mr. Stanley Kent, Mr. D. A. H. Lawrence, and Miss Worssam. Mr. W. R. L. Lowe and Mr. W. H. Coleman were appointed delegates to the Affiliation Committee of the Royal Photographic Society, and Mr. C. H. Ashdown was again appointed hon. secretary and treasurer.

ALDERSHOT CAMERA CLUB.—On April 20, a demonstration of carbon printing was given before the members of this club by Mr. Basebe. The lecturer made a number of extraordinary statements, one or two of which we may quote. He claimed four advantages for the process:—1. Rapidity of development; 2. Adaptability to after treatment; 3. Durability; and 4. Range of colour. Under the head of durability, he said, it compared very favourably with platinotype, as while prints by the latter process were known to fade in the course of years, carbon pictures retained their original tints practically for ever. The carbon process was very exacting; it demanded good negatives, "and," said Mr. Basebe, "good negatives are rare to-day; ghosts we have in plenty, but very few really good negatives." But, although in this respect it fell behind the ordinary P.O.P., for by the latter good prints could be obtained from ghostly negatives, the lecturer claimed for his favourite process that by it prints could be obtained in one-third the time taken by the P.O.P. Another advantage claimed, was that by carbon deep shadows could be lightened—an impossibility with practically every other process.

SOUTHPORT PHOTOGRAPHIC SOCIETY.—The fifteenth annual meeting of the Southport Photographic Society was held at the Queen's Hall, Nevill Street, on Thursday evening of last week. Mr. D. E. Benson, the hon. secretary (pro tem.), read the report, which showed a satisfactory and successful year had been passed. The officers for the ensuing year were then elected as follows:—President, Mr. Willis Brunt; vice-presidents, Messrs. J. Lambert and J. S. Dickinson; hon. treasurer, Mr. R. Booth; hon. sec. and librarian, Mr. J. T. Rigby; council, Messrs. D. E. Benson, Dr. Bradley, E. R. Cave, Dr. Hawksley, and Dr. Payne; affiliation delegates, Messrs. D. E. Benson and J. T. Rigby; auditors, Messrs. H. M. Jackson and Woodall.

Commercial & Legal Intelligence

EASTMAN KODAK COMPANY of New Jersey.—The report of this company for 1904 and balance-sheet as at December 31 last have just been issued. The results of the year eclipse the previous records of the company brilliant though they have been. The net profits, after making ample provision for depreciation on buildings, plant, and machinery, amount to £688,484, as against £606,740 for the previous twelve months. Out of this sum dividends of 6 per cent. upon the preferred capital and 10 per cent. upon the common have been distributed, leaving £218,099 to be added to the undivided surplus fund, increasing it thereby to £444,584. In addition to this surplus there are special reserves of £103,436. The financial position of the company is reported as exceedingly strong, its liabilities being only its current trade accounts, amounting to £93,603, while its current assets figure at £2,146,325. Of this latter no less than £1,253,347 consists of marketable bonds and cash on hand. The earning power of the company shows a steady increase, as will be seen from the following statement of annual earnings: Year ending December 31, 1895, £49,656 14s. 4d.; 1896, £122,676 19s. 3d.; 1897, £185,232 0s. 1d.; 1898, £243,232 8s. 4d.; 1899, £335,919 5s. 7d.; 1900, £465,816 0s. 7d.; 1901, £517,347 5s. 5d.; 1902, £564,455 0s. 1d.; 1903, £606,740 8s. 11d.; 1904, £688,484 1s. 9d. The earnings for last year, after paying 6 per cent. upon the preference capital, are equal to over 15 per cent. upon the ordinary shares. It is obvious that when the whole of the resources of the company are commercially employed—there being over a million sterling of money doing nothing—the earnings of the company should be materially increased. The shares have risen lately considerably in value, being now quoted: Preference, 111-115; common, 150-155.

A SINGULAR CLAIM.—At Pontypridd County Court on Wednesday of last week a sequel to the Clydach Vale Colliery explosion was disclosed in a case in which Mr. A. H. Chapman, photographer, Swansea, sued Mr. R. Williams, assistant surveyor at the Cambrian Colliery, for £10 damage to five photographic plates used on the occasion of the pit calamity. It appears that on the Monday after the explosion the photographer visited the colliery, and after he had taken three views the defendant questioned his right to be on the premises. While he was away obtaining permission, defendant exposed his plates, which were in consequence spoiled. Plaintiff further stated that he had been commissioned by the "Daily Mirror" to take the views, for which £1 1s. each would have been paid. For the defence it was contended that plaintiff had no right to be on the premises. Judgment was given for the defendant, but without costs.

MESSRS. Reynolds and Branson, Ltd., 14, Commercial Street, Leeds, have issued a large catalogue of photographic apparatus under the title "Handy Guide to Photographic Requisites." Presumably they will send it free on application.

Correspondence.

- * * Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given
 * * We do not undertake responsibility for the opinions expressed by our correspondents.

THE P.P.A. ASSISTANTS' CERTIFICATES. To the Editors.

Gentlemen,—While I am extremely anxious to meet reasonable criticisms of the certificates scheme, I think it should not be supposed to be incumbent on me to reply to those which would not have arisen had the prospectus been studied with proper care. Your correspondent Pembury Ward, for instance, puts it that our three grades suggest first, second, and third ratings for photography generally. That saps our intention, and the suggestion is not justifiable. Our certificates will indicate that the holder is first rate up to the point he goes, and, moreover, we have provided alternative terms for the grades in "Assistant's Certificate," "Operator's Certificate," and "Principal Operator's Certificate." It is a little careless of him to say "now that official permission has been published," etc., when the publication of the draft prospectus was accompanied with an official invitation to all photographers, employers, and assistants to assist in perfecting the scheme.

Your correspondent R. Russell would be able to answer many of his own questions had he read the prospectus, but those of them which relate to wages have nothing to do with the scheme directly.

"Scot" writes temperately, as before, but is it not a little unkind of him to suggest that the operation of the scheme must be suspended because a matter which affects much less than 1 per cent. of the total number of assistants has been overlooked? I have again to thank him for the spirit of his letter and his recognition of the benefits to be derived from mutual respect on the part of employers and those they employ.

"Assistant," also, I thank for his suggestion. A similar suggestion was fully discussed, and was found to be impracticable in that particular form, but in a modified way every certificate will give the same amount of information as to the particular qualifications of the holder.—I am, etc.,

WILLIAM GROVE,

Hon. Sec.

51, Baker Street, W.
April 24, 1905.

MAKERS' FORMULÆ. To the Editors.

Gentlemen,—Mr. Peake's letter on this subject in your last calls attention to the chaotic condition of our weights and measures, and I do not think that our makers are to be blamed if they follow the common custom; nor are they alone, for one can hardly take up a photographic journal or book without finding sinners in a similar sense.

However, to answer Mr. Peake's specific questions. Without direct experiment it is impossible to state the total bulk of B solution; therefore, putting on one side altogether for the moment the exact weight of the "1 oz." of pyro, it is utterly impossible to tell him how many grains of pyro are contained in the ounce.

With regard to A, I believe I am correct in stating that plate makers invariably mean by "pyro. 1 oz." the commercial ounce bottle, which contains 437.5 gr. Therefore A is not a 10 per cent. solution.

May we not assume, with all due respect to the plate-makers, that the infinity of variations of formulæ arises from a little natural jealousy, and is a relic of the olden days, when every photographer

swore by his own formula, and banned all others? Certainly in the light of the experiments of Messrs. Hurter and Driffield and Mr. Watkins, some such simple expression of formulæ as suggested by your correspondent would be more consistent with our present state of knowledge of photo-chemistry.

A is not a 10 per cent. solution, I contend, because a true 10 per cent. solution is one containing 1 part by weight of the solid in every 10 parts by weight of the solvent, and we do not weigh out our developers, but measure them; therefore, if we wish to make a 10 per cent. solution we must either take such a quantity of the solid as will amount to one-tenth of the total bulk of the solution, or we must multiply the weight of our solid by ten to get the total bulk of our solution. In the case in point, on the first premise, we must, to make 10 oz. of a 10 per cent. solution of pyro, use $(480\text{m} \times 10) \div 10 \text{ grains} = 480 \text{ grains}$. This means, as pyro is sold by the avoirdupois ounce of 437.5 grains, that we must purchase two 1 oz. bottles of pyro, and weigh out 480 grains. Surely the more sensible method is to take as the unit our weight of solid—viz., 437.5—and multiply by ten and make the total bulk of our solution 4,375 fluid minims.

With regard to the conversion of metric into English, I, like your correspondent, have noticed a little confusion in the system adopted by various writers, but it all rests on the chaotic condition of our weights and measures, and the specific formula which Mr. Peake gives may be "translated" in two ways, and I give these in parallel columns, only I have added the "to" in the last line:—

		A.	B.
Hypo	400 gms.	8 oz.	3,840 gr.
Sodium chloride.....	20 gms.	175 gr.	192 gr.
Lead acetate.....	10 gms.	87.5 gr.	96 gr.
Gold chlor. (1 p.c. sol.)	100 ccs.	2 oz.	2 oz.
Water to	1,000 ccs.	20 oz.	20 oz.

The results in A are thus arrived at—if 1,000 ccs. = 20 oz., it is obvious that every 100 ccs. = 2 oz.; therefore 400 gms. = 8 oz., but we weigh our hypo by avoirdupois weight; 20 gms. is the 20th of 400, therefore it is equal to one-twentieth of 8 oz. = 175 gr., 10 gms. must be half 20, therefore we get 87.5 gr. B is calculated in the following manner, if 1,000 = 20 x 480, what are 400 equal to and so on, and I contend that B is correct, and A wrong.

Of course in this particular instance the difference is immaterial, but in formulæ for emulsions the error may be so great as to vitiate the whole thing.

May I point out as bearing on this subject your "Ex Cathedra" par on "Exactness in Formulæ" with regard to the difference between the litre and the 1,000 ccs., that I think the difference should be greater than you state, and 1 millilitre = 1.00016 cubic centimetres? But a still more important point in connection with this purely "academic" difference, is that the "litre" and "millilitre" represent the volume of 1,000 grammes and 1 gramme respectively of distilled water at 4 deg. C. (= 39.2 deg. Fahr.). We English use "litre" and "cubic centimetre" to represent the same weights of water at 60 deg. Fahr. The result of this is that as the 1 gramme of water has a bigger volume at 60 deg. Fahr. than at 39.2 deg. Fahr., our c.c. is greater than the millilitre whereas, according to the Continental system, the actual cubic centimetre has been found to be theoretically less than the millilitre. Practically the whole world standardises at 4 deg. C. We take over a bastard system of metric weights, and standardise at 60 deg. Fahr. but our Imperial weights and measures are standardised at 62 deg. Fahr.!

Query: Ought we not to take into consideration barometrical variation?—Yours faithfully,
Edinburgh.

CHEMIST.

To the Editors.

Gentlemen,—Mr. Arthur Peake in your current issue makes a number of comments on formulae for development which tend to show how necessary it is that we should adopt the metric system of weights and measures as early as possible, and give up the confusing "no system" generally employed.

At the top of page 318 he asks how the formulæ, which are given in English and metric units, are derived. A reference to page 15 of this year's "Almanac" will show him how they ought to be derived from each other; but in cases where makers, or processors, of formulæ give what they consider equivalent numbers you probably left the responsibility with them.

The last paragraph on that page deals with the question in Mr. Peake's third paragraph. I suppose that it would never be able to lay down legal penalties for using language which is liable to misunderstanding, and till it is I fear people will not always exactly what they mean, or specify exactly what they mean, perhaps the following may meet your correspondent's wants.

The sodium sulphite usually employed in photography is the talline form, in which half the weight consists of water; assuming that this is meant in both the forms A and B, then the former would give 10 oz. of solution, and, as regards pyro, would really be 10 per cent. solution, whereas B would measure about 12 oz., or be about 8.3 per cent. Nevertheless, I fancy that most photographers would call both 10 per cent. solutions of pyro. I fear, that this confusion would not be removed by the use of metric units. The only thing to do is to follow the instructions of the author.

As to the reason why writers cannot give their formulæ in the plain way described, it is to be considered that people tell us they find answer, and when that is done it is well to remember the old proverb, and "not look a gift horse in the mouth"! The solution of the final formula is:—

Pyro, 8 oz.; sodium sulphite, 195 gr.; lead acetate, 97.5 gr.; chloride, 2 oz. of a 1 per cent. solution. Make up to 1 pint of water.—I am, Gentlemen, yours faithfully,
 April 20.

J. F. TENNANT.

PHOTOGRAPHERS' ADVERTISEMENTS.

To the Editors.

Gentlemen,—I have been much interested in Mr. Frank Colebrook's witty articles supplementary to my own on the subject of photographers' advertisements, but should like to join issue with him on the point, in that he criticises my suggested advertisements as being too much alike. Upon the question of printing and advertising I am aware that I stand in the same position as Mr. Colebrook does upon that of professional photography—viz., that I am an outsider; but still, I am of opinion that if a photographer writes regularly, and frequently changes the matter of his advertisements, it is, upon the whole, advantageous to retain the one of setting. The Fels-Naptha advertisements now appearing in the dailies, or Messrs. Raines' series on page x. of this journal, are instances of my meaning.

Colebrook cites his friend, Mr. G. A. Atkinson, of Ulverston, as an example for photographers to follow. But is Mr. Atkinson a photographer within the meaning of the act—I should say, within the class for whom my notes were written? I rather think that Mr. Atkinson is a stationer, and did I not write that photographers should have some of the business now in the hands of the stationers?—Yours faithfully,
 W. J. CASEY.

Answers to Correspondents.

* * * All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.

* * * Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

* * * Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.

* * * For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington-street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:

J. Clapperton, 23, Albert Place, Galashiels. Photograph of Mr. J. Bell, aged 10 years.

B. H. Williams, 12, Castle Street, Dudley. Photograph of Dudley Castle Fetes.

B. T. Cornforth, 5, Rock Street, Higher Broughton. Photograph of Burrow Bridge, Bolton.

A. Cowle, Ellwath, Alton. Photograph of Interior of West U. F. Church, Alton.

STUDIO QUERY.—Would you kindly advise me upon the construction of a photographic studio, size to be 26 ft. by 14 ft.? What height amount of glass, side and top, would you recommend for working by a West light only?—KIDDERMINSTER.

We should advise a studio of the "lean-to form," with from 5 ft. to 5 ft. 6 in. at either end opaque top and side. The glass at the side may be, to the eaves, 8 ft., and coming to about 3 ft. or 3 ft. 6 in. to the floor. Bolas' book on the studio and its construction, published by Marion and Co., price 2s., will give you some useful hints.

BACKGROUND MATERIAL.—Can you tell me where to get canvas suitable for backgrounds, and the best method of preparing it?—C. FINEX.

The best material for the purpose is unbleached sheeting. It may be had of any of the large drapers up to about 8 ft. wide—perhaps wider if required. To prepare it, strain it on a frame and then give it a good coating of size, such as is sold at the oilshops. It will then be ready for distempering or for flattening in oil.

STAMP PORTRAITS.—1 Would you kindly inform me how to work "stamp photos" cheapest from one negative; size 1½ in. by ¾ in.? I believe these are printed on Velox; but how is it washed quickly—say, about twenty-four on a sheet without expensive apparatus? 2. I have also to copy a good many faded and discoloured photographs for enlarging. How is the best negative of such obtained?—C. O. B.

1. If you wish to work from one negative you will require a special printing frame for the purpose. These frames are supplied by all the large dealers such as Marions, Fallowfields, Houghtons, and others. You will see by our last issue that Messrs. Sharp and Hitchmough, Dale Street, Liverpool, have just issued a new price list of stamp photograph accessories. Better write for one. The prints are washed in the usual way. 2. If the photographs are very yellow the best results are obtained on orthochromatic plates.

COPYRIGHT.—I have taken views of village for photo post-cards, and supplied shop for sale of them. Another shopkeeper bought three of them, and has had them reproduced. I have just had them copyrighted after finding out he was selling same. He is selling them after I have got them copyrighted. Kindly tell me if I can stop him selling, and what claims I can have against him.—M. D. M.

You can stop the sale of further copies, but you cannot

make a claim for infringement of copyright before registration. You may, however, write the firm asking them how they propose settling the matter.

R. W. J., London, N.—Dr. C. L. Marquart, Benel-an-Rhein.

ENLARGEMENTS.—1. What lenses do you consider the best for enlarging? Would an Aldis Series II. be suitable? 2. Would a sheet of opal be as good as a mirror for a reflector outside window? 3. Can you tell me how to avoid hair markings and fine scratches on enlargements, when made with the enlarging lantern? I find the slightest marking on the film of negative are exaggerated a dozen times on enlargements. The enlarging apparatus is incandescent gas.—LANTERN.

1. Yes, an excellent lens for the purpose; and so is almost any reputable maker's anastigmat. 2. We should prefer the opal, it is a better light diffuser; though a mirror will shorten exposure somewhat it is more liable to illuminate the negative unevenly. 3. Only by sacrificing a little of the definition and using a rough paper. But the negative should be retouched, and the enlargement as well, if necessary.

IDENTIFYING LENS.—I bought a Dallmeyer's lens, Series II., No. 4, and gave £6 10s. for it, second-hand. I am told by a friend that each glass should be marked on the edge with the name. Mine has not got it. I should like to know if it is genuine. The mount is engraved "J. H. Dallmeyer, No. 4, London, Stigmatic Series II., Patent No. 67,066."

It is not Messrs. Dallmeyer's practice to mark the glasses in this way. With the exception of one lens, each glass is burnished in. If you are in any doubt, the makers would tell you if the lens is genuine or not on your bearing the cost of carriage each way; and we believe nearly every other lens-maker will do the same.

MOUNTING ON CELLULOID.—Kindly let us know the best method of sticking celluloid to photographs. This celluloid is becoming more extensively used, and we have no doubt it would be useful to many more of your readers to know how to stick it to their prints.—H. and M.

Dip the prints in alcohol and press through a hot press with the celluloid. This is the method used by the "photo-button" maker. If you write Mr. Jonathan Fallowfield he will send you prices of suitable roller presses.

RETOUCHING AND OPERATING.—Kindly give your opinion of (1) the retouching and (2) operating of enclosed photographs, and state where same might be improved.—IMPROVER.

1. The retouching on the young faces is very good indeed—natural and clean; but the high lights might have been increased, and the width of the heavy shadows better graded. The work on the three women is too mechanical, although, from a stippling point of view, nice enough. A softer and looser touch might be cultivated with advantage, especially for the matt papers, with greater ease and freedom from the wrist for the pencil movement. Broader and better blended touches would have suited these faces. You do not send prints made before retouching, so it is impossible to criticise the main features in this important branch of photography—the preservation of the likeness. The work is much above the average we usually receive. 2. Your straightforward work is apt to be hard, we think. Lighting is good usually, but your negative apparently is not right for the printing paper. Your studies, the narrow print of the girl and the circle of the child, are creditable, but we would caution you from letting your taste for this sort of thing—which, we will say, is pretty good—lead you to eccentricity.

COPYRIGHT.—I photographed a nobleman, now deceased, giving him a few copies, which he acknowledged. Others he bought. The

photograph was not registered until a few days after the nobleman's death, and now I am challenged by a person that he can use any of these photographs without my permission for the reason that I had sold copies before registration. Is this so? No money was paid me at the time of sitting in any way; the nobleman giving me the sitting freely, knowing I should benefit by the sale of it.—MODU.

The copyright is not lost to you by the sale of the copies but you should have obtained the assignation to yourself of the copyright by the sitter at the time of the sitting, registering the copyright at the same time. However, the only question is whether the copyright belongs to you or to the family of the deceased sitter. Certainly the photograph cannot be copied without permission.

BACKING.—Can you give me an easily made formula for backing panchromatic plates, preferably with caramel?—T. WHITE.

There are plenty of excellent backings obtainable commercially, and most if not all are suitable for panchromatic plates. If, however, the following be made up, it will answer:—Crystalline caramel, 1 oz.; water, 5 drachms; methylated spirits, 3 drachms; add enough methyl violet, and very little is required to make the mixture black, or some ordinary lamp black may be incorporated with the above. The main point is to have the backing mixture as nearly black as possible.

STRIPPING WITHOUT FLUORIC ACID.—Is it possible to strip the film from negatives without using fluoric acid, which I cannot get.—PHOTOMECHANIC.

There ought to be no difficulty in obtaining hydrofluoric acid but it is nasty stuff to keep and handle. If, however, the plate is soaked for a few minutes in: sodium or potassium fluoride, 100 grains; water, 1 oz.; hydrochloric acid, 10 minims the film will readily strip. A celluloid or papier mâché dish must be used for this, and it must only be mixed just before use.

FRAUDULENT Dundee Canvasser.—At the Dundee Sheriff Court last week the credulity of certain Dundee people, who had been swindled out of small sums of money by a fraudulent canvasser, was brought to light. The case was that of George Hutton Middleton, a canvasser in the employment of the Anglo-Parisian Artists Photo Company, 134, Nethergate, Dundee, who admitted having committed eighteen acts of fraud, the sum involved amounting to £13s. 9d. It appeared that Middleton's duties consisted in soliciting orders for photographs, and on securing a customer he was instructed to leave a card, for which he received sixpence, representing his commission on the transaction. Accused, however, had persuaded several persons to give him more than sixpence. A sentence of four months imprisonment was imposed.

* * NOTICE TO ADVERTISERS.—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

EX CATHEDRA.

Photograph Collecting. An interesting article by Sir Martin Conway on the subject of photograph collecting appears in the current number of the "Grand Magazine." The author discusses the collecting instinct inherent in almost every human being, and in view of the enormous activity of photographers in this country, deplores the annual destruction of numbers of photographs of real importance to the future historian and student of art. He suggests that properly classified collections of photographs undertaken, not necessarily by photographers, would prove as great a source of pleasure as collecting stamps, buttons, tobacco pipes, shoes and gloves of celebrities, snuff boxes, etc. Photographs of bird and animal life for instance, classified series of modern scenery apart from its pictorial interest, reproductions of works of art, portraits of well-known people, photographs of buildings, street scenes, chronological illustrations of a man's life, including his friends, places he lived in or visited, etc., and many other forms that such collections might take are suggested. In addition to this, the formation of an historical photographic museum for the storing and preservation of camera records of existing objects of beauty and interest is proposed. We are quite in accord with these statements on the whole, but surely Sir Martin Conway cannot be cognisant of the extensive labours in this direction of Sir Benjamin Stone and his ever-increasing contributions of photographs of men, manners and matters to the British Museum; of the good work accomplished in the same direction by the National Photographic Record Association, and the innumerable photographic surveys now being energetically undertaken in all parts of the kingdom under the auspices of various photographic societies, to say nothing of the newly formed Arundel club, which has for its object the collection and publication of

photographic records of works of art. Apart from this, however, we think that the idea of photograph collecting by the individual, as a hobby, is a good one, and if carried out as systematically as, say, stamp collecting, would be both interesting and profitable.

* * *

Second-hand Photographs. In the same article, Sir Martin Conway remarks that although multitudes of people buy photographs, very few as yet buy and arrange them methodically, and, therefore, commercial organisation for photograph collectors does not exist, and, further, "that no trade is alive until the articles it supplies have a second-hand value. It is by the second-hand trade that the health of a business in new objects can be tested. The fact that some books are worth far more second-hand than when they were new, the fact that some pictures increase in value from year to year, that some postage-stamps grow more valuable as time goes by, stimulates the collection of such objects, and gives vitality to the trade in them." The recommendation for dealers in second-hand photographs for collectors is a novel idea; but, first, the advent of the ubiquitous photographic picture postcard has to be taken into consideration; secondly, the increasing value of photographs cannot possibly bear comparison with objects the issue of which has been ascertained and is finite, unless the original negatives are not in existence; and, thirdly, the author appears to have overlooked the fact that until photographs are produced that can be guaranteed to have a uniform degree of permanence, second-hand prints are not likely to have an extensive market, and cannot, therefore, be compared with stamps, pictures, or books, etc. which have a reasonable chance of long life.

The Trade in Photographs.

The trade in photographs is in a very indifferent condition in England, according to the writer referred to above. He says that "no trade is so badly organised as that of photographs," but holds the Italian photographic view trade up as a brilliant exception. Italy is apparently the only country where the production and sale of photographs has really been carried to a high degree of perfection. With the catalogues published by the chief Italian photographers at hand it is easy for anyone to order and obtain photographs of almost any kind of view or work of art existing in Italy. England appears to be at the other end of the scale—the country in which photographic publication is least efficiently carried out. "The moment anything outside the most commonplace range of tourists' photographs is wanted in this country, it is almost impossible to obtain it," says Sir Martin, who also states that there is room in England for several great photographic publishers to cater for the demands of the large touring public, and still more of the public that seldom tour, but desire to possess repre-

sentations of objects they cannot travel to see. The writer's pronouncements in this respect should be authoritative, but we would have thought that the output of such firms as Frith, Valentine, Hanfstaengl, Erdmann and Schanz and other well-known publishing houses, to say nothing of the vast number of views and reproductions of works of art in postcard form that are published almost every week might have saved this country from the denunciation of the eminent explorer.

* * *

Wet Weather Photography. Probably no period of the year is better suited for the production of "wet weather" photographs than the present. By wet weather photographs we mean representations of familiar views, usually street scenes, taken during or immediately after a shower of rain. Earlier in the year is not so suitable for the purpose, as the light is not then so actinic, nor are the conditions nearly so favourable for the work as at the present time. The pictorial possibilities of this type of outdoor work has been made familiar in this country by the pictures of John Beeby and others. Gleaming pavements, dripping trees, scurrying figures with mackintoshes and umbrellas, and wonderful reflections, not only provide good material for the hand camera man, but present well-known streets and places in an altogether new guise. When rendered in the form of picture postcards, they have a ready sale, which leaves the ordinary portrayal of the same views far behind.

* * *

Hand Camera Work in the Rain. Heavy showers, with intermittent gleams of sunshine, afford the best opportunities for this work, and the present time of year is particularly fruitful in climatic vagaries of the sort. Sunshine and rain together also give striking effects, and as these photographs depend chiefly for their novelty and beauty on the reflections, points of view should be chosen, showing good stretches of wet roadway or pavement. The paved sidewalks in many towns are bordered with trees, and a vista of these—now in spring raiment—will help a composition of moving figures, while it will frequently be found that what would be quite a commonplace street scene in dry weather has been converted by the aid of a passing shower and the subsequent reflections into a very effective picture. Exposures from 1-20th to 1-100th of a second can be given, according to the amount of movement present, and fully-exposed negatives can be obtained with a focal-plane shutter giving higher speeds, as there is always a great amount of light reflected from the ground. Fast, backed plates should be used, and, of course, it is essential that the lens should be protected from any stray rain drops. A before-lens shutter and a box-form camera will probably be found most useful on this account, but otherwise, if the photographer decides to brave the elements during the shower, he can always work in comfort under an umbrella held by a friend, although good results will not be so readily obtained as immediately after rain, owing to the blurring of the reflections by rain dropping on the pavements.

* * *

The New Chemistry. This week commences a short series of articles from the pen of Mr. Kenneth Mees, for which we need offer no apology, though we will not deny our less scientific readers a word of explanation. Take up the current journal of any chemical society, and you will find half the papers full of terms and language which are so much Greek to the chemist who left his classroom, say, even ten years ago. Physical methods of investigating phenomena have brought in their train a set of new expressions—the shorthand of your modern

chemist, but unintelligible to the student whose textbook days ante-dated the new movement. Yet the commonsense of this modern chemistry is not beyond the grasp of the average student, and in putting him in a way to understand it, we are simply following our own precedents of many years. The chemistry of photography has always received a fair showing in the *BRITISH JOURNAL*, and such a series of papers as that which Mr. Mees here begins has impressed us as particularly necessary, if those who have hitherto followed chemical progress are to maintain an intelligent interest in chemistry, and particularly in photographic chemistry.

* * *

Chemical Technology of Japan.

Professor Otsuki, who read a paper before the Society of Chemical Industry on Monday evening, is a Japanese member of that almost international body, and for some time past has been prosecuting researches at Hanover. Dr. Divers, the first professor of chemistry at Tokio, and the man to whom Japan owes her first enlightenment in chemical science, referred to the aptitude shown by the Japanese science student, and as proof of his statement came the announcement that Japan founded her own Society of Chemical Industry a year ago, and now has a thousand in its membership. With young Japanese in almost every university and technical school in Europe, it is well to consider the probable immediate future of chemical manufactures in the island empire of the East. Photographic manufacturers, in particular, may well ask how long it will be before Japan will be making herself independent of Western supplies of photographic material. At present several British firms number Japan among their important customers, despite the difficulties of delivering goods so far from their factories. Yet no one can imagine that competition with the Japanese maker in his own market will not come sooner or later, though the reputation of English plates and papers will lay heavy burdens even on our clever and versatile allies.

* * *

The Action of Peroxide of Dry Plates.

Since Dr. Russell's researches on the production of a latent image on gelatine plates by the chemical action in the dark of certain substances, a good deal of experimental work has been done in this sphere of "photography without light," vapography or radiography as it has been variously styled. In the present state of our knowledge we prefer the term "pseudo-photography," under which the miscellaneous effect, resembling those of light can be classified. It is still a debatable point whether the various bodies which produce a latent image in the gelatino-bromide emulsion do so by direct chemical or by a species of radiation, and the paper by Professor Chiri Otsuki, Ph.D., last Monday evening, before the Society of Chemical Industry still leaves room for discussion. The author confined himself to a "Study of the Action of Hydrogen Peroxide on a Photographic Plate in the Dark," and he concludes in favour of direct transmission of hydrogen peroxide vapour to the film. The chief reasons for this belief are the destruction of the image by the action of plain water for an hour, and the fact that while action of the peroxide is exerted through gelatine, celluloid, etc., in no case could it be made to pass through metal, except the latter was actually perforated by the peroxide.

* * *

Theories of Pseudo-Photography.

The vapour theory has always seemed to us a very difficult one to support, in view of the sharp reproductions of objects which have been obtained—Dr. Otsuki showed some

remarkably good specimens—and of the fact that certain media which appear to transmit the action are not directly permeable by the vapour. Dr. Russell recognised this difficulty and Mr. Chapman Jones suggested some years ago that the radiation, if such it be, is produced by the strong oxidation of the peroxide. Prof. Otsuki confirms Graetz's observations that differences of temperature between the peroxide and the plate exercise an enormous effect on the character of the action. For the present, it appears, judgment as to the true cause of the phenomenon must be reserved.

The Picture Season.

Spring commences the picture season. The Royal Academy Exhibition is now open, so is that at the New Gallery, to say nothing of the numerous minor shows in London. On the Continent, in all the principal cities, the annual exhibitions of pictures are open, or will be during the next two or three weeks. So far as the Royal Academy show is concerned the general opinion is that it is a fairly good average one, and nothing more. We learn that something like a thousand pictures sent in were rejected, to the sore disappointment of hundreds of aspiring young artists. This is also the season when fine-art publishers are on the look-out for securing the right of publication of such pictures as they think will command a good sale. At the present time we know that more than one of the largest continental art-reproduction houses have representatives in this country with that object in view.

A Photographic Historian.

There is a professional photographer in Seattle, in the North-west of the United States, who has made a name for himself from work done in hours when he has not been earning his bread and butter. His name is E. S. Curtis, and his hobby for years past has been the photography of Indian tribes. Appreciation takes the shape of an article in "Scribner's," and a public exhibition of his work at the Waldorf-Astoria, New York. In possessing himself of probably the best collection of Indian pictures, Mr. Curtis has cast aside the ordinary comforts of life, and spent a large proportion of each year on the most fatiguing journeys, extorting sittings from the reluctant Indians, who either over-rate the value of their services, or shrink from the "devil-machine." Mr. Curtis works in gum and multi-gum and is reported to be sending his photographs to European exhibitions this year.

Celluloid Dangers.

Not long ago we referred to certain alleged cases of spontaneous inflammability of celluloid, and since then there has appeared from the Home Office a cautionary circular as to the handling and storage of celluloid in manufacturing premises. An extract from these regulations appeared in our issue of March 7 last. That attention should need to be drawn to the inflammable nature of celluloid is almost a matter for surprise, but that such is the case we cannot doubt. Cinematograph accidents are not the only ones. Our readers will recollect the lamentable fire in Queen Victoria Street, the cause of which was celluloid. Now we hear from the Berlin correspondent of the "Daily Telegraph" that recent accidents there have moved the authorities to frame special regulations. That fact alone need not arouse consternation, for it is difficult to imagine any sort of accident too small for a German official body to make the *raison d'être* of a set of regulations. However, a catastrophe actually occurred last Friday. A boy was lighting some packing in the yard of a fancy warehouse

where celluloid goods were stored. Apparently some waste pieces of celluloid were in the rubbish, for suddenly flames shot up, the fire spread to the celluloid stock, and a series of explosions followed, smashing all the windows of neighbouring houses and injuring the passengers on a passing electric car. Obviously, the case is one of culpable carelessness; but that, unfortunately, does not deprive celluloid of its dangerous character.

Where Ignorance is—Danger.

Considering the many uses to which celluloid is now put, and its highly inflammable nature, it is a matter for congratulation that there are so comparatively few accidents. For when the material is once alight it cannot be extinguished, and it will burn itself out in a few seconds. What is most surprising is that those who make the greatest use of celluloid fancy articles are, as a rule, quite unaware of its dangerous character. Ladies, for example, who wear "tortoise-shell" combs, hair fasteners, and such-like things, have no idea of the danger they may run. Showcards are now being made of celluloid, and we recently saw one hanging in a restaurant in close proximity to a gas flame, the proprietor being evidently unaware of its dangerous inflammable character. As we have just said, it is a little surprising that there are not more accidents than there are. There is no question that a large addition of pigment to celluloid greatly reduces its inflammability and easy ignition. The celluloid, or xylonite, of which photographic dishes are made is not so inflammable as is the more transparent material such as is used for artificial tortoise-shell.

"Antioxydants." It has always been an accepted axiom, at least, since the eighties, when Berkeley suggested its use, that sodium sulphite was employed in developers to prevent the oxidation of the developing agent, but this view is controverted by a recent research of MM. Lumière and Seyewetz, who prove that the addition of certain developing agents to sodium sulphite solution prevents the oxidation of the sulphite. The original paper is filled with tables and curves obtained from their quantitative analyses, but the practical conclusions they come to are—that weak solutions of sodium sulphite may be kept, without oxidation, for a long time by the addition of very small quantities of these "antioxydants." About 0.75 grammes of paramidophenol hydrochloride, 0.3 grammes of hydroquinone, or two or three grammes of trioxymethylene (paraformaldehyde) per litre of 3 per cent. solution of sulphite practically prevent the oxidation of the same. As to the theory involved the authors are not certain, though they point out that sulphite *per se* and developing agents *per se*, though rapidly oxidising in aqueous solution, yet do not do so when mixed. They describe the action as probably "diastasic" or "catalytic."

Formaldehyde in the Air.

Several French chemists have recently shown that formic aldehyde, the active constituent of the photographer's "formaline," is a constant constituent of the air of towns. Some further experiments by M. Trillat recently communicated to the French Chemical Society prove that the formaldehyde is produced by the incomplete combustion of a great number of materials, including wood, paper, coal, peat, and petroleum. The quantities formed are not so very small, coal yielding 1.4,000th of its weight of formaldehyde on heating in an iron stove. As an idea of the quantities thus discharged

into the air, the following figures of M. Trillat's may be used:—

Air taken	Formaldehyde per 100 gals. of air.
On roof of Pasteur Institute18 grains.
Half-way up20 grains.
At Courbevoie (outside Paris)4 grains.

In detecting the formaldehyde, M. Trillat employed porous paper containing para-rosaniline hydrochloride, the paper becoming blue in the course of an hour or two when formaldehyde is present. His results have certainly a photographic interest, as the presence of even such minute quantities of formaldehyde in the air may have an effect on gelatine plates and papers.

Poison Bottles.

The question of a special shape of bottle for poisons has again arisen from some recent cases where fatal results have attended mistakes in the contents of the bottle. The suggestion has been made before, and several types of bottle put forward for the purpose. If our memory serves us, one of the London evening papers deprecated the adoption of a bottle constricted round the middle to the contour of a fashion-plate young lady on the ground that its very object would be defeated; the average man, by habitual association of ideas, would pass from clasping the waist to pressing to the lips! But in view of accidents which constantly take place, it would be well if a special form of bottle could be recognised under the Pharmacy Act. It would be one great factor in the prevention of accidental poisoning.

Scheduled Poisons.

The number of poisons which can be sold only by a certificated pharmacist are comparatively few in numbers, and of course the list does not include many substances which are dangerous poisons. The scheduling of carbolic acid is stated to have materially reduced the number of deaths from that poison, and now the dangerous mineral acids and ammonia are mentioned as advisable additions to the list of scheduled bodies. The pharmacy regulations are curiously inconsistent in what they do not schedule. For example, mercuric chloride (corrosive sublimate) is a scheduled poison, but mercuric iodide is not, and even when reforms have been made in the retail sale of poisons, there still remains the anomalous condition of things under which anybody can freely purchase the most deadly poisons in large quantities.

PORTRAITURE AT THE ROYAL ACADEMY.

WE have on previous occasions taken the opportunity of drawing the attention of our readers to the advantages derived from a study of good portrait-paintings by artists of repute. Not only are these productions of the brush likely to inspire camera portraitists with many new ideas in the way of pose, lighting, arrangement of accessories, composition, etc., but the outstanding qualities to be observed in the treatment of expression should prove an object-lesson to many professional photographers. This year's Academy, which opened its doors to the public on Monday, is particularly rich in portraiture, and although, as is usually the case in each succeeding exhibition of the R.A. at Burlington House, there are many specimens of portrait and figure work that had better not be taken as examples to follow, much that is exceedingly good in every respect is to be seen on the walls. The genius of J. S. Sargent is displayed to the full in the six examples of his work on view. His magnificent portrait of "Señor Manuel Garcia" will repay much careful study. As an example of concentration it would be hard to beat. The material

is summed up with an extraordinary simplicity and force, wholly suitable to the subject and the occasion. The strong, almost mysterious, face of the centenarian is dealt with in a manner that ought not to be beyond the capacity of the camera should the occasion arise to portray a similar type, but in particular are the sensitive, yet "old," hands worthy of close attention. The posing of the hands is a subject that receives far too little attention from the average portrait and figure photographer. There are, of course, notable exceptions whose treatment of this part of the human figure frequently brings forth the comment, "How painter-like!" These workers have probably studied the results achieved by masters in painting, and applied them in practical use. The portrait studies by A. Hacker in this year's exhibition are therefore worthy of careful inspection and study, if for this reason alone. His portrait, "M. H. Spielmann, Esq.," disposes in a clever manner of the difficult subject of a man in evening dress examining a portfolio of prints. The masses of light formed by the face, the white shirt-front, the hands, and the prints are dealt with in a manner that leaves very little to be desired. Again, the sitting figure, "E. S. Phillips, Esq.," gives a suggestion for dealing with somewhat awkward academical robes and "mortar-board." The pose of the hands in this picture is remarkably happy, as also is the case in W. W. Oules's "Thomas Pilkington, Esq." In fact, in nearly every notable portrait in the present show in which the hands are included, the power of expression that can be conveyed by these useful members is made full use of, and in practically every instance could be taken as a useful guide by the photographer when dealing with similar subjects.

The portraits of ladies, too, are very plentiful, and the arrangements of draperies, skirts, lace, and other frou-frou should provide much mental pabulum for the ambitious portrait photographer. The numerous groups displayed, particularly those by J. S. Shannon, J. S. Sargent, and S. J. Solomon, afford striking examples of what to do when dealing with more than one figure in making a pleasing composition, although, it will be noticed, in many cases, a practice frequently decried in professional photography is seen, namely, that every member of a group is staring straight at the beholder.

The proper treatment of the background is often the fault in many otherwise successful photographic portraits. Here, again, a study of the methods of the leaders in the painting world will prove of enormous assistance. J. S. Sargent, for instance, in most of his striking single portraits relies on the effect and relief afforded by an extremely dark, plain background—almost black, in fact. This not only tends to strengthen the face and figure of the sitter, but the gain in simplicity and forcefulness is undeniable. In the portraits by W. W. Oules, Seymour Lucas, Solomon J. Solomon, A. S. Cope, James Sant, Arthur Hacker, and others, the same concentration of light and effect on the face is to be seen, and the background in nearly every example is made dark and plain. Professional photographers are, however, beginning to realise the great gain to be effected by simplicity in backgrounds, and the tendency of late to substitute plain dark grounds, or with very little gradation, is being appreciated by a public that is quick to institute comparisons between paintings they can enjoy and photographs they do not.

The Royal portraits this year are also very plentiful, and will give a clue as to what treatment glittering raiment, uniforms, and jewels should receive. Quite apart from the blaze of colour exhibited in Luke Fildes's "command" picture of Queen Alexandra, or Harold Speed's fine full-length portrait of the King, and A. S. Cope's "The Kaiser," these fine efforts are again, in spite of the mass

of detail present, remarkable for their concentration, both in lighting and composition.

The question of clothes is always a difficult one in portraiture, and our contemporary, the "Tailor and Cutter," will doubtless have a word or two to say, as usual, on the badly fitting, and in some cases almost impossible, habiliments of some of the gentlemen and ladies depicted on the canvases at Burlington House. We are not altogether sure, however, that painters are not right in sacrificing everything for the portrait, or, at least, in not unduly bringing into prominence the productions of the tailor and milliner, and it is undoubtedly true that many famous artists are equally famous for their disregard of the current modes. The mould of form satisfies them; with the glass of Fashion they have nothing to do; and although inaccuracies in the cut and finish of gowns, buttonless coats that would rend the heart of any tailor with self-respect, and trousers that he would have refused to cut, are to be seen here and there, the fact is immediately lost

sight of in the contemplation of the sitter's personality that shines forth from the "tout ensemble" of the portrait itself. This is as it should be. The portrait is the thing, and the more photographers there are who grasp this fact, and assist themselves by the study of the year's best paintings, the better it will be for their popularity, to say nothing of the effect on their output.

To those photographers who are unable to pay a personal visit to the Academy we can recommend the several excellent illustrated catalogues that are published. These reproductions in monochrome will probably be of almost as much value to the photographer as an inspection of the original pictures. The absence of colour will accentuate the presence of form and line, and the composition will, in most instances, be more readily grasped. If, however, a visit is made, the collection of portrait miniatures in the Water Colour Room will repay attention, and give much valuable assistance to those who produce this sort of thing with a photographic base.

MODERN CHEMISTRY FOR PHOTOGRAPHIC WORKERS.

INTRODUCTORY NOTE.

In the course of the last ten years there has arisen in the chemical world an entirely new force, modifying the older conceptions, and changing the language of the science. And the results of this new force are so far-reaching, and at present so little developed, that we may look for an outburst of new life in every branch of chemical technology, as the applications and modifications thus introduced are realised. This modern chemistry is generally known as physical chemistry, because it has adopted methods of investigation which were formerly employed almost entirely in physical experiments, and, moreover, it uses the language and mathematical formulæ of the physicist.

The point wherein, however, physical chemistry differs from the chemistry which was formerly so thoroughly developed, is that whereas the earlier chemistry deals with the products of reactions, this modern chemistry deals with the course of the reactions themselves. It is, for instance, sufficient for the chemist of twenty years ago to know that silver bromide can interact with thiosulphate of soda to give a soluble silver sodium thiosulphate; the physical chemist wants to know in what way—that is, how fast, and under what conditions, this reaction can occur. And there is probably no branch of chemical technology in which more advantage is to be gained by the introduction of the methods and conceptions of physical chemistry than that grouped under the general name of photo-chemistry, so considerable a portion of which deals with the reactions and phenomena exhibited by the substances used in photography.

The rise of physical chemistry has, however, been so exceedingly rapid that probably the majority of modern chemists had left the class-room when it was still unknown, while it is a curious but indubitable fact that the conceptions of physical chemistry are generally supposed to be exceedingly difficult to comprehend. The cause of this is two-fold. In the first place,

mathematics is supposed to play a great part in physical chemistry, and many a good photo-chemist regards mathematics with a horror second only to that which he reserves for "green fog." In the second place, really good books in English on physical chemistry have been issued only during the last few years.

The second difficulty has now been met, while the mathematical bogey need scare no one from using the non-mathematical portions of physical chemistry, which are by no means the least important. To avoid the physico-chemical methods because mathematical physics is beyond one is like refusing to use a lathe because it is not fitted with an automatic turret; the mathematics will be most useful if they can be acquired; but non-mathematical physical chemistry will prove an exceedingly valuable tool.

And it is with a view to placing some of the physico-chemical conceptions and methods before photographers in such non-technical and simple language as may be possible that this article, and those that follow, have been undertaken. The series will deal in some manner with the following subjects:—

I. The properties of solutions and their relations to gases: osmotic pressure.

II. The ionic theory and dissociation.

III. The application of the ionic theory to chemical reactions.

IV. Equilibrium and the final result of reactions.

V. The velocity of reactions: chemical dynamics.

Much use has been made of "Modern Chemistry," by Sir William Ramsay, published by Dent and Co., and of the series of text-books of physical chemistry edited by Sir William Ramsay, and published by Longmans and Co. The thanks of the author are due to Sir William Ramsay for his permission to use these books.

AND THEIR RELATIONS TO GASES: OSMOTIC PRESSURE.

Conceptions of Physical Chemistry.

It is frequently urged against the physical chemist that the conceptions which he chooses to employ are purely hypothetical imaginings, of which he cannot prove the actual existence. And to this he will most cheerfully assent, merely pointing out that the same statement applies to all other scientific conceptions. No one ever had proof of the existence of an ion any more than

any one ever had proof of the existence of an atom or a wave of light; both the ion and the atom are hypotheses which were invented, and are used, in order to group series of phenomena under general headings, and the value of a hypothesis depends on the power of grouping phenomena which it may exhibit. The question as to whether an atom or an ion really has any objective existence is not of scientific, but of metaphysical, interest.

What is a Solution?

Now, since physical chemistry employs physical methods for the investigation of reactions, the physical state of the reacting bodies is naturally of great interest. The reacting bodies may exist in any one of four physical states, as solids, liquids, gases, or in solution. And before we can develop any facts about the reactions, we must get conceptions as to the meaning of these physical states, and especially the exceedingly important one of solutions.

Suppose that we take a small quantity of sugar and examine it, we see a number of small white, shiny grains. We add it to a quantity of water, and shake it for a minute, and the white grains are gone, leaving the water clear as before. Now, what has happened? Clearly the sugar has distributed itself throughout the mass of the water in some manner. And now we want to find the condition of our former white sugar in the bulk of the water.

There is only one state in which we have observed so small a mass of substance as our sugar to occupy so great a bulk as that sugar now occupies, and that is in the state of gas, so that it is clearly to the gaseous state that we must turn for an analogy to our sugar solution.

Gases and Solution.

The most obvious property distinguishing gases is the readiness with which they change their bulk upon the application of pressure. If we take a quantity of gas and confine it in a tube by filling the lower end of the tube, and also another tube attached to the lower end, with mercury, we shall find at once that by pouring more mercury into our tube, and so increasing the pressure on the gas, we can greatly diminish its volume. And by conducting this experiment in a properly graduated apparatus we can very easily show that if we double the pressure we halve the volume, so that if we multiply the pressure by the volume, the product is quite constant, which at once gives us what is known as Boyle's law—namely, that the volume of a gas varies inversely as the pressure.

Gas Pressure.

If we look for a minute at our apparatus, when we have increased the pressure on the gas and correspondingly diminished the volume, it will probably occur to us to wonder what it is that is resisting the pressure which our mercury is causing. Well, Boyle called it "the spring of the air," and pictured air as being a sort of hair mattress containing a great number of little invisible curly springs. But since we shall find it convenient to consider all substances as made up of a very great number of little molecules, we must clearly try to get our picture of what resists the pressure from that conception. Now, if we take a ball and throw it at a ninepin, the ninepin is knocked down without further ado by, as we say, the force of the blow; and this force depends on two things: the one, the weight of the ball, and the other, the speed with which it was moving. Suppose that instead of that ball we took one only one-hundredth of the size and threw it at our ninepin, we should probably have failed most completely to knock it down; but if then we had taken a hundred of these little balls and thrown them, so that they all hit the ninepin at the same time, the effect on the pin would have been identical with that produced by the one big ball.

We can consider these little molecules, then, in a gas as moving with very great speed in all directions, and a very great number of them hit the surface of the mercury every second, so that they produce that resistance to pressure which Boyle described as "the spring of the air."

If we decrease the volume of a gas by increasing the pressure, more molecules will hit the mercury in the same time, and the resistance to pressure will be correspondingly increased. Now let us see whether we can get anything corresponding to this pressure in the case of our sugar solution.

Pressure of Dissolved Substances—i.e., Osmotic Pressure.

In order to do this we must get our sugar molecules somewhere where they can exert pressure without the water molecules with which they are mixed exerting pressure too. This is not a very easy thing to do; but, fortunately, it happens that there are a few membranes which will let the little water-molecules slip through them, while they stop the big molecules of sugar. So let us take a long tube and close it at the bottom with one of these membranes, and then, after filling it with our sugar solution, put the closed lower end in a basin of water. The sugar-molecules are now beating against that membrane at the bottom and producing pressure, so that water enters through the membrane, to balance the pressure, by raising the level of the solution in the tube until the solution in the tube stands very much higher than the water in the basin outside, showing that there is a great difference of pressure due to the pressure of the sugar molecules only. This pressure is called the "osmotic" pressure of the solution.

Since this osmotic pressure is due to the bombardment of the molecules of sugar, it is clear that it is the same thing as the pressure due to the bombardment of the molecules of a gas. And, indeed, measurement of the amount of the pressure shows that the osmotic pressure of a substance in solution is equal to the pressure which the substance would exert if it were confined in the same volume in the state of gas.

Osmotic Pressure and Molecular Weights.

According to the molecular theory of gases, we consider that equal volumes of all gases at the same temperature and pressure contain the same number of molecules (Avogadro's law), so that when we weigh a litre of oxygen, and find that it weighs sixteen times as much as a litre of hydrogen, we think that it does so, not because it contains sixteen times as many molecules, but because each molecule weighs sixteen times as much. And so for gases the weight of the molecules, or the "molecular weight," as it is termed, can be found from the weight of the gas which occupies a fixed volume at a fixed pressure. And in just the same way, since, for a dissolved substance, the volume of the solution corresponds to the volume of a gas, and the osmotic pressure to the pressure of a gas, so the molecular weight can be found from the weight of the substance which gives a fixed osmotic pressure in a fixed volume of water.

Molecular Weights from Physical Properties.

But, unfortunately, measurements of osmotic pressure are not easily made; the membrane used consists of a fine slimy precipitate of copper ferrocyanide, made by immersing a small porous pot in a solution of potassium ferrocyanide, and filling it inside with copper sulphate so that the two solutions meet in the inside of the walls of the pot and precipitate the copper ferrocyanide there; but this membrane is continually breaking under the very large pressures employed, and the method is extremely difficult to render accurate. Fortunately, however, it can be shown that the rise of boiling-point and lowering of freezing-point which take place when substances are dissolved in a solvent depend upon the osmotic pressure of the dissolved substance. For instance, pure distilled water freezes at 0 deg. C. Now, if we dissolve one gram of sugar in 100 cc. of water we shall find that this solution will freeze, not at 0 deg., but at .054 deg. below zero, and if we dissolve two grams in 100 cc. it will freeze at .108 deg. below zero, and so on.

And, again, we find that equal numbers of molecules, which produce equal pressures in gases, and equal osmotic pressures in solutions, produce equal lowering of the freezing-point or raising of the boiling-point. So that we can calculate the molecular weight of a dissolved substance from the weight necessary to produce a fixed lowering of freezing-point. The fixed lowering of freezing-point taken is the amount produced by the molecular weight in grams per litre, which has been called a mol.

The molecular weight of sugar $C_{12}H_{22}O_{11}$ is 342, and consequently if 342 grams of sugar are dissolved in a litre of water, we shall get our unit lowering of freezing-point, which experiment shows to be 18.5 deg. C.

But if we dissolve $23+35.5=58.5$ grams of sodium chloride in a litre of water we shall find that it does not produce 18.5 deg. depression, but a very much greater amount, showing that since equal numbers of molecules produce equal depressions, we must

have here many more molecules, and these molecules can only have come from the splitting up of our original molecules.

So that we see that some substances, among them nearly all salts, split up, when dissolved, into more molecules than they originally possessed.

And for the cause of this splitting up we must examine some electrical experiments, which we will next proceed to do.

C. E. KENNETH MEES, B.Sc., F.C.S.

PAPERS ON PRACTICAL PHOTOGRAPHIC OPTICS.

II.

The following methods of "Lens Calculations without Arithmetic" form the second of a series of chapters on photographic optics, the first of which, on "Focussing Scales and Depth of Field," appeared last week. Other articles will deal with "Disks of Confusion, and Distances beyond which all Objects are in Focus," and "The Speed of Telephoto Lenses when Employed on Near Objects." We have interspersed Mr. Lockett's text with the equations on which his geometrical constructions are based.

Focal and other calculations by the ordinary arithmetical methods are often intricate and involved, whereas the same problems geometrically considered are frequently very simple, and probably the few simple problems here given may prove of assistance to some workers. So far as the writer is aware, they have not previously been published. The first problem, although interesting, is simply given as a prelude to the very practical one which follows.

Problem I.—To Find the Greater and Lesser Conjugate Foci.

On any line set off a distance A B (Fig. 1), equal to the distance between the object and the focussing screen, or image. At A erect a perpendicular A C, equal to the size of the object. At B erect a perpendicular B D, equal to the size of the image. Join A D and B C, and where these lines intersect at E draw the line E F, parallel to D B, cutting A B in F. Then A F and F B are the greater and lesser conjugate foci respectively.

I. $FB : AF :: BD : AC$ (similar triangles).
 $u : v :: \text{image} : \text{object}.$

i.e., F B and A F are the conjugate focal lengths.

Problem II.—To Find the Principal or Equivalent Focus of a Lens.

Set up the camera and focus sharply with open aperture on any object of convenient size. Measure the distance between the object and focussing screen and obtain the conjugate foci as in the preceding problem. Now, on B D produced (Fig. 2) mark off B G equal to B F. Join G A, cutting E F produced in H. Then H F is the principal or equivalent focus of the lens. The beautiful simplicity of this formula, as compared with the ordinary arithmetical method, is worthy of notice. It will be seen that there is no need to ascertain the ratio between the sizes of object and image; nor is it even necessary to use a measure of any kind, since all the requisite information may be obtained with a piece of string and a pair of dividers, setting down the various distances direct, on a suitable sheet of paper, with the aid of a T or set square.

II. $HF : BG :: AF : FB.$
 $HF : u :: v : v + u.$
 $HF = \frac{uv}{v+u}$
 $\frac{1}{HF} = \frac{1}{u} + \frac{1}{v}$

i.e., H F is the focal length.

Problem III.—To Find the Conjugate Foci for a Given Size of Image, with a Lens of Given Focus.

This is another very practical problem, obviously available for enlarging, copying, and reducing, as well as to ascertain the necessary length for studios, etc. On any line set off A B (Fig. 3) equal to the size of object, and B C equal to the size of image required. At B erect a perpendicular B D equal to the focal length of the lens. At A erect a perpendicular A E, and at C another perpendicular C F. From A draw a line through D, cutting C F in H; and from G draw a line through D, cutting A E in G. Then A G and C H are the required

Fig. 1

Fig. 2.

conjugate foci; or A G and C H added together are equal to the necessary distance between object and image. It will no doubt be remarked by some that this diagram (Fig. 3) is exactly similar to one given by Mr. T. Bolas in "The British Journal Photographic Almanac" (1905, p. 710), for the totally different purpose of obtaining the combined focal length of two lenses in contact. The coincidence is extremely interesting, and embodies what is evidently a principle well worth further examination.

The next two problems are, perhaps, not so generally useful as the two last, but are notable for even greater directness and freedom from complication.

Problem III. is a variant of I.

Problem IV.—To Find the Focal Length of a Lens, the Greater Conjugate and Ratio of Image to Object being known.

Draw a line A B (Fig. 4) equal to the greater conjugate, and from B, at any convenient angle with A B, draw a line B C. From B, with any radius, step off a series of equal divisions, equal in number to the ratio *plus* one. In the example given, the ratio is supposed to be 4, so that five equal divisions are accordingly marked off. Join the last division and A; through the next division (in this case 4) draw the line 4 D parallel to 5 A. Then A D is the required focal length.

By similar triangles—D : D-F :: r+1 : r.

$$\text{i.e., } \frac{D-F}{D} = \frac{r}{r+1}$$

which is the same as $F = \frac{Dr}{r+1}$ the equation for focal length.

Problem V.—To Find the Lesser Conjugate, the Greater Conjugate being known.

Draw a line A B (Fig. 5) equal to the greater conjugate. At A erect a perpendicular A C, equal to the size of object. From C step off C D equal to the size of image. Join C B, and through D draw D E parallel to C B, cutting A B in E. Then E B is the required lesser conjugate.

$$EB : AE :: CD : AD$$

$$v : u-v :: \text{image} : \text{object-image.}$$

$$\frac{\text{Object}}{\text{Image}} = \frac{u}{v}$$

These are but a few of many remarkably concise and convincing problems in which geometry is capable of coming to the aid of the embarrassed photographer, removing the necessity of troublesome calculation with, perhaps, a host of refractory fractions. No doubt sufficient has been said to indicate the value of a deeper study in this direction. It is

not necessary, in practice, that the diagrams should be drawn to full size measurements. It will commonly be found more

FIG. 3.

FIG. 4.

FIG. 5.

convenient to use a scale of one-eighth to the inch, reading off eighths of an inch as inches in the result.

A. LOCKETT.

THE WEEK IN HISTORY.

The Old South London.

NEXT Wednesday, May 10, I shall be thinking of that day forty-six years ago, when the first and original South London Photographic Society came into being. The life and soul of its inception, as of its brightest activity, was my old friend A. H. Wall, unknown, perhaps even by name, to many readers of these lines, but still hale and hearty, and congenially employed in the pacific borough of Stratford-on-Avon. The South London made Walworth its centre, and showed the only other two societies in London at that time—the present Royal and the moribund North London—how to combine the character of a club with the technical activities of a photographic society. Its social management was a great feature. The members sat round a table, and did not rise formally to address the chair. It was a curious fact that the majority of the members lived north of the Thames, a fact which led at length to the removal of the meeting-place to the City of London College, Leadenhall Street, whence in 1873 the society soared westward to Arundel Hall, in the Strand, and again further west two years later to the Society of Arts, where it remained until its demise.

The South London was an energetic society, and in its earlier years had its experimental committee to investigate technical matters connected with photography. As showing the esteem in which its president, the Rev. F. F. Statham, was held, I may say that he was first elected on its formation, and he held the position up to the time of his death, which occurred in 1885. Although he went out of office each year, he was always unanimously re-elected—not once during the whole period was another

president even proposed. The society ceased to exist in 1887, when it handed over its minutes and archives to the Photographic Club, the existence of which body, by the way, was due to the members of the South London. It arose in this way: At the conclusion of the winter session in 1879, when many things of interest were coming to the front—gelatine photography being one of them—it was thought that something should be done during the vacation. Mr. Brittlebank, one of the members who then had a studio in the Tottenham Court Road, in the block of buildings now removed in widening that thoroughfare, kindly placed his rooms at the disposal of the members to meet in weekly, which was at once accepted. The meetings were known as the "Brittlebank meetings." At the end of the society's vacation, as these weekly meetings had proved so interesting and instructive, it was proposed to form a Photographic Club. A meeting was held at the Freemasons' Tavern on November 19, 1879, with the late Mr. Jabez Hughes in the chair, and the Photographic Club was formed.

Niepce's First Photograph.

Among the letters of Nicéphore Niepce to his brother is one written May 9, 1816—eighty-nine years ago on Tuesday next—in which he announces his first fixing of the camera image. He used the lens of a microscope, and found that he could record objects out of doors even when the sun was not actually shining. Niepce named his study "heliography" (drawing by sunlight), but from this time forth he might have used the term "photography."

HISTORIETS.

DIAPHRAGM NUMBERS.

Editorial Note.

[We have received the following, with a request to publish it, from Mr. F. M. Steadman, who writes from Prado, 94, Havana. In complying with the wish we desire to disclaim particularly any responsibility for the communication, and to announce beforehand our unwillingness, to explain, precisely what it is all about. Though we have read it more than once we should not feel qualified to speak positively. Apparently Mr. Steadman's system is based on some kind of circular measure, but until we have before us a more intelligible account of it than that which follows, we would prefer to say nothing about it, except that as it stands the system seems to have just about the same advantage as expressing plate speeds in miles per hour or focal lengths in terms of fiddlesticks.—Eds. B.J.P.]

In my new mathematical method of dealing with light, the "cone unit" is called the "cu." and has 1-64th the convergence of a hemisphere. If a light source be of uniform intensity throughout two cu's of it will create upon a surface impinged upon twice the intrinsic intensity of one "cu." This unit-cone is negligible close to $f/2.8$ (the square root of 8) in form, and for practical purposes may be said to have that form. To reduce any diaphragm or other unit-cone therefore to its "cu" value, it is only necessary to divide 8 by the square of the f value of that cone.

Thus, $\frac{8}{f/2.8^2} = \frac{8}{8} = 1$ cu or 1-64th hemisphere, and in like manner,

$$\frac{8}{f/4^2} = \frac{8}{16} = \frac{1}{2} \text{ cu}$$

$$\text{and } \frac{8}{f/4.5^2} = \frac{8}{20.25} = \frac{1}{2.53} \text{ cu}$$

The practicability of this method may be appreciated by the following simple problem. During the last full moon I desired to make a moonlight view of the roof below my window, and measured the moonlight as follows:—With a new lens, made by Bausch and Lomb, but not yet advertised, which works at $f/4.2$, or creates a light unit of that form at the full aperture, I focussed the moon against a piece of Eastman film, and obtained a visible impression of the image in 16 seconds. Then I formed the problem: If an $f/4$ (practically) cone of moonlight would do certain work in 16 seconds, how long would it require the natural cone of the moon to do that work?

Since the moon is about 100 times its own diameter from the earth its natural cone (as its rays impinge upon any one point on the earth) has an f value of 100.

$$\frac{8}{f/4^2} = \frac{1}{2} \text{ cu through lens}$$

$$\frac{8}{f/100^2} = \frac{1}{1250} \text{ cu, naturally.}$$

Now, by analysis, if half a "cu" of light will perform certain labour in 16 seconds, one "cu" would do it in eight seconds, and 1-1,250th of a "cu" would require 1,250 times 8 seconds, or practically 21 minutes. By reason of there being no absorption of glass in the case of the natural moon, this time was reduced to 16 minutes.

Now Eastman film tints 16 times as fast as "Solio," and the intensity of the moonlight therefore, by the "first appearance time" on "Solio" (which method was adopted officially by the P.A. of A. at St. Louis last October), would be 16 times 16 minutes, or 256 minutes.

Now by my method the actinic of the light (by the "first appearance" "Solio" method) is always the exposure with the speed diaphragm of the subject in hand.

The speed diaphragm of such a subject (classed as "average object in mid distance") is $f/32$, or U.S. 64, and with that diaphragm,

therefore, the full normal exposure would be 256 minutes. To use diaphragm $f/4$ (U.S. No. 1) then the following problem must be performed:—The speed diaphragm, $f/32$, or U.S. 64, is equal to 1-128th of a "cu" (in the case of the U.S. diaphragm half is divided by the number to obtain the "cu" value of the cone formed).

The cone desired to be used, $f/4$, or U.S. No. 1, is equal to half "cu." Then if 1-128th of a "cu" of light will give a normal exposure in 256 minutes one "cu" will perform the labour in 1-128th of 256 minutes, which is two minutes, and a half a "cu" will do it in twice two minutes, or four minutes.

The normal exposure therefore with $f/4$, or U.S. No. 1 was found to be four minutes, but as I desired to diminish the details in the shadows to obtain an effect more in harmony with moonlight in nature, a quarter normal exposure, or one minute, was given.

The film was developed normally by the time method, and afterwards intensified, as it was clear, would be required by reason of the quarter normal exposure. A print is sent to the Editors.*

Would it not be logical to take the numbers of a diaphragm the actual unit values of the cones they form, or 1 divided by that unit value? In that case $f/2.8$ and U.S. No. 1 would be 2, and it would be known to be half the convergence of No. 1, and diaphragm $f/8$ and U.S. No. 4 would be No. 8, and would be thought of as 1-8th of a "cu." or unit. All light-cones may be thought of in simple "cu." value (up to $f/1$ with negligible error), and if a window averages 3ft. in diameter, and a head is 6ft. away from it, the f value of

the light-cone at a point on the face is $f/2$, and $\frac{8}{f/2^2} = 2$ "cu's."

When the sun is 30 degrees from the horizon, one "cu." of sky creates an intensity about 32 seconds by the "first appearance" Solio method, and therefore two cu's." of sky would create an intensity of 16 seconds, which would be the exposure with the speed diaphragm of the subject in hand.

With this scale of diaphragms, which recognises the f value of cones as the basis of calculation, the numbers would stand for the actual working capacity of the cone which the diaphragm formed, and would allow the ordinary reasoning powers of the worker to apply in their use.

It is true that the numbers themselves are the same as the present U.S. scale—i.e., 1, 2, 4, 8, etc., but this scale has no logical physical reason to be, as the selection of $f/4$ to be U.S. No. 1 was but a matter of convenience decided upon by the R.S. Committee when the U.S. diaphragm scale was recommended.

The "cu." system, on the contrary, is based on the complete sphere as a natural physical constant. The sky as light source measures 64 "cu's." since it occupies a half sphere in relation to any point upon which its rays impinge.

The sun, whose natural cone (to the earth) is about $f/107$ measures $\frac{8}{107^2}$, or 1-1,460th of a "cu." The law which directly causes intensity is that of impingement, and not that of radiation, and the solid angle of an impinging cone therefore is the dimension which should be unified, and which the "cu." does unify in a popular manner. And since diaphragms govern impinging cones there is no need of their having a different scale from that which can be applied to any other cone as that of the sun, or moon, or a window. The "cu." method annihilates the truth of distance and area in dealing with light only, in the calculation of intrinsic intensity, which is the truth of light most important in photography.

F. M. STEADMAN.

* The print has not yet come to hand.—Eds. B.J.P.

PORTRAIT LIGHTING WITH THE COOPER HEWITT MERCURY-VAPOUR LAMP.

As recent articles in these pages have already stated, the mercury-vapour lamp has been edgaging the serious attention of professional photographers in the land of its commercial birth, the United States, although very little has yet found its way into print on the subject. Hence there is good reason why space should be found for the experience of Mr. Felix Raymer as communicated to "The Camera." Mr. Raymer has the reputation of being a practised technician in lighting, and it is therefore of interest to note his comparison of the new artificial illuminant with daylight.

My claim (says our author) has been (and is yet) that there is no difference in lights of any style, shape, or nature, so long as the operator knows how to use the light. It is not that one style light will produce a better effect than another style light, but it is that one operator will work his light in such a way that he will secure a better effect than another operator would. So I found it in the use of the Cooper Hewitt light. I had never tried to make a negative under one of them before, so can truthfully say I knew nothing of them any more than I would know of any other source of light, but the proposition was for me to work that light, and get as good work from it as I could get from daylight. Therefore, when I was asked to give a demonstration of the light before a recent convention, I recalled all I had said both to the conventions in previous years, and also through the magazines, and at once proceeded to apply my own directions as given to others for working a strange light, and I was not disappointed in the result.

The Mercury Lamp as a Sky-light.

In working the Cooper Hewitt light, it is necessary to do so as though it were nothing more than a small sky-light, and in fact it resembles one very much in its construction, the main difference being that it is so small in size that one would naturally think it would require longer exposure than our "old-time" sky-light, which had covered many square feet of light space. This is just where we all make a mistake in working it for the first time. As a matter of fact, it requires *as little or less exposure than any sky-light* I ever stood under. There is something remarkable about the actinic value of the light. One particular feature I noticed in its use, and that is, in place of the peculiar tone given to the face under it, confusing the operator, it makes his judgment of tone value much better, and he is in a position to secure more what he actually sees under the light than ever before. The high-lights are brought up strong and clear cut, while the middle tints and lower tones fall into place as no daylight will show.

How to Light a Portrait.

For a portrait effect the subject should be posed at a point where all of the light will fall on the face from the front. I mean by

this that there should be no back light coming from the side or rear. To get this result it will be necessary that the subject be posed about 2 ft. back from one side of the light. The direction for the light falling on the face should be from an angle of about 45 deg. In this way there will be no more of side light than top light, but an even distribution of both. To get this direction, the subject should be seated about 6 ft. out into the room from the light (this is supposing the ceiling of the room to be about 12 ft. high, and the light fitted into it for that height ceiling). After trying the light with the subject seated at this distance, it can easily be seen whether the light is falling right or otherwise. Have the subject turn his face away from the light until he is facing directly away from it, and then begin to turn slowly toward the light until the point is reached where the ear on the shadow side of the face is about to come into light, and then stop. Do not allow the ear to come into the light, but go as far in that direction as possible without doing so. When this point is reached, look at the shadow that falls from the nose towards the shadow cheek. If it runs across the cheek it is an indication that the light falls too low on the subject. To correct it, all that is necessary will be to move the subject nearer to the light. This will cause the light to take a more downward course, and which will, of course, throw the shadows in the same direction.

If the shadow from the nose falls directly under it, it is an indication that the light is falling on the subject from too high a source. The plan of correction would be to move the subject farther from the light. This will throw the shadows further across the face.

But if the shadow takes a course running toward the corner of the mouth, it will be all right, as that is near enough to the angle of 45 deg. for all practical purposes.

Maxims in Mercury-vapour Lighting.

I will give a few suggestions for using the light that may be of service to many.

First.—Notice the little sparks of light that appear in the eyes. If the one in the shadow eye is not shown or is too faint, it will indicate one of three things: (1) The face is not turned far enough to the light; (2) the head is too low; (3) there is too much top light being used—move the subject further from the light if this is the cause.

Second.—Notice the highest light on the face. If it is in the centre of the forehead, the face is too far to the light. If it is on the temple, the face is too far from the light. The proper place for it is directly over the *light* eye.

Third.—Be careful as to exposure. The light is a faster light than any operator will think on his first trial.

OXYGEN Cylinder Explosion.—A shocking explosion took place at Winterthur (Zurich) on Saturday last, in the physics section of the Cantonal Technical School, as the attendant was unpacking the oxygen cylinders for a lecture with lantern slides. The man's body was blown to pieces, parts of it being hurled to a great distance, while a number of pupils in a neighbouring class-room were seriously injured. Had the explosion occurred a quarter or an hour later there must have been terrible loss of life. The explosion was heard all over the town. The instruments in the laboratory, to the value of some £400-£600, were entirely destroyed. Explosions of this kind are fortunately of rare occurrence, the last that occasioned loss of life in England happening some years ago in the Fenchurch Street

Railway Station, when a youth who was carrying a cylinder of oxygen was the victim. The preparation and testing of gas bottles has, however, been brought to such a reliable state in this country that users need have no fears as to their employment under any reasonable conditions.

THE committee of the Carnegie Public Library, Coatbridge, have decided to inaugurate the opening of the building with a photographic exhibition. The date will be May 18, and six open classes are announced. Silver and bronze plaques will be at the disposal of the judges in each class. Entries close May 12, and full particulars will be sent on application to the hon. secretary, G. W. Campbell, Ailsa Cottage, Coatbridge, N.B.

CLOUD NEGATIVES.

CLOUD Negatives and Printing was the subject of a lecture by Mr. H. W. Bennett, on April 11, to the members of the Birmingham Photographic Society. At the outset it was pointed out that this was a branch of photography very much neglected by most amateurs. There were supposed to be so many difficulties to encounter that most fought shy of cloud printing, and selected subjects which needed none. And the existing text books did not cast much light on the matter, so that one was left to learn by personal experience how to insert clouds into prints, and how to secure good cloud negatives.

The Necessity for Clouds.

The necessity for improving pictures by filling in the sky portion with suitable clouds was apparent to everyone with an artistic eye. The sky in nature can never be represented by white paper, and "bald headed" photographs could lay no claim to being pictures. If clouds were not printed in, at least tone down to a greyish tint, which would much better represent sky tones than white. The occasions on which one can obtain clouds and landscape on the same plate are few and far between. When possible, of course, do so, and save much time. The difference in exposure required for sky and landscape, however, precludes much hope of success.

Points to be Considered.

Having decided to study cloud printing, let us examine what principles we have to work upon. In the first place the rules of composition apply as much to clouds as to landscapes. These are briefly: (1) There must be agreement between the two parts of the pictures; but how often is this rule neglected?—clouds are wedded to landscapes which they do not suit, with the result that the eye is at once drawn to the sky, and an irritating effect is produced. The lighting of the clouds must be from the same direction as the landscape, and their tone values should be the same. Remember that in the sky the deepest shadow will always be lighter than the deepest part of the landscape, and allow for this. (2) The form of clouds must be studied. Note carefully the nearer the horizon the lighter the clouds; often they become little more than streaks. (3) There should be a principal point of interest in the cloud as in the landscape portion, and the same form should never be repeated in the same picture. (4) The

direction of wind will make a difference in cloud-shapes, this fact should be noted and used as experience directs.

Practical Hints.

The actual photographing of clouds was next considered. The best months in which to secure cloud negatives were April, May, and September, because then the forms were continually varying, and the light was not so strong. Windy weather was the best. Choose a good open space and include some landscape on each plate. Keep the camera horizontal and raise the front, this would enable the camera to be swung round while the view still remained vertical. Focus on some marked points in the landscape, then get ready for the exposure, and study the clouds until a suitable combination appears, when the exposure should be made. A lens should be used of shorter focus than that used for the landscape, with a view to getting the size of the clouds to harmonise better with the picture.

Isochromatic plates were essential for very light clouds; for heavy ones the ordinary did equally well. A screen which increased the exposure about five times should be used, but not a deep one or the colours would be over corrected. The exposure must be very short, and the negative kept thin, to ensure quicker printing. Backing of plates is essential to avoid the spreading of light, the risk of which is great in cloud photography.

Methods of Printing.

The landscape portion must be printed first, then masked and the clouds inserted. A large printing frame should be used, and the mask fastened on the outside, with the edges slightly projecting; the light would then spread underneath, and there would be no harsh line. For platinotype, a mark must be made on the paper after the landscape part is printed, then mask as before. For carbon, put a mark in some white colour on each end of the negative, then press the tissue down, thus obtaining a mark which would be a guide where to apply the mask.

In conclusion, one thing is essential if our pictures are to be successful; nature must be studied, and many negatives obtained from which a selection could be made. It is useless to attempt to obtain one universally useful cloud negative. Nature is ever varying, and one value of cloud photography is to enforce this lesson.

SATURN'S Satellites.—Professor E. Pickering, of Harvard University, has discovered a tenth satellite of Saturn by means of the Druce photographic telescope. The period of the satellite is twenty-one days. It is stated that the character of motion is direct. The period is very nearly equal to that of Hyperion, the faint satellite discovered by Mr. Lassell, of Liverpool, in 1848. The brilliancy of the new object is only about one-sixteenth of that of the older satellite, or three whole magnitudes fainter, and could only possibly have been discovered by photographic means.

THE Röntgen Congress, to celebrate the tenth anniversary of the discovery of the Röntgen Rays, was opened in Berlin on Sunday in the presence of a number of high officials, university authorities, professors, and many German and foreign scientists. The objects of the Congress are twofold. In the first place it will provide an opportunity to survey the brilliant achievements of the past decade that have been rendered possible by Professor Röntgen's discovery, and, in the second place, again to do public honour to the discoverer himself.

PHOTOGRAPHIC Evidence.—In a series of betting prosecutions at Grimsby on Friday last, the police brought a snapshot taken by a policeman in concealment as evidence. The photograph showed one of the defendants receiving money from a man in the street.

Our bright contemporary *The Globe* states that "there is to be published in New York an album of portraits of the principal members of Parliament of each country," and adds, "six hundred and seventy members of the British House of Commons are said to have forwarded their photos."

EXHIBITION OF ALPINE PHOTOGRAPHS.—Another exhibition of photographs by members of the Alpine Club and others will be on view at the club rooms, 23, Savile Row, W., from May 10 to May 31. Previous exhibitions by this club have produced many fine mountain pictures of great beauty and interest, and the forthcoming show should be no exception.

THE syllabus of lectures, outings, etc., of the South London Photographic Society has been sent us. The evening meetings at Collyer Hall, High Street, Peckham, are continued during the summer in addition to a comprehensive list of excursions. Saturday half-day cycle rides are also provided for, and should prove popular, and various competitions are likewise announced. The date of the Seventeenth Annual Exhibition is fixed for March 3 to 10, 1906. Full particulars as to membership, etc., will be forwarded by the Hon. Secretary, H. Creighton Beckett, 44, Edith Road, Peckham, S.E.

Photo-Mechanical Notes.

Journalistic Changes.

HERR OTTO MENTE, who was formerly with Klimsch and Co., has joined the Photo-chemical Laboratory of the Technical High School, Charlottenburg, Berlin, and has also assumed the joint editorship of the "Zeitschrift für Reproduktionstechnik," vice Dr. Aarland resigned.

The Use of Screens in Copying.

In the "Zeitschrift für Reproduktionstechnik" attention is directed to the use of coloured screens for copying ordinary photographs, such as carbon and gum bichromate prints, many of which are now met with on coloured supports. A cell with liquid filters is suggested as the handiest, and practically only three solutions are required—namely, a solution of tartrazine, a mixture of tartrazine and brilliant acid green, and a solution of eosine. The tartrazine should be used with a blue pigment image on a white or yellow paper, and even with black or brown images on yellow paper it gives better contrasts. The green filter is useful if red or reddish-brown images on yellowish paper have to be reproduced, and it is useful for prints toned with uranium. The red filter is not much in request, and is most useful when bright blue images are met with. Practically these are the so-called "contrast filters," which by absorbing more or less of the colour reflected by the images, produce a black; if the existing contrasts in a coloured print are too great they can always be lessened by using a filter of the colour of the image.

Rough Paper Prints.

The copying of prints on rough-surfaced papers very frequently presents considerable difficulty, and the resulting negatives are too often but photographs of the surface irregularities with a minor image of the actual print. To overcome this difficulty, says the above-mentioned paper, such prints should be copied out-of-doors on a dull day, as really satisfactory results cannot be obtained with the electric light. The use of "contrast" filters will also be found advantageous with such subjects.

Rules for the Half-tone Screen.

THE following are some of the instructions given to screen-negative students at the London County Council School of Photo-Engraving, Bolt Court, Fleet Street, E.C. :—

To clean the screen, use the China silk and not the duster.

Be careful the screen is thoroughly secure in the camera.

To reproduce an average copy the same size :—

The distance of the screen with a lens of 18in. focal length, using wet collodion, will be approximately :—

For the 100-line screen, 8 millimetres away from the plate.	
" 125-line " 6 " " "	
" 133-line " 5 " " "	
" 150-line " $3\frac{1}{2}$ " " "	
" 175-line " $2\frac{1}{2}$ " " "	

These distances are for screens in which the black lines and white spaces are equal, and are measured from the surface of the screen.

Stops to be used will be of a diameter of, say, 1-90th of the camera extension (stop marked $f/45$) for exposure for the shadows, supplemented by an exposure for the high lights, with a stop of a diameter of, say, 1-30th of the camera extension (stop marked $f/16$) for 1-20th part of the time given to the shadow exposure.

When using dry plates or collodion emulsion for making negatives it will probably be found necessary to have the screen nearer than above.

With greater reduction, the stops may be smaller in size, and the screen distance may be less.

With greater enlargement the stops may be larger and the screen placed farther away.

With a lens of shorter focal length, the stops may need to be smaller or the screen distance less.

With a lens of longer focal length, the stops may need to be larger or the screen placed farther away.

Originals, having very heavy contrasts, may need smaller stops, or closer screen distance, or both.

Originals, with very flat contrasts, may need larger stops, or longer screen distance, or both.

When using suitable transparencies as originals the screen distance may be 25 per cent. more than above.

"Flashing"—i.e., exposing with white paper over the original and a very small stop in the lens should only be resorted to when the shadows of the original are very dense, and should, as a rule, not exceed 1-20th of the total exposure. Round stops should generally be used in preference to square; only under exceptional circumstances may square stops with corners extended be used.

Before exposing, make quite certain your arc lights evenly illuminate the copy, that the mirror, or prism, is perfectly clean, and that the image is central on the ground glass.

Lectures on Three-Colour and Orthochromatic Work.

Last evening, May 4, at eight o'clock, commenced a series of nine lecture-demonstrations on the principles and practice of orthochromatics at the L.C.C. School of Photo-engraving, Bolt Court, Fleet Street, London, E.C. The lecturer, Mr. A. J. Bull, is known to many of our readers as very thoroughly qualified to speak on the subject, and the course of lectures ought to be well attended. The fees are 2s. 6d. for the course, or 1s. for a single lecture, and we believe the series is open to persons directly or indirectly connected with the illustrative crafts. The syllabus is as follows:—Nature of light and colour; selective absorption and other causes of colour effects; the spectrum; nature of ordinary colours; primary colours. Properties of orthochromatic plates and methods of testing; safe lights for the dark-room; use of light filters; orthochromatic photography. Three-colour photography by the additive method. Three-colour photography by the subtractive method; nature of best reproduction colours and negative records; adjustment of colour filters to plates; effects of incorrect filters and plates; position of the filter. Three-colour negative making; details of the indirect method; avoidance of screen pattern; a direct method by the use of collodion-emulsion and the dry plate; fine etching; proving. Four-colour processes.

THE prize competition promoted by Messrs. Burroughs Wellcome and Co. will close on May 15. Prizes of five, three, and two guineas respectively are offered for negatives developed with "Tabloid" Pyro-Metol Developer. Entry forms and full particulars may be obtained from all chemists and dealers, or from Messrs. Burroughs-Wellcome and Co., London, E.C.

SHORTNESS of memory is a public as well as an individual failing, and many who learn of the death of Mr. W. H. Alexander in his 73rd year will need to be reminded that it was he who, with such splendid generosity, provided nearly the whole of the money for building the National Portrait Gallery. Forty-five years ago the nation's collection of portraits was housed under temporary conditions in Great George Street, and although they later found a more fitting home at South Kensington, the risks of fire made apparent by the subsequent outbreak at the Indian Museum led to their being carried away to the museum in Bethnal Green. Then it was that Mr. Alexander made his princely offer of £80,000, and the Treasury adding £16,000, the fine building, near neighbour to the National Gallery, was erected and opened nine years ago.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

The following applications for Patents were made between April 17 and 22:—

CAMPHOR.—No. 8,297. "Improvements in the manufacture of camphor." Chemische Fabrik auf Actien (vorm E. Schering), 24, Southampton Buildings, Chancery Lane, London.

CINEMATOGRAPHY.—No. 8,341. "A process of producing light projections by means of the cinematograph." Paul Effing, 41, Rominsenerstrasse, Berlin.

FINDER.—No. 8,453. "A portable finder to be fitted on the outside of the ordinary hand camera, showing the objects to be photographed the same size and in the same position as they will appear on the sensitive plate." William Henry Hawling, 1, Clarence Gardens, London Road, Bath.

NEGATIVE MAKING.—No. 8,458. "Production of photographic negatives by mechanical means." Edward Walter Kempton and Edwin Gordon-Bertram, 26, Speldhurst Road, Bedford Park, London.

PRINTS.—No. 8,616. "Improvements in process of copying, developing, fixing, washing, and drying webs of photographic paper and in apparatus for carrying the same into effect." Friedrich Heinrich Lange, 79, Augsburgstrasse, Berlin, W.

COMPLETE SPECIFICATIONS ACCEPTED.

Specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

CINEMATOPHGRAPHS.—No. 11,821, 1904. "Improvements in and connected with cinematographs and like apparatus." The improvements claimed are a special feeding arrangement, whereby the period of movement of the film is small in comparison with the period of rest and the clamping of the film whilst stationary, thus doing away with the flickering defect, and an improved effect is obtained by revolving a four-armed shutter. Arrangements are also made for adjusting the picture centrally in the mat whilst running. Fireproof tubes surround the optical axis, so as to prevent ignition of the roll of film and preventing the latter falling across the axis if accidentally broken. The feeding drum is arranged so as to grip the film only for a part of its periphery, and a special clamping device for periodically holding the film stationary, consisting of a loose mat and spring-controlled hinged frame. Joseph Mason, 25, Windmill Street, Shaftesbury Avenue, W.

DEVELOPERS.—No. 23,729, 1904. "Improvements in and relating to photographic developers." The applicants have found that the condensation products of paramidophenol, or its sulphite compounds, obtained by the action of aldehydes of the aliphatic and aromatic series, are superior to paramidophenol. The products obtained with formaldehyde and acetaldehyde are particularly suitable. The production of these compounds may be illustrated by the following example:—144.5 grammes of paramidophenol hydrochloride and 120 grammes of potassium bisulphite are dissolved in 440 ccs. of water, and, after cooling, 100 grammes of a 40 per cent. solution of formaldehyde are added. The sulphite combination of the product can be crystallised from this solution. As a developer, it is used in a dilution of 1 to 4 with a solution of 5 grammes of the sulphite combination, 25 grammes of potass. carbonate, and 25 grammes of sulphite of soda in 100 grammes of water.

New Apparatus, &c.

The Kodak Tank Developer. Made by Kodak, Limited, 57-61, Clerkenwell Road, London, E.C.

The merits of stand development for negatives on glass plates has long been recognised, and various tanks for the purpose have been devised from time to time. The application of the method to spools of films has now been accomplished by the Kodak Company, who, well to the fore, as usual, in all matters connected with economy of time, space, or labour in film photography, have evolved an ingenious piece of apparatus that bids fair to rival their well-known developing machine. The employment of the latter involves a certain

Winding the film on to the reel.

amount of manual labour, inasmuch the film during development has to be continually on the move.

In the new pattern developer, the process is practically automatic. The handle-turning operation during development is obviated, and the entire film is developed in a vertical position while stationary. The advocates for time development have substantially proved the advantages of what may be termed "development in the dark," and its application to the production of a batch of well-developed negatives from various exposures on a length of film has been well exemplified in the Kodak developing machine and the present form of developing tank.

Placing the reel and film into the developing tank.

The apparatus consists of a flanged reel, upon which is wound a long red celluloid strip or apron. A wooden box is supplied in which the film and black backing is wound from the camera spool on to this reel, and is protected from light by the red celluloid. So far, the operation is somewhat similar to that which takes place in the developing machine. After the film has been transferred from the spool to the reel, it is removed from the winding box, and can be handled with perfect safety in the light of an ordinary room.

The flanged reel is now removed entire (containing the apron, the black paper, and the film) and is inserted in the developing tank, as shown in the illustration. This tank is not unlike a jam pot in shape, but is highly finished and electro-plated.

Previous to inserting the reel, the tank is three-parts filled with developer. The reel is gently lowered into the solution, which quickly finds its way to all parts of the film, as the edges of the red celluloid

apron are separated by strips of serrated rubber, and development proceeds slowly and evenly. At the expiration of every two or three minutes it is recommended to withdraw the reel and replace it again upside down. With the developer recommended and supplied by the Kodak Company, development will be complete in twenty minutes. There appears to be little danger of fogging or sticking with this method, and batches of well-developed negatives should result.

When development is complete, the developer is poured off and the tank filled and emptied two or three times with clean water. The film can then be unwound, separated from the black paper, and cut into lengths for fixing in the ordinary way. These operations can be conducted in the light of an ordinary room, and no harm will come to the negatives.

Washing and drying are carried out in the ordinary way, and the film user who has not yet experimented with this form of development will be both astonished and pleased at the uniformity of the results obtained. The entire apparatus is produced with that finish and regard for details for which the Kodak Company are famous, and as it fulfils all that is claimed for it, the new developing tank should have a ready sale. The complete outfit is at present supplied in three sizes—the Brownie tank for No. 1 and No. 2 Brownie spools, the 3½-inch tank for all spools up to that size, and the 5-inch tank for spools not exceeding 5 inches, the prices being 10s., 20s., and 25s. respectively.

THE useful little list of the principal makes of plates and papers, etc., issued by Jonathan Fallowfield, 146, Charing Cross Road, W., to which we referred last week has now been sent to us in a neatly-bound form. As it is likely to prove a pamphlet of reference that will receive much use, the new form of issue is a good one. Every photographer should get a copy. This firm also announces a new automatic ferrotype camera called the "Taquina," for the rapid production of small circular photographs for brooches, etc. A full notice of this ingenious piece of apparatus will appear later.

New Materials.

Collodion Emulsion. Made by Mr. F. G. Willatt, 15½, Gordon Road, High Wycombe.

We have received from Mr. Willatt a sample of collodion emulsion which, he states, is made from methylated spirit, and can therefore be sold at 2s. 9d. for five ounces, 10s. pint, or even less in larger quantities. The treatment of the emulsion used wet is the same as usual; if required to be used dry, a simple preservative (as, for example, tea) is flowed over; the plate is then rinsed and allowed to dry. The emulsion works cleanly, giving good gradation, and is about the same speed as, or perhaps a little quicker than, another make against which we tried it. On drying there is a slight milkiness in the film, which, however, disappears on varnishing.

This emulsion, therefore, is quite suitable for lantern-slide making or slow copying work, but collodion emulsion now is most extensively used in three-colour work, and here this sample of Mr. Willatt's emulsion breaks down, as it is not susceptible to the addition of the most frequently used sensitising dyes. This is not due to the methylated spirit in the emulsion, as we have added methylated spirit to other emulsions without any ill effect as regards their sensitiveness, but it is probably due to the free nitric acid in the sample submitted. If Mr. Willatt can make an equally good emulsion without free acid, we should think his product would answer all requirements, and prove a formidable competitor to the more expensive German emulsions generally purchased at present.

Since the above was written Mr. Willatt has informed us that at present he is offering the emulsion only for copying and lantern

slides, but anticipates that he will be able to prepare an emulsion with methylated spirit suitable for colour sensitising.

The "H. H." developer. Sold by J. Rawlins, 3, Cross Lane, St. Mary-at-Hill, E.C.

Mr. Horsley Hinton's name used in connection with various photographic accessories has become such a guarantee of excellence that we were not surprised to receive samples of a new developer, entitled "The H. H. Developer," and we find on trial that it is really a very good developer indeed. If it is regularly used by Mr. Hinton, perhaps the secret of his successful negatives is thereby laid bare. The developer appears to be a concentrated form of our old friend pyro-ammonia, and as supplied by Messrs. Rawlins, will be found very handy to use and fairly quick in action. It gives negatives of a good printing colour, and does not clog up the plate with the pronounced yellow stain peculiar to some pyro-ammonia formulæ. Full printed instructions accompany the preparation, which will not be found expensive, as 1s. will purchase sufficient to make half a gallon.

The "Salon" Plate. Manufactured by the Gem Dry Plate Co., Ltd., Willesden Green, London, N.W.

The tendency towards high speeds for modern dry plates appears to have no limits. Manufacturers vie with each other in their endeavours to place before the photographic public plates which in addition to possessing the acme of speed retain all those good qualities that make for excellence and uniformity in negative production. Latitude, a quality that appeared until quite recently peculiar to plates of comparative slowness, is now apparently obtained with the greatest ease in the most rapid emulsions, and the new "Salon" plate just introduced by the Gem Dry Plate Company embodies these two qualities with distinct success. Of its great rapidity there can be no question whatever. We have experimented with samples submitted to us, and exposures of 1-120th of a second with stop $f/8$ made on a dully lit street scene at three o'clock on an April afternoon have given us well-exposed negatives showing full shadow detail.

We regard this as a somewhat severe test, and are quite satisfied that the high speed claimed for the "Salon" plate is fully substantiated. As a plate for the studio it should be extremely useful on dull days, particularly as there is no inclination to hardness in the image, even with the brief exposures we have given. On the contrary, a soft, quick-printing negative appears to be the usual result, but we found that forcing the development to any extent was apt to produce a slight veiling, which, however, could be disregarded as not affecting the printing quality of the negative. This veiling, or fog, was particularly noticeable when developing the first one or two negatives with metol-hydroquinone; but with the pyro-soda, or pyro-ammonia recommended by the makers, this can be regarded as no detriment.

With a pyro developer very high quality negatives indeed are produced, and even with the brief exposures referred to above excellent gradation and good printing quality result.

The increasing number of those who place confidence in laboratory measurements of a plate may be interested in studying the following measurements of the "Salon" plate made for us by Mr. C. E. Ken neth Mees, B.Sc.:

Speed number, Watkins, ferrous oxalate ...	288
Speed number, Watkins, pyro-metol ...	324
γ (density giving power of the plate) ...	2.21
K (velocity constant of development with standard ferrous oxalate developer)086
$T\gamma$ (time necessary to obtain the standard gradation of 1) ...	7 minutes

These results were obtained with plates from batch No. 4,167.

The Gem Dry Plate Company, Ltd., inform us that measurements by Mr. Watkins have given a Watkins No. of over 400, that is, in excess of the figure claimed by the makers. This is not the place to dilate on plate speed controversies. It is clear, we hope, that the "Salon" plate possesses extreme sensitiveness, and to this we would add the important statement that it is sold at the popular prices of 2s. 3d. per dozen half-plates.

Dr. Smith's new three-colour plates, the introduction of which we have already chronicled, consist of three films of emulsion, coated one on top of the other, separated by a film of collodion, which permits of the separation of negatives. The top film is sensitive to blue-violet, and gives the negative for the yellow or minus-blue print; the middle film is sensitised for orange and red, and gives the negative for the blue or minus-red print; whilst the lowest film is sensitised for yellow and green, and gives the negative for the red or minus-green print. The films are not only orthochromatised, but also stained to reduce the preponderating blue-violet sensitiveness.

The sensitiveness of the plate is stated to be 8 on Dr. Smith's scale, or $5\frac{1}{2}$ Scheiner, or $17\frac{1}{2}$ Warnerke, or 20 H. and D., or $f/32$ Wynne, and are fast enough to permit of exposures of about 1-10th of a second with $f/7$ in summer; smaller apertures than $f/16$ are not recommended. No light filters or screens are required.

After exposure the film must be cut through all round; the plate is then laid in a black envelope, and one corner of the same slit up; then a candle is lit, and, care being taken that the light does not fall directly on the exposed corner, the top film is cut through, and in the dark, or with very dim light, the film is transferred by means of a sheet of special paper to a sheet of gelatinised glass, and the temporary paper support is then stripped off. Precisely the same operation is performed with the middle film, and then the three plates are developed simultaneously, the separating collodion films having been previously dissolved by soaking them in methylated alcohol. Positives are prepared from the negatives thus obtained by one of the usual methods.

A REPORT of the new "Red Seal" plates of Messrs. Elliott and Sons, Ltd., Barnet, Herts, is held over till next week for want of space.

Exhibitions.

WATFORD PHOTOGRAPHIC SOCIETY.

The second annual exhibition of this Society was opened in the Watford Public Library on April 28. The awards made by the judge, T. Percivale Padwick, are as follows:—

First prize: "A. Lowestoft Fishing Smack," Miss M. J. Smith. Second prize: "Eventide," P. W. Morris. Third prize: "Card Houses," Mrs. L. Reid. Highly commended: "L'Amour," Miss Kate Smith; and "The Wane of Day," L. W. Shubbrook.

The Members' Classes were well supported, and the loan collection of pictures selected from the 1904 competition, Affiliation of Photographic Societies, formed a feature of the show.

BARRHEAD.

The second annual exhibition of the Barrhead Amateur Art Club (incorporated with the Scottish Photographic Federation) was opened by Bailie Paton on April 26 at the Public Hall, Barrhead, and has proved a great success. Over £30 worth of pictures and photographs have been sold, which speaks well for the quality of the exhibits. The judges were: J. W. Eadie, vice-president of the

Scottish Photographic Federation, and Dr. Richmond, and the awards were as follows:—Class 1, any subject: Silver Medals, A. W. Hill and Fred Judge; Bronze Medals, Wm. Clayden and J. A. Taylor. Class 2, open to Associates of Scottish Photographic Federation: Silver Medal, A. W. Hill; Bronze Medals, R. Wallace and R. Murray. In the Members' Classes, Medals are awarded to R. Murray, Dr. Corbett, Douglas Shanks, and J. M'Grouther; and Certificates to Dr. Corbett, J. M'Grouther, Douglas Shanks, J. Wham, T. E. Dickson, and R. Murray.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

May.	Name of Society.	Subject.
5.....	Wimbledon and Dis. Cam. Club	Members' Evening.
9.....	Royal Photographic Society ...	Three-Colour Photography with Examples. Mr. E. P. Butler.
10.....	Cricklewood Photo. Society	Flashlight. Demonstrated. Mr. Wilfred Emery.
10.....	North Middlesex Photo. Soc. ..	Various Tones on Papers by Development. Mr. Ernest J. Smith.
11.....	Richmond Camera Club	Annual General Meeting.
11.....	London and Prov. Photo. Assn.	Combination Printing. Mr. E. Humau.
11.....	Rugby Photographic Society ...	Annual General Meeting.

ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held May 2. Mr. J. C. Warburg in the chair. A practical demonstration on "Retouching," by Mr. Redmond Barrett, was the subject announced for the evening, but Mr. Barrett dispensed with the practical part of the demonstration, and treated the audience to a discursive series of statements regarding the process of negative improvement by means of the pencil. The lecturer ruminated on the position retouching has assumed in modern professional photography, and deplored its abuses, inasmuch practically all modern retouching was the same in effect, and that effect was bad and artificial. The tendency was to retouch all character out of a face by putting on too much work, and so making all portraits more or less expressionless and alike. His principles were:—To treat each negative as an individual study; to put on the minimum amount of lead pencil work consistent with the effect aimed at, and to allow the brain, not the fingers, to direct the pencil. By this means only was it possible to improve the negative and retain the likeness. A vigorous head and face should receive entirely different treatment from one lacking in force or character. In the one case the character of the sitter should be studied and assisted as much as possible by the retouching; in the other no work beyond the removal of blemishes should be attempted. Each touch with the pencil on the shadow side of a face had twice the effect of a similar touch on the light side, or dense part of the negative. Mr. Barrett stated there were no rules governing retouching. Simply make up your mind what was required in the way of improvement on the negative, and then do it. The delightful practicability of this axiom duly impressed the audience. Another self-evident truth expounded by the lecturer was that if a certain effect could be obtained with a small amount of work, say fifty touches with the pencil, it was quite unnecessary to employ 500 touches.

A series of questions put to the demonstrator elicited the following points:—The retouching medium should be applied with a small pad of gritless wadding, and should be rubbed with a circular motion over the parts to be retouched in widening circles until the medium was dry. By this circular motion it was possible to avoid varnish marking likely to occur, especially with negatives that had

been intensified. A medium pointed pencil was probably the best for all-round work, and the only advantages an expensive pencil had over the cheap article were that the point lasted longer and was free from grittiness, otherwise any form of hard pencil was suitable. A too fine point was quite unsuitable for large heads; as the space to be retouched could not be properly covered without a great deal of unnecessary work. For small work a fine point was useful, but not absolutely necessary. It was not necessary to frequently sharpen the pencil, as once the proper touch had been acquired turning the pencil during the progress of the work was sufficient to keep a good working point. In working on large heads a loose rubbing touch should be used, and no more pressure should be given than would be necessary to make a mark on the pile of white velvet; if too much pressure is employed either the pencil point will break and possibly damage the negative, or the surface will get slippery and refuse to take more lead. In this case, if it is necessary to add more density, the best plan was to apply a little moist colour with a fine-pointed sable brush. In any case it was not the pencil that did the work but the man, and therefore it could not be too strongly impressed on the retoucher to think before working, and to make up his mind just what is to be done. The object of retouching is to increase brilliancy and make a portrait. By forcing a high-light, the gain was not so much an increase of brilliancy in that light as the increase of brilliancy in the neighbouring shadows by contrast. A blurred negative or a negative of a sitter who had moved during exposure could be saved by placing definite high-lights in their proper places. The high-light, in any case, should always receive first attention when starting to retouch a portrait, otherwise if much work is done on the half-tones the lights will be lost, and it is often difficult to replace them in exactly the right position later. The lights on bridge of nose, forehead, and cheek bones should be secured before anything else is attempted, and the natural high-lights should not be confounded with the reflected lights arising from moisture on the skin during warm weather. It should be borne in mind that every touch of the pencil prints white, therefore too much retouching would flatten out all expression. It is better to soften severe expression than to take it away entirely, and in the case of a very open smile the lines of the face formed by the smile should be carefully retained, or a portrait merely showing the teeth would result.

Working on the glass side of the negative to lighten broad masses of shadow could be accomplished with water-colour or conté crayon, and if the retouching knife is used it should be employed on the plain film previous to varnishing. Always overdo the cutting process, as what is taken away can usually be put back by the pencil with better effect. The knife blade should be kept very sharp, and it will be found that the age of the negative has an effect on the ease of working. Mr. Barrett, in conclusion, reiterated his advice to think before applying pencil to negative, and impressed on his hearers the futility of doing too much work on a portrait when only a few touches were necessary. A hearty vote of thanks was accorded the lecturer at a late hour by the depleted audience.

The Secretary announced that on June 6 Miss Acland would give a display of her three-colour lantern slides of scenes at Gibraltar.

PHOTOGRAPHIC EXHIBITION AT KEIGHLEY.—During last week a photographic exhibition was held in the upper room of the Carnegie Library, at Keighley. The exhibitors, 55 in number, were represented by about 170 works, which Mr. T. C. Butterfield (Art master) and Mr. Alexander Keighley, F.R.P.S., have had the task of arranging. The members of the Keighley and District Photo. Association are, of course, the chief exhibitors, but there are also specimens from Birmingham, Leeds, Sheffield, Hull, and other parts of the Riding.

HULL PHOTOGRAPHIC SOCIETY.—The first outing of the summer session to Hesse Cliff on Saturday last attracted a good attendance. The President and another undertook to give personal attention to the members present, and much useful work was done. Such advice is just what society outings require to make them profitable, and arouse that attention which will draw the beginner and others to the same place again in the future for more serious work alone. The Hon. Sec. writes us that this is to be the keynote of each trip during the summer, and is worthy of support and imitation by other societies. The summer syllabus includes a long series of outings, and, from the particulars published, they appear to be extremely well organised.

RICHMOND CAMERA CLUB.—"Richmond Park" was the subject of an interesting lecture delivered to the members of this club by Mr. A. A. Barkas on Thursday evening last, the closing meeting of the session. The lecturer called the attention of the members to the large number of interesting objects of antiquity in the neighbourhood, which will sooner or later be destroyed, and which are well worth recording by means of the camera.

DARWEN PHOTOGRAPHIC ASSOCIATION.—The members of this association have decided on holding their annual picnic to Millers Dale and Buxton. Mr. Thomas, who has been secretary to the Darwen Photographic Society for ten years, has resigned the position. Mr. Fred. Dearnley has been appointed secretary and treasurer.

CROYDON NATURAL HISTORY AND SCIENTIFIC SOCIETY (Photographic Section).—On Wednesday, April 26, Mr. J. H. Baldock, F.C.S., gave an interesting demonstration upon "Photographing Small Objects by Artificial Light."

BLAIRGOWRIE PHOTOGRAPHIC ASSOCIATION.—At the monthly meeting in the clubroom on Tuesday evening of last week Mr. W. D. M. Falconer gave a lecture on "Orthochromatic Photography," illustrated by lantern slides.

SOUTHPORT PHOTOGRAPHIC SOCIETY.—The members of this society held a successful concert in the Queen's Hall, Neville Street, Southport, on Thursday evening last.

SOUTH NORWOOD PHOTOGRAPHIC SOCIETY.—On Good Friday this society held their fourth annual excursion to Fittleworth. During the afternoon the presentation of a silver-plated rose-bowl was made to the president, Mr. J. Smith.

SOCIETY OF CHEMICAL INDUSTRY.—Meeting held Monday, May 1. A. Gordon Salamon in the chair. Prof. Chiri Otsuki, Ph.D., read a paper on "The Study of the Action of Hydrogen Peroxide on a Photographic Plate in the Dark," some reference to which is made in "Ex Cathedra." A further paper on "The Influence of the length of time of Development on the Degree of Darkening of the Photographic Plate" was taken as read. A brief discussion followed in which Messrs. T. Thorne Baker, S. E. Sheppard, and others took part.

LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION.—The last meeting of the winter session of this association was held on Thursday, April 27. The President congratulated the members on the success of the meetings held, and the increased vitality of the society.

GLASGOW SOUTHERN PHOTOGRAPHIC ASSOCIATION.—At the Fourth Annual General Meeting of this Association, held on April 25, the following office bearers were elected for the year: President, W. S. Morren; vice-president, Wm. H. Wilson; honorary treasurer, Edward J. Grant; honorary secretary, Wm. A. Frame, 28, Bank Street, Hillhead, Glasgow; hon. assistant secretary, R. Lindsay; council, Messrs. D. Linton, Jas. M. MacLean, D. Horn, J. Keith, Jas. Henderson, and Chas. Young; auditors, W. Milroy and Rob. Young. Any person desirous of joining the association can have full information on application to the honorary secretary.

Commercial & Legal Intelligence

NEWSPAPER Owner Sned.—In the case of the Official Guide Co. v. J. J. Neilly at Dublin last week, an order was made directing the attendance of the defendant for examination with reference to his means. The affidavit of the plaintiff company set forth that the Sheriff returned "no goods" on a judgment obtained against defendant for the sum of £108 9s. and costs. Defendant resided at Torrento, Dalkey, and the debt related to the printing of the "Irish Amateur Photographer," issued from the same place as the "Irish Figaro." An exhibit was made of a dishonoured cheque for £45.

MUCH-PAWNED Camera.—George Werner de Sondelberg, alias Leonard, alias Herne, a photographer, of no fixed abode, was charged, at the Cambridge Police-court, with stealing a camera, valued at £3, the property of Herbert Mason, in December last. The prisoner had applied to a local photographer for work, and had succeeded in obtaining the camera in question for the purposes of canvassing in the country. The detective who arrested him stated that the camera had been pawned by the prisoner, who had eventually parted with the ticket. The same camera had been pawned at the same place several times before. Later he found that the camera had been redeemed by the Rev. C. Joseph, from whom witness eventually received the property. Witness also heard that prisoner had pledged another camera that Mr. Joseph had lent him. The prisoner said he thought the camera had been given to him.

A BRIXHAM Photographer's Affairs.—Charles Edgar Pridham, 5, Fore Street, Brixham, attended a meeting of his creditors at Plymouth on Thursday of last week. The statement of affairs showed gross liabilities of £113 11s. 5d. The assets amount to £35 6s., leaving a deficiency of £75 15s. 5d. Depression in business and sickness are the alleged causes of insolvency. Subsequently, at his public examination at the Stonehouse Bankruptcy Court, before Mr. Registrar McCrea, debtor, stated that he spent from £50 to £60 fitting up his business premises. At first the business was profitable, but did not continue so, owing to the depression in the fishing industry. The examination was closed.

BANKRUPTCIES.—Cecil Montague Stafford, residing at 5, Nassau Place, Leeds, and carrying on business under the style of Cawkwell and Stafford, at 2, Commercial Street, Leeds, photographer, appeared for his public examination at the Leeds Bankruptcy Court on Monday, before the Registrar. The statement of affairs filed by the debtor disclosed liabilities amounting to £634 5s. 9d., and there were no assets. The unsecured liabilities were chiefly due to customers who had paid for photographs in advance and had not had them delivered. The examination was adjourned for a month.

WILLIAM ELLAND, 31, Hill Top Mount, Leeds, and carrying on business at 14, New Briggate, Leeds, photographer, also appeared for his public examination at the Leeds Bankruptcy Court on Monday, before the Registrar. The summary of accounts filed by the debtor showed liabilities estimated at £536 2s. 4d., and assets returned at £178 7s. The examination was adjourned to May 15.

For a simple mountant which will keep for a long time, that suggested by Messrs. Trapp and Munch for their papers may be tried. It is made by dissolving an ounce of gelatine in three ounces of water, and adding fifty minims of amyl alcohol.

The Argentine Government have assumed the monopoly of the manufacture and sale of pictorial postcards, and all prepared by private persons will be confiscated. It is to be hoped that this may bring revenue to the empty coffers of this distressful country.

The following advertisement appeared in last Monday's *Times*: The Seventh Messenger to the Potentates, Priests, and Ministers of all nations. Away with the Abominations. Prepare the People for a Special Manifestation of THE LIGHT." "Probably an advertisement of a new firm of electricians," suggests the *Globe*. The makers of the mercury-vapour lamp had better see into the matter.

MAKERS' FORMULÆ.

To the Editors.

GENTLEMEN,—I am obliged both to Mr. Tennant and "Chemist" for their kindly endeavours to enlighten my ignorance, and I can now understand the subject and appreciate the cause of the chaos.

As regards Mr. Tennant's remark about not looking a gift horse in the mouth, this is surely uncalled for, and although I am always grateful when anyone gives me a good formula I am still more grateful when it is expressed in such a way that there is no doubt in my mind as to what is meant, so that if I find that it does not work satisfactorily, according to my standard, I know that it is not my fault for having made it up in another manner than that intended by the author.

With regard to Mr. Tennant's conversion, I fail to see how he gets 195 gr. and 97.5 for the chloride and lead respectively.

Certainly the facts brought forward merely emphasise my remarks as to the necessity for standardisation of our formulæ.—Yours faithfully,

ARTHUR PEAKE.

London, E.C.

To the Editors.

GENTLEMEN,—I trust that you will excuse my asking for a little space to comment on part of "Chemist's" letter in your issue of today. In the first place, I would desire to say that (probably from my error) the amount of sodium sulphite and that of lead acetate should be 175 and 87.5 grains respectively, instead of 195 and 97.5, as given.

I am utterly at a loss to see why for practical purposes the formula A of Mr. Peake should not be considered as containing 10 per cent. of pyro. "Chemist" seems to believe that the ounce measure of water contains 480 grains in weight. Of course it does not. It should hold one ounce avoirdupois of water of the standard quality and under the standard conditions. Of course the formula will not give a grain of pyro for 10 minims of the solution, but it will give an ounce for 10 ounces of the solution, or a gramme for 10 c.c.s., and that is what we require—if we choose to mix incongruous matters, the fault in the result is ours.

Next, as regards the comments on your "Ex Cathedra," the approximate difference between the litre and 1,000 c.c.s. is as you give it*; and will be found so on reference to the Statutory Order in Council, which has the force of law. A reference, too, to the definitions given in another Order in Council will show that the definition of a litre does refer to water at the temperature of 4 deg. C., and also prescribes the barometric pressure. It is true that the General Council of Medicine has authority to "publish a list of medicines and compounds, together with the true weights and measures of which they are mixed," and that they have used a temperature of 60 deg. F. for marking volumetric measures; but it seems doubtful whether a chemist is entitled to use such measures for any purpose of sale to the public unless they are stamped by the inspectors of the Standards Department. Probably the question will never arise, as any difference between the standard of the Medical Council and that of the inspector will be negligible. But perhaps some inspector may insist on earning his fees for verifying the weights and measures, if used otherwise than for making up prescriptions.—I am, Gentlemen, yours faithfully,

April 28, 1905.

J. F. TENNANT.

* It amounts, in other words, to about $2\frac{1}{2}$ minims in a litre.

THE P.P.A. ASSISTANTS' CERTIFICATES.

To the Editors.

Gentlemen,—I have no great desire to be controversial on the point, but would like to question Mr. Groves' estimate of the percentage of outclassed operator assistants. One per cent. is surely too small a proportion to represent this number, and, to my mind, would more accurately apply to the class drawn from the "hundred or so" studios for whom first-grade certificates, as the scheme now stands, are available only.

It is reasonable to suppose that in a trade, hitherto unclassified, there must be a large section of workmen long past their apprenticeship who are neither master photographers or (excuse me) "Extra first-grade" operators to whom a certificate, which covers a five years' term and qualifications that are almost secondary, cannot apply adequately. Their numbers and ability, it may be assumed, indeed, are such as to make them more genuinely representative of the "operator and assistant" employee than any other that is provided for in the certificates scheme.—Yours faithfully,

May 2, 1905.

Scot.

FOCUSsing SCALES AND DEPTH INDICATORS.

To the Editors.

Gentlemen,—I see that Mr. J. H. Taylor, in his article on focussing scales and depth of field, unduly credits me with the suggestion of a mechanically magnified scale. May I be allowed to correct this, and at the same time to explain the true facts with regard to the development of such depth-indicating devices?

The scale and indicator showing depth was first invented and published by myself in 1897 in "The Amateur Photographer," and since then the combination has been independently re-invented at least three times in three different countries—once by an American gentleman, whose name I forget; once by a member of the firm of Carl Zeiss; and once by Messrs. Beck. In all these cases the invention related to a scale for actual use on the camera, but, though various individuals made and applied scales according to my original instructions, it appears that Messrs. Beck alone attempted the commercial application of the invention.

The idea of magnifying the scale mechanically was, I believe, solely due to Mr. Bolas. He suggested this improvement in an article he wrote not long ago on my scale and index, and I supported his ideas as very practicable, though personally I do not feel the want of any magnification. The divisions on Messrs. Beck's "Cornex" index are minute, but this is owing to the fact that they have adopted a very small circle of confusion as the basis of their calculations. If 1/100 in. is adopted, the divisions are not too close for ordinary purposes, while a smaller circle of confusion is readily allowed for.

The indicator and scale to be used as a substitute for depth tables, as described by Mr. Taylor, is an excellent device, and I have had it in use for a long time. It is exactly on the same principle as the camera indicator, but it is made on a much bigger scale. It is a most perfect substitute for the usual depth tables, which are usually more confusing than helpful. I would, however, point out to Mr. Taylor that he has not tackled the problem from the easiest point of view. It is far easier to make an indicator than a very fully divided scale, and the best plan is to have one scale and separate indicators for lenses of different focal lengths.

I enclose a set of indicators with scale for your inspection and use. I think you will find that they convey far more information than the most elaborate table of depths, and that they are far more convenient in use. The circle of confusion allowed for is 1/100 in., and if it is desired to allow for, say, 1/200 in. it is only necessary to reduce the ratio number of the stop in like proportion. Thus, the depth with $f/8$ at 1/200 in. confusion is equal to the depth with $f/4$ at 1/100 in.

It is advisable to warn users of these scales that the results are not in all cases accurate. They are accurate in theory only. The calculations are based on the assumption that depth varies solely with aperture and focal length, which assumption is very wrong with many lenses, and quite possibly is incorrect with any. I understand that Messrs. Beck found it necessary to modify the divisions of their index to bring the results into accordance with facts instead of theory. A critical examination of the "Cornex" index will show that the divisions do not agree with theory, for the distance of the $f/8$ mark from the arrow is only one-third, instead of half the distance of the $f/16$ mark. The indicator must be very carefully adjusted to the particular type of lens it is to be used with, and this is a very unfortunate hindrance to the universal adoption of these useful devices. Depth tables, and depth calculations generally, are deceptive for the same reason, and indeed with some lenses they are useless. Still they are of some value, but they are by no means so easily applied as the scale and indicator described by Mr. Taylor.—Yours faithfully,

April 28, 1905.

C. WELBORNE PIPER.

Answers to Correspondents.

- * All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.
- * Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- * Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.
- * For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington-street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED :—

- S. Carter, Helston, Cornwall Road, Walmer. Photograph of Group of Officers of the 26th Middlesex R.V. (Artists). Photograph of General Parade of Artists Volunteers at Deal Barracks. Photograph of Group of Warrant Officers, Staff Sergeants, and Sergeants of the R.M.L.I. and 20th Middlesex Volunteers.

- F. Holmes, Castle Hill studio, Castle Street, Mere, Wilts. Two Photographs, "Meet of the West Wiltshire Foxhounds at Alfred's Tower, Stourhead, Somerset."
- R. P. Gregson, 37, Church Road, Lytham. Photograph of Stephen Bloomer.

CRYSTOLEUM GLASSES.—I am in want of some crystoleum glasses, set in plush frames, that show no raw edge of the glass, but are turned in. I have tried at several wholesale dealers, but cannot get these, although I have seen them in photographers' windows in neighbouring towns.—CHRYSTO.

The Art Photo Supply Co., Steelhouse Lane, Birmingham, or H. Cornthwaite, Dale End, Birmingham, will probably be able to supply what you require.

MAKING SOLUTIONS.—Kindly tell me what you consider the best method of making up a saturated solution of, say, crystal borax, so as to reach as nearly as possible the exact point of saturation, and thus prevent so much of it crystallising in the bottle, as I find it very difficult to re-dissolve it, as the bottle will not stand hot water.—BORAX.

Place about 1 oz. of borax (i.e., a little more than the water to be afterwards added will retain in solution when cold) in a jug and pour over it 10 oz. of hot water. Stir up thoroughly with a spoon or a glass rod, or by pouring backwards and for-

wards from one jug to another, until it dissolves. On setting aside to cool you will have a fully saturated solution, and you can see that this is so by the deposit of crystals thrown out of the solution on cooling. Consult the solubility tables in the "Almanac" for the quantities of salts.

WALTER SMITH.—8, King Street, St. James', S.W., is the address of Christy's.

FRENCH PASTELS.—I should be very pleased to hear through the medium of your paper where I may procure the French pastels mentioned last week by Mr. Arthur Whiting.—J. F. SLACK.

Reeves and Son, artists' dealers, Moorgate Street, London, DYES AND TINSEL.—Will you kindly inform me what liquid is the best to add to aniline dyes to prevent same from fading in P.O.P. print miniatures, especially the red colours, which usually fade on bromide paper? (2) What gum solution is used for sticking tinsel on postcards? (3) The best house for buying tinsel?

(1) None. You must choose fast colours. State your wants to one or other of the houses dealing in dyes. (2) We should say a mucilage of gum arabic would answer, or a waterproof glue, made by dissolving gelatine in water until it softens, removing it before it has lost its original shape, and dissolving in ordinary linseed oil on a gentle fire until it is of the consistency of jelly. (3) Two firms are:—Louis Birnsthing and Co., 26-27, Hanwell Street, London, E.C., and George Kenning and Son, Little Britain, London, E.C.

STEREOSCOPIC.—Would you kindly answer the following? On a camera for 5 by 7 plates I have a front board of $3\frac{1}{4}$ in. wide.

(1) Can I mount two lenses on it to have stereoscopic views and effect? (2) What would be the result if the lenses are not enough separated—say $2\frac{1}{2}$ in. from centre to centre of lenses? (3) Is there any other way to obtain two views on a plate with one lens without shifting the camera by inside or, may be, outside arrangements?—A. LEVY.

(1 and 2) Perhaps. The separation may be as little as $2\frac{1}{4}$ in.—centre to centre of the lenses—but it is well to have the lens-board at least wide enough to bring each lens opposite the centre of the $3\frac{1}{4}$ by 5 plate, i.e., the centres must be $3\frac{1}{4}$ in. apart. (3) Except a special tripod head to shift the camera to and fro 3 in. or more, there is nothing except an arrangement consisting of a pair of mirrors hinged at a large angle and placed to one side of the camera lens. The view is photographed by reflection from the two mirrors, and the angle is adjusted to give the necessary separation on the plate. This device, very neatly made, is sold as the "Stereoscopic Transmitter." See our advertisement pages.

STICKING PAPER TO METAL.—Your formula for a gum to stick paper on metal I cannot make to work, as the paper peels off after a few days. Does the tragacanth require crushing to a powder? And should the arabic be added afterwards?—F. B. GOWLAND.

We must confess not to have tried the particular formula, but the best way to make it would be to use both the gums in the form of powder; moisten the tragacanth with methylated spirit, and then add the water and stir in the gum arabic, and heat gently, or warm water might be used. We should think that the addition of a little acid, if permissible, such as acetic, would be advisable, as this would slightly etch the metal and cause the paper to adhere better. Very frequently a label will stick well if the metal is slightly roughened with pumice-stone powder; and the addition of a drop or two of glycerine to the mountant is also an improvement, as it prevents it becoming absolutely bone dry.

DESIGNS ON COPPER.—Could you kindly state if carbon is the best process to use for reproducing designs on copper plates and

cylinders for engravers to work, suitable for pottery printers, etc., or is there any better method adopted?—REX.

Carbon is not suitable, as the gelatine film clogs the engraver's tool. The plate should be sensitised by a fish glue or albumen formula, as used by the half-tone etcher. There are numerous formulae. You might use that in our "Photo-Mechanical Notes" for January 27 last. Better get a handbook on the half-tone process.

RETOUCHING.—The photographs herewith enclosed are prints from two poor quality negatives taken by an inexperienced operator. I am a first-class operator, but somewhat doubtful of my retouching. Would you kindly pass your opinion on my work? Should I be able to take a position as retoucher? Time taken on each negative, twenty minutes.—G. H.

If you are a first-class operator why did you not show your retouching upon your own negatives? We consider your retouching quite good enough for any firm that only allows twenty minutes for a cab.-vig., but a first-class operator should surely also be thoroughly up to the best quality retouching. Quickness is not everything, and the leading houses allow at least one hour for this size, and many firms make no stipulation as to time, if the retouching is conscientiously and artistically done. Considering your retouching from a high-class standpoint, it is decidedly weak, for you remove character too much, and simply slur over the faces. There is no quality and properly blended texture. A few lessons from a really first-class teacher would be of benefit to you. You might also submit to us a specimen of your retouching executed on your own studio-taken negative, and printed on glossy P.O.P. to show detail.

H. H. (London).—You have done right in obtaining a written assignment of the copyright, and in the event of infringement you can take action for damages and penalties. Both the Professional Photographers' Association and Copyright Union will assist their members. The photographs need not be marked "copyright."

COPYING OLD PHOTOGRAPHS.—I have several old photographs to copy, but cannot get them evenly lit or the margins quite straight and parallel in the results I have obtained. Can you give me some information as to the best method to set about the business?—M. BLUNDELL.

To secure good reproductions of old photographs, it is necessary to first have the originals quite flat, and the camera must be so adjusted that the focussing screen, camera front, and the support on which the photograph to be copied is pinned are all quite parallel and square one with another. The fact that your copies are crooked proves that you did not attend to this detail. The uneven lighting can only be remedied by trial and error, as you do not say what your source of light is. We should have thought that as you have a studio you could have obtained perfectly even lighting by daylight. If you want to copy the prints by artificial light it will be necessary to use two good oil or gas lamps (incandescent preferred), one on each side of the photograph, and shielded from the lens. A slow or photo-mechanical plate, with or without a blue screen, will give you the best results if the prints are at all faded.

BOOK ON PHOTO-MICROGRAPHY.—Will you kindly inform me where I can get a good book on photo-microscopic work, and the price of same?—E. M. P.

"Photo-Micrography," by J. H. Jennings, 3s.; or "A.B.C. of Photo-Micrography," by W. H. Walmsley, 5s.

H: M.—We understand the business is in the hands of the liqui-

dators, but it is possible that some money is recoverable, as the business has been conducted throughout in a shady way.

FADE.—It is impossible to state definitely what is the actual cause of the fading, but it is certainly due to sulphur compounds of some kind. It has very much the appearance of a print which has been treated with a combined bath containing lead.

BOOK ON STUDIO.—From where can I obtain "Lighting in Photographic Studios," by P. C. Duchochois? Can you supply me?
—R. HALL.

No. You can get it, post free 1s. 1½d., from Messrs. Dawbarn and Ward, Limited, 6, Farringdon Avenue, London, E.C.

INFRINGEMENT OF COPYRIGHT.—I shall be pleased if you can give me any information upon the following facts. Last September I arranged with a photographer in the town to have four pages of advertising matter in a guide, and at the same time arranged with him to take any photos I required for the same book, the photographs to be paid for by myself, and I had to allow it as a contra account off the pages of advertisement. This I did, and received a receipt for £1 for taking the said photos. I told the photographer he was to refer any one to me for publication, as I wanted them solely for my own book, and that I was making them copyright, and I was to receive a commission on photos sold to any one on the said pictures. I copyrighted the two pictures, and a few days ago found them published in another guide. The pictures are those taken for me, as no other photo has been taken, and the names in some places are spelt as my first issue of postcards. I enclose book for your perusal. Please refer to pages turned down in guide. I shall be pleased if you can enlighten me at all upon the matter.—NIL DESPERANDUM.

If the facts be as stated, you have a clear cause of action against the infringer of your copyright for penalties, damages, injunction restraining further sale, and forfeiture of all copies, blocks, etc.; also against the photographer. We should advise you to put the matter in the hands of a solicitor well versed in copyright law.

LENS FOR ENLARGING.—I am anxious to make enlargements by incandescent light from small negatives (about 2 in. by 1½ in.) to whole-plate size and 12 by 10. Will you please tell me the best lens to use for the purpose? Can you recommend the Goetz Double Anastigmat Series 1B, as advertised in the "Almanac," p. 377, and, if so, which No. of same ought I to get?—T. S.

Any good modern anastigmat with a large working aperture will serve your purpose. This type of lens is much to be preferred for the "portrait" form usually recommended for enlarging, as it has a flat field and covers well to the corners without stopping down. The lens you mention will do very well indeed, and as the ultimate size of the enlargement has nothing to do with the size of lens employed, No. 000 of the Series 1B, covering a plate 2¼ by 1½ at full aperture, should meet your requirements.

STUDIO QUERY.—May I ask you to be good enough to advise me as to the best design and construction of a photographic studio, which I am about to build in my garden? Please supply following particulars:—Would 20 ft. by 10 ft. be a convenient size? Height of eaves and ridge. Position and amount of glass. Position of dark-room. Position of door, etc. And generally as to the best way of going about it.—J. F. LLOYD.

You do not say whether you require the studio for amateur or professional purposes. If the latter, we should advise its being 5 ft. or 6 ft. longer, if you have the space at your disposal, also a foot or so wider. As the building will be near the wall on one side, we should say that the ridge-roof form

will be the best, but with the one side only—the N.W.—glazed. If the studio is made only 20 ft. long, 4 ft. or 4 ft. 6 in. at either end, top, and sides may be opaque. If longer, that may be increased in proportion. The dark-room may be at the southern side, and the door at any convenient part. We should advise you to get Bolas's book, "The Photographic Studio: a Guide to its Construction, etc." It will give you a lot of useful information. It is published by Marion and Co.

Will Mr. J. H. Taylor kindly send his address, as our publishers hold a letter for him.

JOHN MADDISON.—If you will name the year, we can identify the picture, but it is certain that the copyright is not ours.

RETOUCHING.—Kindly give your opinion of retouching of enclosed photographs, and state where same might be improved.—M. S. M. B.

Your touch is pretty clean, but much too similar on all the faces. No difference is made between men and women, and we note that none of the faces are of old people—the best possible to show the skill of the retoucher. The men look too hard and ill through the close working, and would have had a more natural and softer appearance if you had used a bolder grain. The evening-dress study of young lady is your best effort, but avoid getting such a decided line of lighting down the nose—soften it off on both sides. Only two of the prints show the unretouched as well as the finished picture, and these we comment upon specially. The young sitter is fairly good, but very flat about the nose and chin. Look to your high-lighting more, and do not sterilise your efforts with mere stipple. The nose is almost flush with the cheeks, and the chin a sad nonentity—do not make her assume a weakness if she has it not. The elderly lady is grossly, or rather ethereally and unreasonably flattered. *She* may like it, but her own coterie of dear friends must snigger! Your treatment of the neck, although very much rejuvenated, is commercially warranted; but the entire removal of the shadows from under the eyes, the corners of the mouth, the mark from nostril to lips, and the dimple in the chin are quite inexcusable. The lady is fat, probably fair, and most decidedly forty—then why make her an insipid gazelle of uncertain age?

THE LIEGE EXHIBITION.—The King of the Belgians has arranged to visit the exhibition, including the British section, on the 11th inst., and it is expected that the whole of the exhibits will be ready by that time for His Majesty's inspection. The incomplete state in all sections, including the Belgian section, on the opening day, was caused by the block on the Belgian railways, which during the last few days have been severely overtaxed, in the direction of Antwerp, Brussels, Charleroi, and Aix la Chapelle, and exhibitors were unable to receive their goods. The lines are now clear, and great progress is being made every day in installing the various exhibits.

EX CATHEDRA.

Cyanide Poisoning. Three deaths have been recorded during the past few weeks of poisoning by cyanide of potassium. Now another has been added to the list. In the previous cases the poison was taken internally; in the present it was not, and this gives to a greater photographic interest. From the very brief report now before us, it seems that the victim was an amateur photographer. Some week or two ago, when using a solution of the cyanide he allowed it to enter a cut finger, where it apparently set up blood poisoning, which proved fatal in spite of medical treatment. Except by wet-plate workers, and, on the rare occasions when the cyanide of silver, or Monckhoven intensifier, is employed cyanide does not enter into present-day working methods. And, indeed, throughout the many years when cyanide has been used as a fixing agent by every photographer in the land, we cannot recollect a single fatal case of the poison entering through a wound. We know of many serious results—among both photographers and electro-plate workers—where weeks of pain have been caused by poisoned hands and fingers, but the poison has never, so far as our recollection goes, had a fatal effect. Frequently, years ago when working the collodion process we have had the poison enter a scratch or abrasion of the skin without results, but we always took time by the forelock. As soon as we felt the smarting—which occurs always when the cyanide comes in contact with a wound—the part was put under the tap for a minute or two, and then the place well sucked for a few minutes so as to get out all traces of the poison before it had time to diffuse itself, and, of course, being taken that no more got in during the day's work. One may often have a slight scratch or abrasion of the skin and not be aware of the fact until

the cyanide reveals it, then the best course to pursue is that just mentioned. If, however, the smarting should be renewed the place should again be well sucked at frequent intervals, and finally poulticed for some hours. If this be done very rarely will any ill-effects follow.

Death from Bichromate of Potash.

Although bichromate of potash is so largely employed, and for so many purposes, it is seldom that we hear of a death from it. Last week, however, an inquest was held at Hammersmith on the body of a man who had swallowed some solution of it in mistake for beer. It appears from the evidence given at the inquest that he was told he could help himself to some beer from a bottle in a certain cupboard. It happened that there was a similar bottle in the cupboard containing the bichromate, which a french-polisher, who used it in his work, had placed there for safety. The deceased, in mistake, swallowed that, with fatal result. Coroners, when a death occurs from a substance which is not on the schedule of poisons, are moved to make strong comments on the fact that it is not. Had it been so in this case, as in many others of accidents with other unscheduled poisons, the result would have been the same, whether purchased from a pharmaceutical chemist, or bought at an oil shop. If from the former the purchaser would probably have to pay two or three times the price, for a similar quantity, that he would at the latter. The chemist's packet might be labelled "poison," or it might not, for we have frequently purchased the salt at a chemist's without the packet bearing the warning red label and legend. Even if the packet be labelled, what safeguard is that against accidents when the salt, whether bichromate or any other, is made into solution for use, for that is the only state in which it can be employed? It is with solutions that accidents occur.

Fallacies of Scheduling.

We remember an accident similar to the above, which occurred a few years ago in the warehouse of a firm of druggists' sundrymen, where a solution of bichromate of potash was drunk in mistake for beer, also with fatal result. We also remember a case in which a man, for some ailment he was suffering from, had been recommended to take a mixture of a pennyworth of each of two or three different things. Amongst them was a pennyworth of bicarbonate of potash. In mistake for this the "store chemist" supplied the man with bichromate of potash. The packet was not labelled poison; the man made up the mixture and took some, with the result that he became seriously ill for a long time, but ultimately recovered. He then brought an action against the "store chemist," and recovered very substantial damages—some seventy or eighty pounds, if our memory serves us correctly. These

are notable cases we call to mind of poisoning from bichromate of potash taken internally. Although it is an unscheduled poison, all were accidental and would not have been avoided if the salt had been scheduled except, perhaps, in the case of the chemist's carelessness. Most of us know the effect that the bichromate has upon the hands of some persons who use it largely in photography, but that is quite a different thing from the action of the salt taken internally. A Bill is being promoted in Parliament to amend the Pharmacy Act, and adding to the list of poisons, used for industrial purposes, so that they can only be sold in small quantities by pharmaceutical chemists. Ostensibly this is for the safety of the public. For years the attempt was made to get carbolic acid added to the scheduled list of poisons, and at last with success, so that it can now only be sold by pharmaceutical chemists. Notwithstanding this there are at the present time, if one may judge by the reports of inquests held, more suicides by carbolic acid than by any other poison, possibly more than by all the other poisons put together.

For Bichromate Workers. While we are upon the subject of bichromate, we may quote the recommendation of Dr. Schleich, in the current "Moniteur," of a calcium soap containing wax as a protection against skin-poisoning by bichromate. The preparation of the soap is carried out as follows:—150 grains of pure neutral soap is dissolved in $3\frac{1}{2}$ ounces of water on the water-bath, and $3\frac{1}{2}$ ounces of wax added with constant stirring. After thorough mixture and cooling, 170 minims of strong ammonia are added, and then $3\frac{1}{2}$ ounces of lanoline or other similar fat. The mixture is diluted with water to bring it to a suitable consistency, and can then be stored for use. Dr. Schleich advises first washing the hands with ordinary soap, soaping them again, and then rubbing in the paste made as above. On the hands being finally rinsed with water without wiping on a towel, a protective layer of wax is left on the hands. At the close of work the hands are thoroughly washed and dried on a towel, whereby the wax is removed. The procedure is stated to give a much more convenient protection than collodion or rubber gloves, though why Dr. Schleich calls his mixture a calcium soap we cannot say.

A Further Loss of Thames Scenery.

Lovers of the scenery of the "Silver Thames" will learn with regret that another beautiful spot is doomed. We learn that that lovely estate of some twenty acres with its fine lawn coming down to the river, and studded with cedar trees, known as the Boyle Farm. Thames Ditton, has been sold for building purposes. It is stated that the mansion will probably be converted into a large riverside club, or an hotel, and the old-world garden will be utilised for houses. Horace Walpole often wrote of the beauties of the place, and at one time Boyle Farm rivalled Strawberry Hill as a centre of gaiety. Photographers who wish to obtain pictures of this beautiful spot should lose no time in securing them before it is disfigured by the builders.

Defacing Negatives.

Which is the best way of making a big batch of gelatine negatives, varnished or unvarnished, unfit for printing? The question is one which may come up before the photographer who is clearing out accumulations of exposures, and wants to assure himself that they can never be used to the detriment of himself or his sitters. The natural answer, no doubt, is: Scratch through the film as each negative is discarded.

But that will be found a by no means rapid process, and other expedients, such as removing the film in hot water are quite impossible. A solution of the difficulty, discovered by one of our correspondents when placed under the circumstance we have referred to above, is to dab each negative with a solution of aniline violet dye in methylated spirit. The blotch of colour causes an immediate defacement of the negative, and it matters not whether the film is varnished or not. The dye fixes itself with equitenacity in both cases. In point of rapidity the method is all that can be desired, and its application to even negative that passes out of the photographer's possession, presumably for destruction, is a certain means of preventing any illicit and undesirable use of it.

Points of View.

A new terror for the portrait painter who exhibits at the Royal Academy has appeared on the horizon. We have nerved ourselves to regard with equanimity the indictments of the "Tailor and Cutter," who annually cuts up, with metaphorical scissors, the pictures of the year, and points out the impossibility of the clothes worn by famous people as depicted on the canvases at Burlington House, but now we see by a letter to the "Morning Leader" the votaries of St. Crispin have taken up the running, and the footwear in the picture comes in for disquieting criticism. Here is an excerpt from the letter in question:—"In large exhibit 101, representing King Edward, I beg to state that a village cobbler would be heartily ashamed of left boot of his Majesty, the welt of same throwing whole boot out of balance. Also waist and uppers are clumsy and liable to warp at seams, so destroying effect of whole picture. In 711 ('Sisters') left high heel of well-dressed lady getting into hansom is all sideways. Doubt if same wd be worth repair. Several and a half pairs of boots in this exhibit, every welt disfigured, clicking and finishing bad; neither laces nor lace holes apparent in any. Result: Picture spoilt entirely." We suppose that even if duly qualified tailors and shoemakers were included in the Hanging Committee of the R.A., the hatmakers, milliners, chiropodists, landscape gardeners, boatbuilders, and other specialists would still find cause for complaint.

An Incompetent Academy.

Controversy pertaining to the failings of the Royal Academy continues to rage in the daily press. The "reform party"—an apparently necessary evil indigenous to every well-established and popular institution—casts contumely on the present Exhibition, and Mr. John Cooke, a painter who has exhibited at Burlington House for many years, but whose name does not appear in the catalogue this year, states in the "Express" that "at the present time the minor and applied arts are absolutely ignored by the governing body. There is not an Academician who is a capable judge of an engraving." If this is correct, we wonder what position mere photography holds in the estimation of the august body that presides over the destinies of daubers at the temple of Art in Piccadilly. We read further that "if the Royal Academy were doing its duty to the country there would be no need for the art societies which have sprung up and which are all, directly or indirectly, opposed to the Academy," but are reassured by the admission that "although some of these societies attempt to compete with the Academy, such competition is impossible, for Burlington House is by nature of its traditions and its unrivalled building, almost impregnable. It could easily survive another fifty years of bad management." Exactly, Mr. Cooke. "Ars longa, vita brevis."

Halfpenny photography. There has lately been brought to our notice a photographic public of the very existence of which we were in profound ignorance. How large this public is we have no means of saying, but it is possible that thousands are numbered in its ranks, inasmuch as the complete outfit with which a photographer of this description commences the practice of the art costs but a single halfpenny. Your photographic dealer or chemist is not the person privileged to transfer these goods from the maker to the consumer. That duty, we find, is discharged by the sweet-shops. You ask for a "halfpenny photography," and you get a big envelope on which it is positively stated that "D. Mac's Young Photographer contains complete printing frame, sensitised paper, and chemicals. Will copy portraits, leaves, ferns, etc." Inside you discover a pasteboard printing-frame (with glass), two dirty bits of albumen paper about postage stamp size, and a pinch of white powder (hypo). We will say this much for the outfit: the assurances on the envelope are not belied, and when you tire of copying ferns, another halfpenny will purchase a very good negative of the Tower Bridge, whilst for a penny you can get three quarter-plate pieces of "Clerkenwell" P.O.P. in a wrapping strongly resembling that of a standard brand of gelatine printing-out paper. We cannot for a moment suppose that the wrapping or the designation of the paper indicates the emission of the packet from either of two great firms, however persistently the policy of "popular photography" may be pursued. Indeed, the instructions in the packet are too impractical in places for anyone to attribute them to an experienced photographic trader. We are told that, after washing, the picture "is ready for mounting, which must be done with a little paste when your picture is damp, so that you have no grease on it."

Photographers in embryo.

From inquiries made among our juvenile acquaintances we find that the photographic packet is a prized article. Sir Martin Conway, whom we quoted last week on second-hand photographs, will be interested in learning that a negative and printing frame (halfpenny each, new) may fetch as much as a penknife with two broken blades if not much the worse for wear. The technics of the art, too, we find, are not all in the literature. A young friend informed us that you could finish the pictures with salt instead of the chemicals. Her authority for this statement came not from Sir William Abney, as we had expected, but from "a boy in the backs." A good deal has been said at one time or another about the way in which the deluge of cheap cameras has made purchasers of more expensive apparatus. We are not so sure that there is a very great deal to be said on that score, but at any rate there is still another under-world of young boys and misses, photographers in embryo, who in a year or two, perhaps, will be purchasers of cameras and accessories.

The "Watkins Factor." The recent discussion as to the confusion which may result from the improper use of the term "development factor," has brought us the intimation from one or two writers of their intention to employ this term only in the original sense of Hurter and Driffield. Mr. Kenneth Mees and Messrs. Newton and Bull write that for the multiple or "times" number, as used in the Watkins system of time development, they will use the expression "Watkins factor." Perhaps other writers on development may find it convenient to fall in with the suggestion which seems as good as any other.

PRINTING PROCESSES.—II.

PLAIN OR SALTED PAPER.

As regards the sensitising of the salted paper, one of two procedures may be adopted. Both yield equally good results, though the one gives a much more sensitive paper and one that is suitable for somewhat hard negatives. The only disadvantage is that the paper must be used within twenty-four hours of silvering. The other should be adopted if the sensitised paper is to be kept, and it may be taken for granted that it is preferable for all-round work, because we can, under special circumstances, obtain all the advantages of the former by subsequent treatment.

The first method is by the use of ammonio-nitrate of silver, the second with a mixture of silver nitrate and citric acid. Whichever process is adopted precisely the same method should be used for applying the silver solution as was advised for the sizing, namely by brushing on. This process has the advantage of giving paper of constant quality, which is due to the fact that a given quantity of salt and a given quantity of silver is apportioned to a given area, and one is thus absolutely independent of any outside influences, such as humidity, or variation in temperature or errors in time of floating the paper on the baths. The floating method has certain disadvantages. A considerable quantity of silver bath has to be made up, far in excess of that actually required, and further, every sheet floated on the same abstracts a certain amount of silver. Hence it follows that unless the amount of silver in the bath is frequently and quantitatively estimated, the sheets of paper must be floated for an increasing time, with the consequent greater penetration of the solution into the fibre of the paper, and a great variation in the results obtained. The care of the silver bath is a trouble, and as the bath soon becomes contaminated with organic matter, it has to be sunned and filtered, and entails, in the end, far more trouble than the method we have advised.

It is unnecessary to enter into the theoretical calculations as to the amount of silver required to give us an excess of silver nitrate, but for the same area of paper as we mentioned in the directions for sizing, that is 480 sq. inches, we require practically forty grains. This quantity may, of course, be reduced or increased as the operator, taught by experience, thinks fit, but the above quantity yields a very rich printing paper, giving deep tones that cannot be obtained if a much weaker bath is used. There is also another fact which should induce one to use a strong silver solution, namely that it instantly forms a coarser grained silver chloride, which has but little tendency to sink into the fibres of the paper.

As already stated, if the paper is to be kept, it is advisable to add some citric acid, and the longer the paper is to be kept the greater must be the amount of acid; practically it should amount to one third of the weight of silver nitrate, so that our bath will then be:

Silver nitrate	40 grains
Citric acid.....	13 "
Distilled water to	$\frac{1}{2}$ ounce.

and this should be spread rapidly and evenly over the above named area of paper, precisely in the same way as described for the size. As soon as the surface moisture disappears the paper should be hung up by wooden clips to dry.

The ammonio-nitrate solution has one disadvantage, and that is that if there is much ammonia in excess, the silver chloride will be dissolved, and therefore will have a ten-

dency to sink into the paper. This trouble may be overcome by the following well-known plan:—Dissolve the silver in about three-fourths of the total bulk of water, divide into two portions, to one add liquor ammonia fort .880 drop by drop till the brown precipitate first formed is redissolved, then add the other half of the liquid to this ammoniacal solution, stirring all the time, when generally a perfectly clear solution will be obtained, if not, an additional drop or two of ammonia will clear it up, and then make up to the given bulk with water. Of course the citric acid is omitted, as this serves no purpose now. It is as well also to point out that if this formula is adopted, the ammoniacal silver solution must be brushed on—the paper cannot be sensitised by floating.

As exactly the same result can be obtained by fuming the paper, sensitised with the acid solution, with ammonia, and this entails no more trouble than is involved in putting a little solution of ammonia or a lump of carbonate of ammonia (preferably the latter) in the bottom of a box, pinning the paper to the lid and leaving for a little time, say from five to ten minutes, the ammoniacal-silver method can be dispensed with.

Various other acids, such as tartaric, oxalic, and less known organic acids have been suggested as substitutes for citric, but there are practical objections to all. In the case of tartaric, crystallisation is very apt to take place on the surface; oxalic has inferior preservative powers; the less known organic acids are much dearer, and act no better if as well as citric. That some variation in printing quality may be obtained by the use of these, however, cannot be denied, but their use is more interesting theoretically than practically.

It must not be supposed that because we have given a particular formula, that others will not be found successful. Any soluble chloride may be used, and it has been claimed by some that variation in the final tone of the print is obtained by variation of the chloride. The changes may, of course, be rung through the alkaline haloids, or the earthy haloids, such as calcium, barium, or magnesium and to those who wish to experiment there is a wide field open here but it would be as well to point out that the proportion of actual chloride must be calculated; that is to say, it must not be forgotten, to take one example, that 100 grains of barium chloride

will only contain 29 grains of available chloride, as against 70 grains in 100 grains of ammonium chloride.

There are, however, two possible additions to the salting solution which are extremely valuable, and they should not be neglected as by their use the variation in gradation is enormously increased. The one is sodium phosphate which flattens the print considerably—that is, extends the scale of gradation; the other is a chromate—either potassium chromate or bichromate or the ammonium or calcium chromate may be used. Any of these shortens the scale, so that even the flattest negative may be made to give a rich contrasty print. The exact amount of either must, of course, be determined by experiment, but practically 0.02 per cent. of ammonium bichromate shortens the scale by one-third; with the phosphate a much greater quantity may be used amounting even to 5 per cent. of the weight of chloride.

Changes may be rung on the sizes also. Albumen should not be used, nor caseine, but gelatine and agar agar may, and the latter in particular is very satisfactory, as it keeps the salts well on the surface of the paper. This it does for the reason that it does not form a solution but a jelly which has to be worked into the paper. It is more trouble to apply and make, but this will be of minor importance to anyone who wishes to use it. The best method of preparing this size is to soak 5 grains of agar-agar in one ounce of water for an hour, and then boil for ten minutes, filter whilst hot through fine muslin or nainsook and allow to cool. If it is desired to coat the paper with this as it is, the solution must be used whilst fairly warm, and the coating must be done near a fire; but it is far preferable to allow the solution to set to a jelly and then break it up by squeezing it through fine muslin two or three times. The given quantity is then worked on to the paper with the brushes until it presents a uniform appearance; naturally, the chloride and citrate must be added to the warm solution.

If gelatine is preferred, then the size may be prepared by merely replacing the arrowroot in the formula we have given by an equal weight of gelatine, soaking in the water for an hour, then dissolving by the aid of a water bath. It is easy to apply, only it must be used warm, and unless the brush is rapidly worked, it sets before it is possible to break all the innumerable little bubbles which form.

MODERN CHEMISTRY FOR PHOTOGRAPHIC WORKERS.

II.—THE IONIC THEORY AND DISSOCIATION.

We have seen that if a substance is dissolved, we may consider that the molecules exert a definite pressure by reason of the way in which they are continually hitting against the walls of the containing vessel.

And we have further seen that we may measure the amount of this pressure, termed the "osmotic" pressure of the dissolved substance, by forming one of the walls of the containing vessel of such a material that the dissolved substance cannot penetrate it while the molecules of the solvent can pass freely through it, and that if we measure it we find that

The pressure of a dissolved substance is equal to the pressure which the substance would exert if it occupied the same space in the state of gas.

And we have seen that, according to Avogadro's law, equal volumes of gas at the same temperature and pressure contain the same number of molecules, so that if the gas in a bulb full of oxygen weighs sixteen times as much as if the bulb were full of hydrogen, we assume, not that there are sixteen times

as many molecules, but that each molecule is sixteen times as heavy.

The Pressure of Elements and Compounds in the Gaseous State.

Now, suppose that we take sixteen grams of oxygen and put it in a flask, and measure the pressure which it exerts, we shall get a certain result; and if we next take fourteen grams of nitrogen we shall get exactly the same pressure, and so from 35.5 grams of chlorine or twenty-three grams of sodium; and, generally, any substance whose weight is proportional to its molecular weight will exert the same pressure. When, however, we come to apply this test to compounds, we must remember that the molecule of oxygen, for instance, consists of two atoms, not of one, and the molecular weight will consequently be twice the atomic weight. If the weight of an atom of oxygen, for instance, is sixteen, then the weight of a molecule will be the weight of two atoms—that is, thirty-two. So, remembering this, we may place ammonium chloride in our bulb, and as the formula of this is NH_4Cl , and its molecular weight is 53

we may expect that if we take fifty-three grams of ammonium chloride in the state of gas, it will exert the same pressure as thirty-two grams of oxygen.

Suppose we take two bulbs exactly alike, and in one put thirty-two grams of oxygen, in the other fifty-three grams of ammonium chloride vapour (each at the lowest temperature at which the ammonium chloride will vaporise), and let us heat these two bulbs together in a furnace, the pressure in both of them will go up; but it will be seen that when the bulbs get very hot the pressures in them are no longer equal, but the ammonium chloride is exerting very much more pressure than the oxygen, and when the bulbs are very hot indeed the pressure of the ammonium chloride is practically double the pressure of the oxygen.

Dissociation.

If Avogadro's hypothesis is true, the fact that the ammonium chloride exerts twice the pressure of the oxygen can only mean that the ammonium chloride bulb contains twice as many molecules as the oxygen bulb. And since these molecules must have come from somewhere we are driven to the conclusion that the single molecule of ammonium chloride has split into two, so that we have got

$\text{NH}_4\text{Cl} \rightarrow \text{NH}_3 + \text{HCl}$
Ammonium chloride goes to ammonia and hydrochloric acid gas.

And when the bulb cools the ammonia and hydrochloric acid re-unite to form ammonium chloride. We can write our arrow the other way also:—

$\text{NH}_4\text{Cl} \rightleftharpoons \text{NH}_3 + \text{HCl}$
which is what is termed a reversible reaction—that is, a reaction which goes in either direction according to circumstances. Later on we shall meet other sorts of reversible reactions, and shall find that very many reactions indeed are reversible.

The simple splitting up of ammonium chloride is termed dissociation; but this dissociation is, so to speak, only one stage of a general reaction.

Dissociation in Solution.

We have seen that the osmotic pressure of a substance in solution is the same thing as the pressure of a gas, and that, though we cannot measure it directly with any ease, yet we can measure it both easily and accurately by measuring the amount by which either the freezing or the boiling-point of a solution differs from that of the pure solvent, so that we should expect that, as we find by experiment, weights of substances which are in proportion to their molecular weights, produce equal osmotic pressures when contained in equal bulks of solution. But if we dissolve a salt, such, for instance, as potassium chloride, in water, and measure its osmotic pressure, we find the pressure to be very much greater than that which we should have calculated from this law, and with extremely dilute solutions we may find the pressure to be double what we should have expected to obtain. To this fact we apply the explanation which we found useful in the case of the ammonium chloride—namely, that our potassium chloride has split up into two different molecules, and then we are at once confronted with the question: What are those different molecules? We could write:—

$\text{KCl} \rightarrow \text{K} + \text{Cl}$
Potassium chloride goes to potassium and chlorine.

But the difficulty arises that a solution of chlorine in water has certain well-known properties; it is green, and has a strong smell and bleaching action, while potassium fiercely attacks water evolving hydrogen. And since the potassium chloride solution exhibits none of these properties, it cannot have split up into potassium and chlorine.

Osmotic Pressure, Dissociation, and Electrical Conductivity.

If we attempt to pass an electric current through pure water we shall find that it will allow only an extremely small current to pass, or, as we usually term it, it has an extremely low conductivity. And if we add to the water some substance which has an osmotic pressure which is proportional to the molecular weight, we shall find that the conductivity is still but little improved. If, however, we add some salt which gives osmotic pressures which indicate that dissociation of some sort has taken place, we shall at once find that the conductivity is considerable. This fact would seem to indicate that the dissociated molecules of the salt act as carriers of electricity from one side of the solution to the other.

The State of Molecules in Solution—An Electrical Hypothesis.

And we come now to the necessity of consideration as to the nature of electricity. It is very difficult to see what it is which happens in the interior of a solution, and practically impossible to see what happens in a metallic wire; but, fortunately, an electric current can be led through something in which we can watch the phenomena which occur—namely, an exhausted glass tube. Suppose we take a glass tube and attach it to a pump so that we can remove all the air from it, and then pass a current of electricity through it. To do this we must pass two pieces of platinum wire through the walls of the tube, so that we can connect them to the poles of an induction coil. The piece of wire attached to the positive pole of the coil is called the anode; that attached to the negative pole is called the cathode.

Now, as we pass the current and slowly exhaust the air from the tube, we see the passage of the electricity through the tube as a flickering stream of light. And as the air is steadily reduced this stream of light widens and fills the tube, while more and more light collects around the poles themselves, and especially around that one which is attached to the negative pole of the induction coil, or cathode, as it is named. Suppose now we put a little light fan-wheel in front of the cathode, while the whole tube is glowing with a bright green light, we shall see that the fan will run round exactly as if there was a current of air shot off from the cathode. This experiment, and very many others which have been made in an exhausted tube, are explained by the assumption that there really are exceedingly small particles shot off from the cathode. Professor J. J. Thomson, at Cambridge, has succeeded in estimating the weight of these particles, and he has come to the conclusion that their weight is one-thousandth of the weight of a hydrogen atom. All these particles are shot off from the cathode or negative pole of the tube, and consequently are strongly charged with negative electricity. Positively charged particles are not known to occur of less weight than the atom of hydrogen, so that we may consider that only one sort of electricity really exists, the sort which hitherto we have called negative, and that this electricity consists, like all other matter, of small atoms, which in the case of electricity weigh 1-1,000th of the hydrogen atom, and are termed electrons.

According to this idea a positively charged body is one which has too few electrons; a negatively charged body, too many electrons; and one which is not charged at all will have what one may term the standard number of electrons, which will just balance the rest of the matter round them.

And now let us return to our potassium chloride solution. We saw that this solution would allow a current of electricity to pass through it, while pure water would not; and we have also seen that electricity consists of these little unit charges which are termed electrons, so that the addition of potassium chloride to the water has evidently made it possible for the electrons to pass from one side of the solution to the other. Suppose that we take a solution of copper sulphate and dip

into it two copper plates, and then connect these two copper plates to the poles of a battery. Then, after a little while, we shall find that one of these copper plates is having copper deposited upon it, while the other is losing an equal amount of the metal.

The Ionic Theory of Arrhenius.

To all these facts we may apply a simple explanation, which is called the ionic theory, and is due to Professor Arrhenius, namely, that when we dissolve potassium chloride in water, instead of splitting up into potassium atoms and chlorine atoms, it splits up into potassium atoms with one electron too few, i.e., positively charged potassium atoms, and chlorine atoms with one electron too many, i.e., negatively charged chlorine atoms.

So that if we draw our little electron as a small circle \ominus , we get

the chlorine taking one electron from the potassium atom. We call these charged atoms ions (= movers), and we may write the dissociation equation:—

where the + and — over the K and Cl. denote the electric charges which they possess.

From this we can see at once that the osmotic pressure of a salt solution will depend on the extent to which it has dissociated into these ions. If it has completely dissociated (which only occurs with very dilute solutions), then the osmotic pressure will be double that which would be calculated from the simple formula of the substance, while if it be only partially dissociated, the osmotic pressure will have some intermediate value.

In the copper sulphate solution in which an electric current was passed between two copper plates, we shall have a few

copper sulphate molecules, together with a great many copper and sulphate ions, thus:—

putting two electric charges on both sulphate and copper because if we take copper chloride it must split up into

where the copper needs two charges to balance the two negative charges, one on each chlorine atom. Now, if we picture what happens in the solution when we start to pass a current of electricity, we see that we get one copper plate connected to the negative pole of the battery, and, therefore, having a negative charge, that is, free electrons. These electrons neutralise some of the charges on the copper ions and make these into copper atoms, which promptly deposit themselves (being insoluble in water) upon the copper plate. This leaves a chlorine ion free, which is neutralised by an atom of copper dissolving from the other positive plate, having lost an electron, and so becomes a positively charged atom, i.e., an ion; so that the copper is continually dissolving from one plate and being deposited on the other.

It will be clear from this that since one atom of an element can only carry one electron of electricity, the amount of a metal deposited will vary directly with its atomic weight, and the amount transmitted by the transfer of one gram molecule of any element will be always the same whatever the element may be. Faraday showed this to be the case by direct experiment, and the law forms the basis of the common voltmeter which measures the amount of current passing in a given time by the increase in weight of a silver or copper plate.

Thus we see that the solution of a salt essentially involves an ionisation of the salt, and it will next be advisable for us to consider the way in which these ions behave in chemical reactions.

C. E. KENNETH MEES, B.Sc., F.C.S.

THE WEEK IN HISTORY.

Flexible film in 1856.

In "The Week in History" for April 21 I spoke of the early introduction of the roll-holder into photography in reference to Captain Barr's instrument of 1855. The first attempts to produce a transparent film were made a year later. Probably Alexander Parkes was not aware of Barr's apparatus when he patented, on May 13, 1856, the use of collodion as the support as well as the vehicle of the sensitive silver salt in Scott Archer's process. In 1855 he had patented a mixture of nitrated cotton and other organic or inorganic body as a new material, though he does not appear to have recognised the importance of a light, flexible, transparent material in photography. This photographic patent, which was not finally sealed, consisted simply in the use of a sheet of collodion of sufficient thickness as a support for the prepared collodion.

The "Relandin" Roll-holder of 1855.

Fifty years ago next Thursday M. Relandin was showing the French Photographic Society the model of an apparatus in which twenty-four sheets of sensitive paper could be exposed in turn, being attached to a band of gummed silk wound round a drum. So far as can be ascertained from the description, the feature of daylight loading, which Captain Barr embodied in his slide, did not distinguish the apparatus of M. Relandin. It is true that a commission of the French Photographic Society reported in somewhat grandiloquent language on the invention, and stated that the sensitive papers could be changed with the greatest ease in full daylight, but that reference, I believe, must

be to the change of the twenty-four exposures, which the apparatus contained, and not to the withdrawal of a separate spool. A drawing of the Relandin "chassis" appears in the first volume (1855) of the "Journal" of the French Photographic Society.

Bichromates in Photography—The First Process.

Probably a good many people would not make the bichromate processes of printing as old as they really are if the question were put offhand. In point of fact, the employment of chromium compounds is almost as old as that of silver salts. On May 18, 1839, Mungo Ponton communicated a paper to the Royal Society of Scottish Artists in which he outlined a process for copying engravings, etc., by contact. Bichromate printing is thus very little the junior of the silver processes. Ponton's process was as follows:—"Well-sized paper is to be immersed in a solution of bichromate of potash and dried by the fire; by this it assumes a fine yellow colour, and it may be kept for any length of time without injury, and is always ready for use. When an engraving is laid on this paper, and it is exposed to the sunshine, it passes rapidly, over all the parts through which the rays can act, into a light brown. In this state the photograph cannot be exposed to the light, as all the yellow parts would become brown. If, however, the paper is soaked in water, all the unchanged salt is dissolved out, but that which is browned is not disturbed. We have thus a delicate negative picture, from which positive copies may be taken. If the paper is exposed too long to sunshine it loses colour. A pleasing variety can be made by mixing sulphate of indigo with the bichromate of

flash, the colour of the object and of the ground being different shades of green.”
It may be noted that Ponton did nothing towards our present-day carbon process except to draw attention to the sensitiveness of bichromate in admixture with organic matter. Had he chosen

gelatine as that organic matter, he might have observed the insolubility which is produced on exposure to light. This discovery, of such immense importance in photo-mechanical work, was, however, not made until 1852, when Fox-Talbot published it as part of his photo-etching process. HISTORICUS.

FOREIGN NOTES AND NEWS.

Self Luminous Paints.

Though not strictly within the province of photography, we may give here some formulæ for phosphorescent paints which we find in paper by L. Vanino and J. Gans in the “Journal für Praktische Chemie” (No. 4, 1905, p. 196). The formulæ will perhaps appeal to the numerous class of persons who are constantly asking how to make sympathetic inks, freezing mixtures, and other chemical odds and ends. The authors prepare a self-luminous paint from: Barium sulphate, 60 gm.; 5 per cent. alcoholic uranium nitrate solution, 12 ccs.; 5 per cent. alcoholic bismuth nitrate solution, 12 ccs. This mixture is treated in a muffle furnace for three-quarters of an hour and the contents of the crucible removed in as large pieces as possible. Better results are obtained with a mixture of: Strontium thiophosphate, 20 gm.; thorium nitrate (.5 per cent. alcoholic solution), 12 ccs.; lead nitrate (.5 per cent. alcoholic solution), 4 ccs. The authors have tested the formulæ of a great number of writers, and state those of Lenard, Mourelo, Vanino, and Balmain to be the best. These are as follows:—

Lenard.—Strontium carbonate, 100 gm.; sulphur, 100 gm.; potass chloride, .5 gm.; sodium chloride, .5 gm.; manganous chloride, .5 gm. The mixture is heated for three-quarters of an hour in the furnace.

Mourelo.—Strontium carbonate, 100 gm.; sulphur, 30 gm.; soda, 10 gm.; sodium chloride, .5 gm.; manganous sulphate, .2 gm.

Vanino.—The uranium formula given above.

Balmain.—Calcium oxide (quicklime), free from iron, 20 gm.; sulphur, 6 gm.; starch, 2 gm.; bismuth nitrate (5 per cent. alcoholic solution), 1 cc.; potass chloride, .15 gm.; sodium chloride, .15 gm. heated for three-quarters of an hour.

Another excellent formula is: Calcium oxide, 20 gm.; sulphur, 6 gm.; starch, 2 gm.; potass chloride, .5 gm.; sodium chloride, .5 gm.; bismuth chloride (.5 per cent. alcoholic solution), 1 cc.; calcium fluoride, 3 gm. The authors find that the Heraeus mercury-pour lamp is an excellent light for exciting phosphorescence of the paints.

The Bleaching Out Process of Colour Photography.
Dr. Neuhauss, who has made a special study of this process, has been continuing his experiments, and in the current number of the Photographische Rundschau” gives his latest formula:—

Gelatine	10g.
Water	100ccs.
Methylene blue (0.2 per cent. aq. sol.)	4ccs.
Auramine (0.2 per cent. alc. sol.)	2ccs.
Erythrosine (0.5 per cent. aq. sol.)	1.5ccs. (about)

Special stress is laid on the careful estimation of the quantity of erythrosine solution, this should be added drop by drop, and the moment the mixture begins to assume a red tinge it should be stopped, otherwise the sensitiveness will be lowered. The gelatine solution should be divided into three portions, and one of the dye solutions added to each and then mixed gradually with constant stirring. The sensitiveness of the mixture is increased if it is kept for three to four hours at 35 deg. to 40 deg. C. Ammonia solution, 20 to 30 per cent., used as a preliminary bath before exposure increases the sensitiveness, as does also a preliminary bath of a 1 per cent. solution of chloral hydrate, or this may be added to the dye mixture.

The new cyanine dyes were tested for this process, but proved unsuitable. In order to prepare prints on paper by this process, the opal glass, which has hitherto alone been used as a support, is coated with a rubber substratum, and after printing the gelatine film is stripped and brought into contact, under water, with baryta paper coated with a 5 per cent. solution of gelatine, squeezed and then dried, preferably in contact with a glass or ebonite plate.

Dry Mounting.

M. Briand suggests, in one of our French contemporaries, the following method of dry mounting, which may possibly be useful for highly-glazed P.O.P. prints:—

Shellac, white or yellow	30 g.
Methylated spirit	50 ccs.

Dissolve, and add:—

Gum elemi	3 g.
Canada balsam	5 g.
Methylated spirit	50 ccs.

It takes about twelve hours for the shellac to dissolve; mix the two solutions, and paint both sides of a thin piece of paper and allow to dry; place the paper between the mount and the print, and pass a hot iron over the print, when it will adhere well.

Gradation in Three-colour Work.

As long ago as 1890 the late H. W. Vogel pointed out that, with eosine of silver plates, yellow developed more slowly than blue, and that with slow-acting developers the plates must be developed thoroughly if the more correct rendering of the colours is required. Now Herren Precht and Stenger have been exposing ethyl red plates behind blue, green, and orange screens in strips, then measuring the densities obtained. The screens passed the following spectrum bands:—Blue, λ 415 to 490; green, λ 515 to 580; orange, λ 580 to 680. The developers used were ferrous oxalate and edinol, and the author's charts show that the gradations are not the same, and the longer the time of exposure and the longer the time of development, the greater the variation. The conclusion arrived at by the authors is that any estimated ratio of exposures behind a set of filters only holds good for a given time of development.

Pigment Tissue With Silver Bromide.

In our issue for November 25, 1904, we chronicled the patent of Dr. Riebensahn and Posseltdt for making carbon tissue with an admixture of silver bromide. In a more recent patent they point out that the rapidity of the bromide is considerably reduced, by the pigment probably, through a screening action, and propose to get over the difficulty by using the dyes generally used in the orthochromatising of plates, such as eosine, erythrosine, ethyl red, etc.

Cold Water Starch

In 1903 Julius Kantorowicz, of Breslau, took out a patent in Germany for making starch soluble in cold water by mixing it with alcohol and water and then treating it with soda. This patent he has recently amended, and now uses acetone, or a mixture of alcohol and ether, instead of the alcohol. As an example of the working, two kilos of potato starch are mixed with an equal weight of acetone, and well stirred, and 400 g. of soda lye of 30 degrees Beaumé stirred in, the result being a thick paste. After about an hour the soda is neutralised with acetic acid, and the starch precipitated and washed

with acetone and then dried and powdered. The product thus obtained is soluble in ten times its weight of water, and forms a very adhesive paste. We were under the impression that all cold water starch, as used in the laundry, was made by a similar process, but the patent may be novel.

Chemical Luminescence.

In the "Zeitschrift für Wissenschaftliche Photographie" Herren Trautz and Schorigin detail their experiments on this phenomenon, which is often seen when a plate developed with pyro-soda is immersed in alum solution. It was at first supposed to be some peculiar property of the dry plate, but as early as 1888 Lenhard and Wolf pointed out that this "phosphorescence," as it was called, had nothing to do with the plate, which was confirmed by Neubaus, 1895, and Precht (see B.J., 1904, p. 118). The authors now show that there are a very large number of organic substances which show this luminescence, and suggest that perhaps all organic substances which are oxidisable under 400 deg. will show it. It is entirely due to oxidation, and therefore oxygen must be present to show it.

Non-Actinic Paper.

Namias recommends, in "Il Progresso Fotografico," the following solution for staining paper for dark-room windows and lanterns:—

Tartrazine	96 grs.	10 gms.
Rhodamine	10 grs.	1 gm.
Water	10 ozs.	500 ccs.
Alcohol	10 ozs.	500 ccs.

This gives a good orange light, which is perfectly safe for very rapid plates, provided they are not unduly exposed to it.

Photo-Mechanical Notes.

Direct Three-colour Negatives on Dry Plates.

Dr. Loewenstamm and Herr Hoffert, of the Photo-chemical Laboratory of the Charlottenburg School, have been making a series of experiments in this direction, at the suggestion of Dr. Miethe, and point out that the troubles hitherto met with in the use of dry plates for direct half-tone negatives have been insufficient density in the dots and presence of fog. The following procedure is the result of their experiments:—Transparency plates are bathed with Miethe's ethyl-red. They must be backed with a black backing, which must naturally be in optical contact. To ensure accurate ratios of exposures, a scale of greys should be used; but better than this is, they state, to secure a correct ratio by obtaining identical size of dot in all three negatives. The three exposures should be made with the screen, and the three filters with a sheet of white paper as the subject. The exposure must be generous, or else sufficient density will not be obtained in the dots, and development should be arrested before any fog appears. The particular developing formulæ recommended are:—

Edinol	10 grammes.
Potassium carbonate (dry)	80 grammes.
„ metabisulphite	20 grammes.
„ bromide (10 per cent. sol.)	3 ccs.
Water	1,000 ccs.
Or—	
Edinol	10 grammes.
Sodium carbonate (cryst)	150 grammes.
Acetone sulphite	50 grammes.
Potass. bromide (10 per cent. sol.)	2 ccs.
Water	1,000 ccs.

Both developers keep well, and may be used more than once. Development will be complete in from three to four minutes and the lights should be dense and the shadows glass-clear. The negatives should be etched with Farmer's reducer till the dots in the half-tones begin to lose in density. They are then washed, the plate bleached with mercury, blackened with ammonia, again etched with Farmer's reducer, and the operations repeated until the dots are correct.

Removing Enamel from Etched Plates.

"Which is the best method of cleaning off the enamel from etched plates?" and "Is it necessary to clean it off at all?" A writer in "Process Work" deals with these two questions. In answer to No. 1, the most expedient and effectual way of removing the enamel is to place the plate into a dish of hot caustic potash or caustic soda when it will float off in a few minutes. Then brighten the plate in the usual way by using the chromic acid formulæ as before given in these columns. Now, as to Question No. 2. This is quite unnecessary in ordinary cases, as by retaining the enamel you not only gain additional printing depth, but the surface of the block is preserved as well. In the early stages of the enamel process, during the various stages of rough and fine etching, proving, etc., the quality of the enamel may be too weak to resist these actions on its surface, and consequently come off in patches, leaving the surface of the plate irregular. Therefore the only remedy will be to remove it altogether. But, of course, with the enamel now in use these difficulties have entirely disappeared. Here are a few exceptional cases, when it is advantageous to remove the enamel, viz., in cases of fine screen vignettéd work, so as to avoid a tendency to hard marking. Again, when burnishing is necessary or the surface of the enamel is scratched; but in ordinary cases the majority of printers prefer the enamel left on the plate.

A Hard Resist.

"What is the resistant used by cutlery firms for making up resistant varnish when etching names?" To a querist on this point, Mr. S. H. Horgan replies that gum guaiacum dissolved in alcohol to make a thin film on the steel is the solution employed. The name is printed with potash solution from a rubber stamp, which removes the varnish where required, and the blade is then etched in nitric acid. The potash, when applied with the rubber stamp, turns the gum into a soap, which dissolves in the nitric acid. But a very weak nitric acid bath is required to dull the polished surface of the exposed steel. The acid is usually applied with a sponge, instead of dipping the steel blade in a bath, and the reason for this is that, in coating the blade with varnish, it is almost impossible to cover the sharpened edge of the blade so perfectly that the acid will not penetrate and corrode the steel there.

Veiling of Enclosed Arc Glasses.

Talking of the trouble which is often found with the enclosed arc lamp, viz., the collection of a white powdery film on the glass and the subsequent burning of the film into the glass as an orange stain, the "Inland Printer" writes:—

"We are having the same difficulty on this side of the water. The orange discoloration only forms around the upper rim of the globe. When it begins to interfere with the actinic quality of the light the globe is thrown away. At present the interior of the globes are flowed with albumen after washing in the morning. They are dried with the upper rim down, so that the film of albumen will be thickest there. The object of this treatment is that the film of organic matter, that is, the albumen, will prevent the white powder becoming fused into the glass. The globes are put in nitric acid every morning, which loosens the film of hardened albumen, carrying with it the white powder deposit."

THE PROFESSIONAL PHOTOGRAPHERS' SOCIETY OF NEW YORK.

THE first meeting of this newly-formed body of New York photographers was held on April 13 last, Mr. Pirie MacDonald, President, in the chair. As the proceedings at that meeting will be perused with interest by many photographers on this side of the Atlantic we extract here from a lengthy report in the current issue of "The Photographer" (New York). The constitution and bye-laws of the society were unanimously adopted, and we need not refer to them at length. The membership of the society is to consist of.—(1) Active members, professional photographers, who are owners of and have establishments within the State of New York; (2) Associate members, professional photographers, not residents of the State of New York, who will be entitled to all the benefits and privileges of active members except that of voting; (3) honorary members shall be distinguished non-resident professional photographers whom the society desires to honour, or members of the society who by reason of their services to photography the society wishes to reward.

The subscription for active and associate members is to be 3 dols. (12s. 6d.) per annum.

Branch organisations, to be known as sections, composed of members of the society who may so elect, may be organised within the State of New York with the object of assisting and promoting the welfare of the society and handling questions of local interest. All expenses of such branch organisations must be borne by the sections themselves.

Reports from the Committees on Insurance and Copyright respectively were presented, and read as follows:—

Insurance.

The question of insurance on the premises and property of photographers is a matter of long-standing complaint on their part, at the manifestly unjust discrimination made against them in the item of a base rate. All lines of business have a base rate which may be increased by the conditions surrounding the individual risk—the building itself, or adjoining it; the base rate for photographers is 1.25, while that for the retail druggist is .75; the plumber and gas fitter, .75; the lithographer and printer (foot and hand power), 1.00; and paint and varnish stock is rated at 1.50.

All efforts that have been made in the past to induce the Rate Committee of the Board of Fire Underwriters to make an investigation into the condition under which our business is conducted, and adjust our rating on a basis more nearly approaching the conditions of the present day have met with no result, and your committee are convinced that the said Rate Committee have no proper knowledge of the technical conditions under which photographers to-day carry on their business.

An endeavour to find some record of losses by fire during any one year or term of years was unsuccessful. Such record, if any exist, must be found among the individual companies insuring photographers, and collated. It has been suggested in a talk with a former member of the Rate Committee that they may be gathered in the form of statements from the various photographers themselves of premiums paid over a term of years, and the losses (if any) collected.

As an organised body, it is probable that a committee of this society, appointed for that purpose, would be given a hearing before the Rate Committee and an opportunity to present their data and arguments asking for a reduction in what we consider an excessive rating.

In conclusion, we would recommend that a committee be appointed with power.

Copyright.

Your Advisory Committee on Copyright, appointed by the President at the preliminary meeting on February 5, after careful con-

sideration of the large and constantly growing use of photography by the magazines, newspapers, and other publications of this country, and realising the very inadequate protection given us by the present copyright laws, sees no ways of securing much relief from present conditions until a new and fairer copyright law shall have been passed.

By "present conditions" your committee refers to the fact that in the United States at the present time, hundreds of thousands of photographs are being continually reproduced by these publishers without any monetary consideration to the photographer.

Your committee believes that the time has come when the photographers of this country should refuse any longer to furnish grist free of charge to the mills of other publishers, allowing them to make all the profit our work may bring and being satisfied with an occasional credit line under the reproductions.

Your committee, therefore, recommends the adoption of similar rules to those which have been in vogue for the past ten years and which are still working so well in England, and which may broadly be summarised as follows:—

No. 1.—No member shall allow any of his copyright photographs to be reproduced by any newspaper or other publisher without receiving pay therefor.

No. 2.—All members shall agree that such pay shall never be less than an amount to be mutually settled upon.

No. 3.—Any member may at his pleasure charge more than such minimum rate, according to his own idea of the value of the picture in question, but never less.

No. 4.—Such charge shall be only for the reproduction right, and shall not include the print to be copied, which print shall be charged for in addition.

In the case of uncopyrighted pictures also, it is the unanimous opinion of the committee that the custom which has, to some extent, prevailed in the past of giving prints without pay to other publishers, is unwise, unnecessary, and undignified—that it should, therefore, be discontinued—and that no print, whether copyrighted or uncopyrighted, should be given out for publication unless paid for at regular rates.

Other Business.

An application from a body of New York City Photographers for permission to form a Metropolitan Section of the Society, as allowed for under the constitution, was put in and accepted.

Also an application for the formation of a Central Section of New York State was filed and accepted.

An application for a Western Section with Rochester as its centre was also filed, but not being in proper order was not acted upon at this session.

Mr. Core addressed words of congratulation to the President, Pirie MacDonald, for his splendid work, and then Mr. M. B. Parkinson, of Boston, addressed the members on the exhibition of pictures, and commended the action of the committee in its policy of selection as being a feature which beyond question required great bravery, but had proved itself to be the proper plan, winding up with a warm invitation to visit Boston in August for the National meeting.

Mr. Waide spoke on the greater fraternal condition that can be brought about by this new society, suggesting, in the words of Mr. Carnegie, that your competitors should be your best friends.

Mr. Waide moved that a committee be appointed to go into the matter of the adjustment of insurance rates. The motion was adopted.

Mr. MacDonald read an invitation from Mr. E. S. Curtis, of Seattle, Wash., to visit his exhibition of Indian pictures at the Waldorf-Astoria that afternoon.

Mr. Olivier spoke on the apprenticing of photographic assistants, stating how difficult it was to get competent help for the printing

and work-rooms. He offered a resolution to appoint a committee to look into the matter and report. The resolution was adopted, and the President appointed Mr. Olivier, Mr. Eddowes, and Mr. Core to serve on the committee.

THE OPTICAL CONVENTION.

THE preparations for the Optical Convention, which opens on May 30, are now approaching completion, and it is hoped next week to issue a full programme of the arrangements, including the list of papers and subjects for discussion.

In addition to the papers previously announced, a contribution is promised from Lord Rayleigh on "The Polishing of Glass Surfaces," and Professor Shuster will read a paper on "Spectroscopic Optics."

The demonstrations of special apparatus, arranged for the afternoons, include the following, viz.:-

Multiple Colour Illumination for Microscopic Objects, Mr. J. Rheinberg.

Diffraction Apparatus, Mr. J. Rheinberg.

Quartz Crystals, Mr. J. Woodward.

Spectroscopes, Mr. F. Twyman.

Interferometer, Mr. H. Stansfield.

Further applications for membership should be sent without delay to the hon. secretary, Mr. F. J. Selby, Elm Lodge, Teddington, Middlesex; the subscription for membership being five shillings. It is, perhaps, hardly necessary to add that lady members will be especially welcomed.

The catalogue is now in the printer's hands, and will shortly be ready for issue.

It is not confined to apparatus actually exhibited; the aim has been to produce as full an account as possible of the types of optical, meteorological, and other scientific instruments manufactured in this country, in a form which shall be as convenient as possible for purposes of reference. To this end the instruments have been carefully classified, and the table of contents will at once indicate where particulars of any special class of instruments are to be found. An alphabetical list of firms and exhibitors, with a general statement as to the instruments by each maker which are described in the catalogue, and a carefully-compiled index of instruments, are provided at the end of the volume. The general interest of the catalogue is greatly increased by the introduction to each of the various classes, in which a short account is given of the more important types of instruments included in the pages which follow. Each of these introductions has been written by an expert, and they add in no small degree to the attractiveness of the volume.

The aim of the Convention is one well worthy of the support of all those interested in scientific and technical development in this country; and all who are familiar with such optical instruments as the binocular, the photographic camera, the microscope, the projection lantern, etc., etc., will find much to interest them in the exhibition. Spectacles and eye-glasses are well represented; and this class includes a very complete collection of spectacles, from the oldest to the most recent forms, exhibited by Mr. W. W. Dunscomb, of Bristol. Acknowledgment is due to the help received from various guarantors and donors. Among recent contributions must be mentioned donations of £50 from the Mercers' Company and from the Goldsmiths' Company, and one of £10 from the Clothworkers' Company. Further promises of guarantees or donations should be sent to the hon. treasurer, Mr. E. B. Knobel, F.R.A.S., 32, Tavistock Square, W.C.

MR. THEODORE BROWN informs us that his private address, at which he transacts the editorial business of the "Optical Lantern and Cinematograph Chronicle," has been changed to Westcot, Drummond Road, Boscombe.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

The following applications for Patents were made between April 25 and 29:-

MOUNTING.—No. 8,873. Adhesive folding tablets for mounting photographs, etc., in albums and elsewhere, so as to be readily removable without damage, although securely attached. Thomas Smith Jacob, 1, Quarry Mount Terrace, Delph Lane, Woodhouse, Leeds.

DEVELOPMENT.—No. 8,911. Improvements in development of photographic plates and films. William Fraser Claughton Kelly and John Arthur Benthall, 7, Southampton Buildings, Chancery Lane, London.

DRAINING RACKS.—No. 8,964. Improved photographic draining rack. Houghtons Limited, and Herbert Holmes, 88, High Holborn, London.

TUBES FOR CHEMICALS.—No. 8,971. Improvements in tubular receptacles for small quantities of photographic chemicals. John J. Griffin and Sons, Limited, and Ephraim Thomas Pratt, 37, Essex Street, Strand, London.

COMPLETE SPECIFICATIONS ACCEPTED.

Specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

AUTOMATIC ENLARGING.—No. 12,734, 1904. An enlarging system, of design such that the various parts are automatically placed on one of them being adjusted for a certain degree of enlargement. The patentee bases his method on the formulae:-

$$\text{Back focus} = f + (f \times n)$$

and

$$\text{Front focus} = f + (f \div n)$$

where f is the focal length of the lens and n the degree of enlargement. It is seen that for every additional unit of enlargement the back focus increases by a fixed increment, and the

Fig. 1.

front focus diminishes by a constantly decreasing amount. The construction of the movement is based on one or other of two principles:—(1) If a lever be pivoted at one end of a given base, and inclined so as to form the hypotenuse of a right-angled triangle of which the remaining side is equal to the equivalent focus of the lens, it can be shown that the uniform movement of a point acting against the lever, along a line parallel to the base, will depress the lever so that it cuts the side of the triangle in a constantly diminishing ratio, and (2) a right-angled lever may be pivoted at one end of the base, so that the latter intersects the angle between the arms of the lever, then if one arm of the lever be inclined so as to form the hypotenuse of a right-angled triangle as before and the remaining side be made equal

to the equivalent focus of the lens, it can be shown that the uniform movement of a point acting on the other arm of the lever, along a line at right angles to the base, will cause the lever to move a constantly decreasing distance along the side of the triangle. In each case the distance travelled by the point for each unit of magnification should be to the distance of its path from the pivot of the lever as the length of the base is to the focus of the lens, or—

$$\frac{\text{Distance moved per unit magnification}}{\text{Distance of path from pivot of lever}} = \frac{\text{Cotangent of angle between lever and base in first position.}}$$

or in other words:—

$$\text{Length of lever} \times \cosine \text{ of its angle to axis of lens} = n \times f.$$

Fig. 1 explains method 1. B. C. is the focal length of a lens ; A. C. a pivoted lever forming the hypotenuse of the right-angled triangle A. B. C. : D. X. parallel to A. B. is divided at F. G. so that E. F. and F. G. each equals D. E. Now, depressing

Fig. 2.

A. C. to the position A. H., A. B. is bisected, with the lever at A. K., intersecting D. X. at a distance F. G. further on B. C. intersected at K. Thus, for equal distances moved by a point along D. X., the intersection of the lever A. C. with the line B. C. takes place at unequal decreasing distances along B. C. In other words, for a given constant movement of the lever A. C. along D. X., a diminishing displacement of the lever along B. C. takes place. Fig. 2 is the diagram of the second method. Here C A M is a right-angled lever. If the arm A M is moved through the equal distances E. F., F. G., the movement of the arm A. C. is through C. H., H. K. These methods are applied to the construction of an automatic enlarger in the following ways:—(1) A point is moved along the line D. X., by gearing or otherwise, in direct proportion to the movement of the lens carrier along the baseboard, so that a uniform movement of the lens carrier causes a varying movement of the lens carrier with the lever connecting the lens carrier with the negative carrier; and (2) a point E, fixed to the base of the

positive carrier is caused to act on the arm of the lever A M, so that when the distance of E on the positive carrier is varied from the pivot A of the lever, and the positive carrier is thereby altered, the other arm of the lever causes a varying motion of the lever A. C., connecting the lens carrier with the negative carrier. Figs. 3 and 4 show two forms of apparatus where the adjustment is controlled by the second method. In Fig. 3 the positive carrier *a* is fixed and the negative carrier *b* and lens carrier *c* are movable; the mechanism employed consists of two right-angled levers *h* respectively pivoted at *i* to the movable lens carrier *c*, the longer arm *h*¹ of each lever either being adapted to slide freely through a swivel eye at the point *j*, where it is connected to the positive carrier *a*, or arms *h*¹ may be slotted so as to be adapted to slide over a fixed pin or slot at *j*; while the other end *h*² of each lever is attached at the point *k* to, or otherwise arranged to act at the point *k* on the movable negative carrier *b*, such connection at *k* being effected by means of a stud engaging in a slot in the lever arms *h*², or the latter may pass through a

Fig. 3.

Fig. 4.

swivel eye—or other similar or equivalent devices may be employed. To adjust the apparatus the operator moves the carriers direct or pushes or pulls the end of the levers *h* in the direction of the double-ended arrows *x*, so that as the levers are forced past the joints *j j* of attachment or connection to the positive carrier *a*, consequently each rectangular lever is rocked on its pivot *i*, and thereby the outer end *h*² of each lever moves the negative carrier *b*, and the desired relative movement is thereby imparted to the lens carrier *c* and the negative carrier *b*—both relatively to one another and to the positive carrier. In Fig. 4 an arrangement of levers *h h* is shown, somewhat similar to Fig. 3, said levers being pivoted at *i* to the lens carrier *c*; but in this case the positive carrier *a* is made movable, and has the levers *h* attached or connected thereto at *j* in a manner similar to that described with reference to the point of attachment at *j* of the levers *h* in Fig. 3; while the other ends *h*² of the levers are similarly attached at *m* (as at *j*) to the base *z*, or the negative holder *b*, which latter

in this arrangement is fixed. The position of the points of attachment or connection of the levers to (*i.e.*, the points where same act on) the negative and positive carriers may be determined as follows:—The levers and negative and positive carriers are placed in the position they are intended to occupy, when the apparatus is at “unity.” Then lines drawn on the bases of the negative and positive carriers at right angles to the axis of the lens, at distances equal to the equivalent focus of the lens from the line through the pivots of the levers (*i.e.*, the points where same act on the carriers) will cut the centre of the slots in the levers at the required points. The positions of the vertical planes of the negative and positive carriers may be likewise determined by lines drawn at right angles to the axis of the lens at a distance from its optical centre equal to twice the length of the equivalent focus of the lens. Other figures show the attachment employed to provide for the use of lenses of different focal length on a given apparatus, but the diagrams are too complicated for reproduction. Henry Rex Cook, Major, Royal Garrison Artillery, Fort Fareham, Fareham.

RELIEF PHOTOGRAPHS.—No. 23,093, 1904. A method of obtaining prints in relief by printing an impression from a photographic negative on a sheet of sensitised porous unsized paper, stretching this impressed sheet in a frame, coating the back of the sheet with glue, applying over the glue a thin layer of plastic compound capable of becoming subsequently hard, and modelling the picture from the front against a board by means of modelling sticks. Friedrich Gärtner, 43, Tanusstrasse, Wiesbaden, Germany.

New Materials.

The Barnet “Red Seal” Plate. Manufactured by Elliott and Sons, Ltd., Barnet, Herts.

Messrs. Elliott have made several notable additions to the list of photographic manufactures within the past few months. Chief among them we should place the Barnet “Ortho” plate, an emulsion of remarkable general and colour-sensitive properties. The “Ortho,” it will be remembered, albeit of special character, is issued at the minimum price of 1s. per dozen quarter-plates. The same step is taken by Messrs. Elliott in introducing their new “Red Seal” plate, one of ordinary (not isochromatic) character, and already conspicuous in its highly decorative wrapping in the dealers’ windows. For the “Red Seal” Messrs. Elliott claim the following qualities, and from what we know of their managerial methods we believe they are difficultly persuaded to make one single claim which they cannot satisfy:—

- Remarkable speed;
- Abnormally high in density;
- Free from fog;
- Wonderful latitude in exposure;
- Ease and quickness of development.

A number of camera tests proves to us that we have in the “Red Seal,” an emulsion which responds in a remarkable manner to the demands which may legitimately be made upon a plate with a list of accomplishments such as the above. A series of brief hand-camera exposures made alongside a plate esteemed for its extreme rapidity showed the “Red Seal” well able to undertake the onerous tasks which the hand-camera worker can lay upon it; and in development by the pyro-soda formula of the makers good density and contrasts were quickly obtained. We need say less on this point because we have before us the results of sensitometric tests made for

us by Mr. C. E. Kenneth Mees. B.Sc., which corroborate practically every one of Messrs. Elliott’s claims. We quote the figures as obtained with pyro-soda, the inertia being taken at infinite development:—

Inertia (pyro-soda)	156
Watkins number (pyro-soda)	320
γ_{∞} (density giving power of the plate)	2.73
Opacity (to blue light, an index to the latitude of the plate)	22
K (velocity constant of development with standard ferrous oxalate)	146

These figures, taken with the camera exposures, satisfy us as to the excellence of the “Red Seal.” The combination of qualities recommends the plate for outdoor photography with hand and stand cameras, as well as for studio work, and the portrait photographer especially will be grateful for the quickness with which the plate develops to full density. It is, in short, a very excellent plate, and a triumph of scientifically directed manufacture.

“British” Ferrotypes Dry Plates. Sold by the Flashtype Co., Ltd., King’s Head Court, Beech Street, Barbican, London, E.C.

Ferrotypes operators will be glad to hear of this ready-prepared plate, by which practically the results of wet-collodion are obtained. The Flashtype Co.’s new introduction is a collodion plate, for which perfect keeping qualities are claimed. Regarding that claim, we cannot, of course, speak with authority, as the plates have been in our possession a few days only. Indeed, “tintype” is a branch of photography with which we cannot boast an intimate acquaintance, but we were, nevertheless, able to obtain several excellent ferrotypes on the samples sent us. The makers describe the plates as considerably more rapid than wet-collodion, and they put the exposures from three to twenty seconds, in the studio, presumably, although they do not say so, with a portrait lens at $f/4$. On outdoor portraits, we found one second at $f/5.6$ sufficient. The plates develop rapidly—in about thirty seconds—and are just as quickly fixed and finished off. They are sold in all sizes, from Victoria up to 14 by 10 inches, at prices which may be taken as based on quarter-plates at 3s. a dozen.

“Sculptotype”—a new form of photograph in solid relief. Invented and patented by the Sculptotype Co., Ltd., 31, Edgware Road, London, W.

A new specialty for the photographer’s show case or reception room, and one that compels attention. One, moreover, that can be produced by the photographer himself, and calls for a very limited amount of skill. One, further, which is susceptible of any degree of finish in crayon, water-colours, or oils, and so can be given whatever elaboration is desired. These qualities are the distinguishing features of a photograph in relief, now being introduced under the name of “Sculptotype.” In appearance the “Sculptotype” is a profile, or three-quarter portrait in bold and solid relief, cut out and mounted on velvet, silk, or plush. The effect, we are informed, is obtained by moulding the front of the picture, not by pressing outwards from the back, and the method is responsible for the retention of the details of the original photograph. In other respects, the reliefs present a handsome, we might say, massive appearance; and we cannot imagine one even in a window display failing to attract notice. In regard to the technical process by which they are made, no special negative is required, and there is absolutely nothing which can be called apparatus employed in the preparation of the reliefs. The finish, as we have said, may be what the photographer chooses, and we can best give an idea of the cost of “Sculptotype” by saying that the prices can vary to just about the same extent as those of enlargements. In other words, you can make your raw “Sculptotype,” so to speak, for the price of an untouched enlargement, and,

over and above this, you can pay for working up in crayons, oils, or water-colours. The "Sculptotype" seems just as amenable to these embellishments as a bromide print: a trade-enlarger could take the working-up in hand without any departure from his usual course. The specialty is quite new, and, for further particulars of it than we have given here, the Sculptotype Co., Ltd., should be addressed.

GEM-FLEXOID LIGHT FILTERS.—We have received a sample booklet of "Geka" Flexoid and Gelatoid Light Filters. We have already drawn attention to these useful accessories for the dark-room, but put up in this convenient form they make a useful book of reference, in which every other "page" is composed of a piece of Flexoid film, quarter-plate size. These booklets are, for trade circulation, free, but any private individual can obtain one for 1s.; or small sample cards of the seven colours of Series I. and II. will be sent, with full particulars, by the sole importers, Messrs. A. E. Staley and Co., 19, Thavies Inn, Holborn Circus, London, E.C., on receipt of a penny stamp.

A NEW printing paper is now placed on the market, under the name of "Agol," by Banks and Co., 14a, South Hill Park, London, N.W., the treatment of which, after exposure to light, consists simply in immersion in water, or, better, weak ammonia. "Agol" is evidently an iron-silver paper of the Kallitype class, but, as made in the present instance, gives prints of a very black tone. Our own experience of such processes leads us to prefer hypo as a fixing agent, even though it has to be afterwards removed, but it is claimed for "Agol" that the sensitising salts are highly soluble and that the last traces of silver are removed by ammonia. The paper is recommended for copying tracings as well as for printing from negatives, and, for the former purposes especially, it may prove of service. Its price is based on the shilling packet of twenty-four quarter-plate pieces.

THE GEM "SALON" PLATE.—In giving speed numbers of these plates last week, we pointed out a considerable discrepancy in the numbers of Mr. Mees and Mr. Watkins. That difference, we find, is due to certain misconceptions, the recognition of which diminishes, if it does not entirely remove, the discrepancy. In the first place, the Watkins Meter Co. write us to the effect that "we have made a test of these plates (the 'Salon'), and the result was Watkins 325, and we wrote to the Gem Co. giving this figure." This speed, it should be noted, is for pyro-soda development, and in verbally communicating it to us the Gem Company pointed out that on conversion into H. and D. pyro-metol numbers it would come out considerably above 320. Secondly, by a clerical error, the speed number by Mr. Mees with pyro-metol was described as the "Watkins" instead of the "H and D." This "H and D" number (as defined by Hunter and Driffield) is $\frac{34}{\text{inertia}} = \frac{34}{105}$ or 324 in the present instance. The Wat-

kins number Mr. Mees takes as $\frac{50}{\text{inertia}} = 477$, thus confirming by actual measurement the figure calculated by the Gem Company from the Watkins pyro-soda number. If we place these figures against one another it will serve to show once again the desirability of the adoption of some uniform standard for the speed of plates, although we must confess that such uniformity seems further off than ever.

"H and D" number	$\frac{34}{i}$ (pyro-metol)	324
"Watkins" number	$\frac{50}{i}$ (pyro-metol)	477
	(Determined by Mr. Mees.)	
Watkins number (pyro-soda)		325
	(Determined by Mr. Watkins.)	
"Watkins" number (pyro-metol)		over 400
	(Calculated from Watkins number by the Gem Company.)	

These results may be taken as fairly concordant, considering the

absence of fixed numerical ratios between the various speeds. Mr. Mees writes us that he chooses $\frac{50}{i}$ for the Watkins number, taking pyro-soda as the developer, because that appears to accord with the majority of the Watkins speed numbers, but he would be willing to adopt any other conventional ratio for the conversion of inertia into the Watkins number.

New Apparatus.

The No. 3 Folding Brownie Kodak. Made by Kodak, Limited, Clerkenwell Road, London, E.C.

The younger members of the great Kodak family—the Brownies—appear to be growing steadily larger, both in respect of size and numbers. We recently noticed the No. 2 Folding Brownie Kodak, which was an advance on any previous Brownie in point of size, and now comes the announcement that an even bigger camera of the same type is being put on the market.

The No. 3 F.B.K. is for roll-film pictures, $4\frac{1}{2}$ in. by $3\frac{1}{4}$ in., or quarter plate. It is of the well-known folding type, and can be regarded as at once portable and compact. It measures but $8\frac{1}{2}$ in. by 5 in. by $2\frac{3}{4}$ in., weighs only $26\frac{1}{2}$ oz., and should meet with the same measure of popularity that has been accorded to its smaller brothers. The camera is an efficient little instrument, and in our hands has given negatives that compare favourably with those of other quarter-plate cameras. The lens, which has extremely good defining power, is a single one, and the shutter—actuated by a single-trigger release—gives time, bulb, and instantaneous exposures. A special feature is the automatic focussing device, which enables the lens to be set at 6, 8, 10, 15, 25, or 100 feet with an ease and certainty that is an advance on many focussing scales. The camera front can be automatically locked at any of the given distances, and remains perfectly rigid. A reversible finder and two screw sockets for use of camera on stand are provided, and the entire camera is well and strongly made of covered wood, with nickel-plated fittings. Its price is 37s. 6d., and a reliable quarter-plate roll-film camera should have a good sale at this figure.

DEATH OF MR. F. H. GANDY.—Many members of the Photographic Convention of the United Kingdom will regret to learn of the death of Mr. Frederick Hughes Gandy, of Derby, a gentleman who with his wife (an ardent amateur photographer) was for many years a constant attendant at these annual gatherings. Mr. Gandy had been ailing for some months, and, after much suffering, died at his residence on Saturday last, at the age of 48.

New Books.

"*Trite Élémentaire de Photographie.*" By G. H. Niewenglowski. Paris: Garnier Frères. 3 francs

If anybody wants to write another beginners' guide to photography—and there are at least half-a-dozen persons who are liable to do so without provocation—they need not be ashamed of taking a few hints from the subject matter of this French work and the way it is arranged. Probably the author meant to give more than a little over one-third of his space to printing processes, and we blame him for disregarding enlargement, but for the rest is a plainly written and comprehensive manual, so closely in touch with present-day photography as to give prominent places to roll-films and orthochromatics. And it has a word or two for the Watkins system of time development, naming the multiplier or constant the "coefficient arithmétique du révélateur." We fear "arithmetical coefficient" is too long for Mr. Watkins.

DR. STOLZE'S "*Photographischer Notiz-Kalender*" for 1905, published by Wilhelm Knapp, Halle a/S, at 1s. 6d., should be found useful to German readers. It contains a mass of useful tables and formulæ for the various processes, and a list of German photographic societies, and also a useful and fairly complete list of dealers and manufacturers which are classified, not only in alphabetical order of the towns, but also under the particular articles and materials.

LIBERAL illustration of the attractions of four health resorts—Broadstairs, Southport, Aberystwith, and Bournemouth—is carried out in the series of booklets issued by the town clerks of these places. A postcard will bring any one of the guides, for such they are, and prospective holiday-makers may be glad to take this means of obtaining a graphic account of these popular resorts. The publications are prepared by the Health Resorts Development Association, 2, Gray's Inn Road, London, E.C.

SHAM PHOTOGRAPHERS.—Exactly a year ago, a few days before Chester races, two well-dressed men with a camera visited the neighbourhood. Stopping at respectable looking houses, without consulting the residents, they placed the camera in front of the house and proceeded as if they were about to take a photograph. Their object, they said, was to make a collection of pictures to illustrate the different styles of architecture. "Of course," they added, "gentlemen and ladies could be supplied with copies, but they would have to be paid for in advance." In some cases this was done, and printed receipts were given, but the copies were never delivered. Possibly, observes the "*Chester Chronicle*," the same two gentlemen may try to repeat the fraud in some of the surrounding villages while visiting the races this week.

STILL THEY COME.—It is circumstantially reported, says the "*Star*," that a Parisian artist has not only succeeded in solving the problem of colour photography, but has actually placed his invention on the market in a very literal sense. It is stated that, having found himself able to reproduce in facsimile any particular picture he desired, he at once produced a few copies of valuable paintings and sold them to dealers as originals—so perfect was the imitation.

THE price list of J. Lizars, 101 and 107, Buchanan Street, Glasgow, includes, in its 200 pages, a whole host of photographic requisites; but, for one item alone, is worth the penny stamp, on receipt of which it is sent to any applicant. The outstanding section is that describing in detail, the "*Challenge de Luxe*" camera, and showing the work of which an instrument with a wide range of movements is capable. As in previous years, Lizars' list devotes some twenty-five pages to hints and formulæ.

Dews and Notes.

OPTICAL Trade at Rochester, N.Y.—Articles of incorporation have been filed in Albany by the Bausch, Lomb, Saegmuller Company, manufacturing engineering, astronomical, physical, and other instruments of precision. The Bausch and Lomb Optical Company is to be the sales agent of the new corporation, whose manufacturing plant is to be in the north end of the recently completed large addition to the Bausch and Lomb factory. George N. Saegmuller, of Washington, D. C., reports the "*Rochester Democrat and Chronicle*," has been well and favourably known since 1890, when he succeeded Fauth and Company, old-established makers of engineering and astronomical instruments. Many observatories in this country and abroad have been equipped by Mr. Saegmuller. The Chamberlin Observatory in Denver possesses in the large equatorial of twenty inches aperture one of the finest instruments in the country. Find circles now universally used were devised by him for this instrument and first used, together with many other improvements since adopted by all other makers. The twelve-inch equatorial in Georgetown College, Washington, built by Mr. Saegmuller, was the first instrument ever made to record all observations photographically, while the photographic transit of nine-inch aperture and the zenith telescope of six-inch aperture are perhaps the first instruments made in this particular line. He has also erected equatorials of twelve-inch aperture at Valkenburg, Holland; the new Naval Observatory, Washington; the Observatory of Brown University, Providence; the Catholic University, of America, Washington; Boston University, and many smaller universities. The largest telescope made by Mr. Saegmuller was one of twenty-four-inch aperture, which went to Manila, Philippine Islands. It had just been erected when Dewey destroyed the Spanish fleet. Several balls went through the dome, but fortunately missed the instrument itself. One of the specialties of the firm was the production of accurate graduations. The two automatic dividing engines which are just being erected in the fireproof vault at the new Bausch and Lomb building and to which soon a third will be added—are among the most accurate ever constructed. This is evidenced by the Cincinnati meridian circle which was put in fifteen years ago, and of which Dr. Porter, the director, says that its accuracy is so great that graduation errors are not being taken into account. The large circles at the new Naval Observatory and at Princeton have the same reputation. As the circles which are used on engineering instruments are graduated on the same engines, it is not to be wondered at that the engineering instruments made by Saegmuller have long been known as among the very best. To the engineering world Mr. Saegmuller is perhaps best known as the inventor of the solar attachment bearing his name. By means of this small instrument, which can be attached to any transit, the astronomical meridian can be determined by a single observation with all the accuracy required for accurate land surveys. This little solar is in use in all parts of this country, Canada, and Mexico. It does away with the unreliable compass needle. A new branch was added to the business by the upbuilding of the navy. Before the Spanish war, Admiral (then Captain) Sampson was the chief of the Bureau of Ordnance of the Navy Department. Admiral Sampson was the first to recognise the fact that the old open sights had to be abandoned and telescopic sights substituted. He intrusted the problem to Mr. Saegmuller, who has since then step by step improved the telescopic sights. The new firm will be kept busy for a long time making the sights for the navy. In order to shoot well the distance of the object to be hit must be known. This calls for an instrument which measures this distance, called the range finder. One called the nautical range finder has been perfected which gives admirable results by using

the depression of the horizon. It is used at a great height from the water in the military top. As it is not always convenient to mount so great a height, a new instrument is being built, which can be used anywhere, and will be first used during the annual target practice next September. Apparently, Rochester, already a centre for the production and distribution of optical and photo goods, is to become a centre for the production and distribution of scientific instruments and apparatus of all kinds, for the first work of the new firm is expected to be the nucleus of a far wider range of products. The work of transferring the plant from Washington to Rochester has been begun. Already five carloads of machinery and instruments have been unloaded and are being placed in the new building. Mr. Saegmuller has brought with him a number of skilled men, and skilled labour will be in demand. Associated with Mr. Saegmuller, who will continue as heretofore in active charge, are his sons, John L. and Fred. The latter is in Europe gathering facts relative to the latest developments in scientific instruments. It is the intention to establish a scientific bureau for computation and research on the lines of the celebrated Carl Zeiss works of Jena, the results to be available to both the Bausch and Lomb Optical Company and the Bausch, Lomb, Saegmuller Company.

ROYAL INSTITUTION.—A general monthly meeting of the members of the Royal Institution was held on Monday afternoon. It was announced that his Grace the Duke of Northumberland (President) had nominated the following Vice-presidents for the ensuing year:—Sir William de W. Abney, K.C.B., Mr. Shelford Bidwell, The Right Hon. Lord Alverstone, G.C.M.G., Dr. Ludwig Mond, The Right Hon. the Earl of Rosse, K.P., Sir Thomas H. Sanderson, G.C.B., Sir James Crichton-Browne (Treasurer), and Sir William Crookes (Honorary Secretary). The Right Hon. Lord Rayleigh, O.M., F.R.S., was elected Honorary Professor of Natural Philosophy, and Professor J. J. Thomson, F.R.S., was elected Professor of Natural Philosophy.

A WOOD-SPIRIT Incandescent Light.—Those interested in a self-contained light for projection and enlarging should note the verdict of the "Scientific American" on a lamp of Continental origin, very similar to articles which are already on the photographic market. It is as compact and light as an ordinary kerosene lamp and more easily operated, and has for a fuel supply wood alcohol. The burner, as compact as the usual kerosene burner, and adapted to fit any regular mount, is of a novel regenerative type, to which the wood alcohol is conducted by a wick. The latter needs no trimming, as the alcohol is gasified by the heat, and then being mixed with air, produces an intense flameless heat above, which renders brilliantly incandescent the usual netted Welsbach mantle, suspended from above and enclosed in a cylindrical slender glass chimney. This gives in very small compass an intense illumination, equal to forty-five candle-power with the small mantle, and a smokeless light of remarkable steadiness and brilliancy, and which can be perfectly regulated, with the advantage of being odourless even when lowered to bare incandescence. One of the points of novelty is an automatic device for feeding a minute quantity of alcohol from the fount to the burner in starting, which is done much in the same way as the usual mechanical extinguishing devices are operated on kerosene lamps. The small amount of alcohol thus brought up is simply ignited by a match, as in an ordinary lamp. In about a minute the light burns brilliantly.

DEATH from Cyanide.—Arthur Newman Smith, 35, of York, died at Castleford recently under singular circumstances. As an amateur photographer, he developed plates, using cyanide of potassium. Having a cut finger, blood-poisoning is supposed to have been set up. He had the attention of several specialists, but without avail.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

May.	Name of Society.	Subject.
12 and 13	West London Photo. Society ..	Annual Exhibition.
15	Southampton Camera Club	Messrs. R. & J. Beck's Cameras and Lenses. Demonstrated. Mr. W. F. Slater, F.R.P.S.
15	South London Photo. Society..	Platinum Paper. Messrs. Kodak, Ltd.
15	Wallasey Amateur Ph. Soc.....	Members' Evening.
15	Exeter Camera Club	Stereoscopic Photography. Mr. J. W. Huggins
16	Royal Photographic Society ..	Marine Photography, and Opening of "One-Man" Exhibition. By Mr. F. J. Mortimer.
16	Birmingham Photo. Society ..	Sale by Auction of Various Photographic Sandries.
16	Manchester Amateur Ph. Soc.	Gaslight Papers. Mr. J. D. Barwick.
17	Everton Camera Club	Messrs. R. & J. Beck's Novelties. Demonstrated. Mr. W. F. Slater.
18	London and Prov. Photo. Assn.	Morocco. Mr. John H. Avery.
18	Watford Camera Club	Apparatus Night.

ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held May 9, Major-General Waterhouse in the chair.—Mr. E. P. Butler read a paper on "Three-Colour Photography, with Examples." He explained the construction of, and exhibited, the camera employed by himself for obtaining the three negatives at one exposure. Two transparent mirrors were placed at an angle of 45 deg. to the axis of the lens. The image reflected from the first, after passing through a green screen, gave the green-sensation negative; that reflected from the second, the blue-sensation; whilst the direct rays formed the red-sensation image. The lecturer stated that his best results were obtained when the exposure was about five or six minutes. In preparing positives by the staining method for projection he preferred to stain the gelatine films beforehand. After sensitising and printing, it was found practicable to control development by inspection, although it was necessary in some cases to re-dye the films and wash out again up to the correct point. A number of three-colour transparencies were projected in demonstration of the author's practice. A number of these obtained and merited commendation, although the series included others of glaringly false colour-rendering, the general defect being too vivid colouring. The author was not optimistic as to the likelihood of three-colour work becoming popular. His total of exposures last year was stated as 147, of which he considered 44 satisfactory, a return of practically one plate in three.

BRECHIN PHOTOGRAPHIC ASSOCIATION.—The pressing need of rooms which has been worrying the Council of the Photographic Association for some time has at last been satisfactorily solved by the lease of those premises at 14, St. Mary Street, formerly occupied by the Association. They comprise a comfortable meeting-room, with suitable dark-room accommodation, and will be a great help in carrying on the work of this flourishing and enthusiastic Society. The question of funds for the suitable furnishing and decorating of the rooms is likely to be taken up in a hearty manner by the members.

LONDON AND PROVINCIAL.—Meeting held May 4, Mr. Furley Lewis in the chair. Mr. W. T. Wilkinson exhibited several negatives made from line originals on the Gem photo-mechanical plate. He spoke very highly of the performance of the plate in photo-mechanical work; its rapidity was 90 H. and D., and hence exposure could be cut down to an eighth or a tenth of that required by some process plates. Mr. T. E. Freshwater read a paper on the "Photochromoscope." He described the projection photochromoscope of Ives, in which the light from a half condenser, giving a parallel beam, is reflected right and left by transparent

mirrors, the direct pencil passing through the green screen, whilst those on the right and left respectively pass through the blue and red screens. The three projection lenses are so adjusted that the three axial rays converge to one point on the screen when a lever system of movement is closed, but diverge when it is opened. As regards making the negatives for chromoscope slides, Mr. Freshwater said that the colour filters had to be adjusted according to the light in which the work was done. The greater luminosity of bright light called for adjustment of the filters, and differences had to be made when changing from bright to dull light. Mr. Freshwater used Lumière's "Panchromatic" plate throughout, and he gave exposures in a ratio of, say:—Blue, 1; green, 6 to 7; red, 10. As a test of the correctness of the ratio, he took the density in each negative, of a neutral background, which should be identical in all three exposures. Considerable care was needed in treating subjects such as flowers, etc., for the position might easily alter during the long exposures which were often necessary. Turning to projection, Mr. Freshwater demonstrated the use of the lantern. The projection screens had to be suited to the illuminant. For arc light they were deeper than for the mixed jet. Reference was made to Dr. Miethe's projection apparatus, as recently exhibited in London, and Mr. Freshwater thought it suffered from incompetent handling. The employment of three lanterns, he continued, was not new. About 1897 Mr. Ives showed such a system in London, and in 1899 Messrs. Newton and Co. made one for a Urania in Budapest, the results of which are believed to have been satisfactory. The triple-light had been advocated by Sir Wm. Abney as the most perfect system of colour projection. Some discussion followed, in which Messrs. W. R. Stretton, J. S. Teape, Rapson, and the Chairman joined.

CROYDON CAMERA CLUB.—May 3.—Mr. A. E. Isaac gave a practical address on orthochromatic work. A number of commercial and home-made light filters were tested by means of a lime-light spectrum projected on to a screen, and it was interesting to note how, in several cases, certain of the filters, although lengthening the exposure less than others, were from the orthochromatic point of view distinctly superior. Except in those instances where a deep filter had been used, little difference was observable. In the discussion which followed, a somewhat novel point was raised. A member complained—and his experience is probably shared by others—that when using ortho plates, and a filter of known stopping power, he had found, for some unaccountable reason, the requisite exposure could not be gauged so accurately as when filters were not brought into requisition. He did not think that the known variation of the stopping power of the filters, under varying conditions of light, could account for the difference observable. Mr. C. E. Kenneth Mees said he had investigated the matter. The state of things indicated certainly existed, and the explanation was simple. A plate might have a wide general period of correct exposure, but it by no means followed that this latitude extended throughout the spectrum; indeed, the reverse was the case, and almost without exception the latitude of a plate was very slight indeed in the yellow. The insertion of a filter would therefore alter the gradation, and the limits of permissible errors in exposure would be seriously reduced.

WORCESTER CAMERA CLUB.—A meeting of the Worcestershire Camera Club and Photographic Society was held at the Victoria Institute, on Wednesday evening last, when there was an attractive exhibition of members' lantern slides. During the evening the Rev. Johnson Barker judged the slides sent in for the annual competition, and with the following result:—Mr. T. B. Judson, 1, 36 marks; Mr. W. W. Harris, 2, 34; Mr. S. Hill, 3, 27.

RUGBY PHOTOGRAPHIC SOCIETY.—During the last few days of last week the Rugby Photographic Society is holding its annual exhibition at the Town Hall. The large loan collection includes enlargements from

snapshots taken by H.M. the Queen. Mr. B. B. Dickinson and Miss E. Sidebotham judged the members' exhibits, and the results were as follows:—Landscape: Medal, G. A. Towers; highly commended, F. Betts; commended, C. H. Ham and E. H. Hall. Architecture: Medal, C. H. Ham; highly commended, A. G. Evans. Snapshots: Medal, F. Betts; highly commended, G. A. Towers. Records: Medal, R. H. Myers; highly commended, E. H. Hall. Lantern slides: Medal, H. P. Harwood; highly commended, G. A. Towers. Wild life: highly commended, G. A. Towers. Enlargement: Medal, G. A. Towers; highly commended, F. Betts.

EDINBURGH PHOTOGRAPHIC SOCIETY.—At the last meeting of this society Mr. A. P. Noble read a paper on pin-hole photography. Photographs taken in this way, he said, gave a softer picture than those taken by the ordinary process, by means of a lens, and it was specially useful in photographing architecture, flowers, pictures, etc. A wide angle and narrow angle could be got with the same needle-hole, and focussing was not necessary.

INDUSTRIAL ALCOHOL.—Two questions on the subject of alcohol for industrial purposes were put in the House of Commons last week to the Chancellor of the Exchequer by Mr. Joseph Nolan, the member for South Louth, one of the most interesting facts elicited (reports the "Pharmaceutical Journal") being that the Government Bill to give effect to the recommendations of the Committee on Industrial Alcohol is now being prepared, and will be introduced as soon as it is ready. A point on which Mr. Nolan was particularly interested was the preparation from potatoes of crude alcohol for motoring and manufacturing purposes. In one of his questions he pointed out that millions of tons of potatoes are annually used in Germany in the way indicated. He asked whether, seeing that Ireland is a potato-growing country, the restrictions on the making of spirit there for industrial purposes could not be relaxed in such a way as to place Ireland in a position to compete with Germany and other foreign countries. The Chancellor of the Exchequer pointed out, in reply, that the Industrial Alcohol Committee, in their report, stated that they were satisfied that in the present agricultural conditions of this country it would not be possible to found a profitable industry on the employment of potatoes as material for distillation. The industry could not be carried on profitably unless the potatoes could be purchased at a price not exceeding £1 a ton, and in Ireland the price was not less than £2 a ton. The second question of Mr. Nolan brought forth the intimation that it is not intended to make proposals to give preferential treatment to the importation of West Indian patent-still spirit into the United Kingdom for industrial purposes. The Chancellor of the Exchequer added, however, that if the proposals of the Industrial Alcohol Committee are adopted by Parliament, spirit from the West Indies will derive a substantial benefit from the new arrangements, in common with all other spirit, whether imported or home-made.

BICHROMATE POISONING.—Last week, in the Hammersmith Coroner's Court, Mr. C. L. Drew held an inquiry with reference to the death of Henry George Johnson. Whilst at work on Good Friday the foreman told the deceased man that he might have some beer which had been placed in a gin bottle in a cupboard. After drinking some the man remarked, "What has been in that bottle?" and it was found that he had drunk a quantity of bichromate of potash which the french polisher had placed on another shelf in the same cupboard for safety. It was in a similarly shaped bottle. Thomas Vine, a french polisher, said he bought a pennyworth of bichromate of potash, and mixed it with water to use in his work. There were no restrictions on its sale; he could buy it at any oil shop. During the twenty years he had been engaged in the work he had never had a "poison" label on the bottle, but he should be more particular in future. Dr. W. R. Hall Harris said death was undoubtedly due to an irritant poison. The jury returned a verdict of "Death from misadventure."

CINEMATOGRAPHS OF WATER POLO.

To the Editors.

Gentlemen,—The secretary of our local water polo team has asked me to find out if any firm of cinematographers would be likely to entertain the idea of taking a match, a good one, say, London Polytechnic, London Amateurs, Nautilus, or some other first quality team, in our own waters. The three first-mentioned we have fixtures with this season, and have always won from them here, as our team always play in the open sea—I believe the only first-class team that does so—thereby affording a unique opportunity of getting a first-class film of a first-class match. Every facility would be rendered, such as providing staging where required, etc., etc. Can you please give me any names of firms likely to do it? Any hints you can give will be much appreciated.—Yours faithfully,

CINEMATOGRAFHER.

Teignmouth, May 8, 1905.

[Our correspondent should address one or two of the leading firms, such as Gaumont and Co., Cecil Court, London, W.C., etc. We shall be agreeable to placing any firm desirous of taking the matter up into communication with our correspondent.—Eds. B.J.P.]

THE DUBLIN MEETING OF THE PHOTOGRAPHIC CONVENTION.

To the Editors.

Gentlemen,—I shall be glad if you will kindly allow me, through your columns, to announce that both the London and North-Western and Midland Railways will run cheap excursions to Dublin from London, and nearly all the provincial and country stations on their systems, on Thursday evening, July 6. Tickets (available for return within sixteen days) from London (Euston) 26s., St. Pancras 22s. Return tickets from other stations 8s. 6d. to 26s., according to distance. For the advantage of those members who are able to remain after the close of the Convention, the various railway companies in Ireland have arranged to issue return tickets at single fares to any stations on their respective lines. Thanking you in anticipation.—I remain, Gentlemen, yours truly,

F. A. BRIDGE, Hon. Sec. and Treas.

East Lodge, Dalston Lane, London, N.E.

OSMOTIC PRESSURE.

To the Editors.

Gentlemen,—I am sure that your readers will extend a very hearty welcome to the series of papers by Mr. Mees, begun in your last issue, and dealing with the application of modern developments of general physical chemistry to the chemistry of photography.

But I fancy that Mr. Mees' explanation of the generation of hydrostatic pressure in a tube with semi-permeable base must have perplexed rather than enlightened many readers. Has a satisfactory explanation ever yet been given of the mechanism whereby a hydrostatic pressure is generated in an osmotic cell? I believe not. Modern investigations on solution have been conducted with a view to answering the question "how much?" rather than the question "why?"

Professor Ostwald, in his classical "Chemie," does not attempt any

mechanical explanation of the osmotic generation of pressure. In his "Theoretical Chemistry," Professor Nernst, it is true, does venture an explanation; but I fancy that to the average person this explanation will be somewhat reminiscent of the case of the gentleman who tried to lift himself by tugging at his own boot-straps. Here is Nernst's account of the matter:—"As a result there follows the pressure action on the semi-permeable membrane, as above described; but the membrane cannot yield since it is fastened to the resistant porous cell; therefore, according to the principle of action and reaction, there will be exerted on the solution an impulse which will tend to drive it away from the membrane. This impulse will cause the solution to rise in the upright tube from the simultaneous influx of water."

It is well known that a gas at low pressure will flow into a semi-permeable enclosure occupied by another gas at higher pressure and itself incapable of passing through its enclosure. But it is not the higher pressure of the gas inside the enclosure that causes the flow of the other gas into the enclosure. The cause of the flow is rather to be sought in the tendency, which every gas shows, to assume the same concentration—i.e., to distribute the same number of its molecules per cubic centimetre—throughout the region to which it has access. Dilute solutions would seem to behave as gases in this respect.

If we assume that the dissolved body in the osmotic cell combines in some loose manner with a certain number of the molecules of its solvent, then the concentration of pure solvent inside the cell falls below that of the pure solvent outside the cell, and hence solvent flows into the cell in the effort to establish the condition of equal concentration referred to above. From this point of view the flow of water would seem to occur, not because of what has been called osmotic pressure, but in spite of it.

Though the gaseous phenomena I have referred to give some sort of analogic precedent for the passage of solvent into an osmometer against hydrostatic pressure, yet the analogy is far from complete and must not be taken too far. The analogy must be looked on as a temporary and partial mental reconciliation to the peculiar behaviour of the osmotic cell, but as nothing more.

Mr. Whettam, in his book, "The Recent Development of Physical Science," writes with authority and pertinently in this connection:—"The proof involves no assumption as to the physical mechanism by which the osmotic pressure is produced. . . . The physical *modus operandi* of the pressure remains uncertain."

Blackheath, S.E.

D. J. CARNEGIE.

AMATEUR AND PROFESSIONAL.

To the Editors.

Gentlemen,—In a recent edition of your paper there is a note *re the above*.

Will you say if a lady, not a photographer, who attends public athletic meetings, and such-like gatherings, all over the country, sends copies to the various sporting papers, receives fees; also takes a quantity of local views, sells the right to reproduce as postcards to local stationers, who then publish large quantities—is such a lady entitled to enter these same views in an "amateur class" in a local photographic exhibition, and so compete with the usual schoolgirls, boys, and others for the prizes?—I am, yours, obediently,

N. LEWIS.

Russell Square, W.C., May 3, 1905.

[We may define a professional photographer as a person who makes the production of photographs his chief means of livelihood, and our correspondent's lady friend would almost seem to come within that definition.—Eds., B.J.P.]

THE R.P.S. ONE-MAN EXHIBITION.

To the Editors.

Gentlemen,—I am happy to inform you that Mr. F. J. Mortimer has sufficiently recovered from his recent illness to open his One-man Exhibition of Marine Photography on the 16th inst., at eight o'clock, p.m. The exhibition will be held at the Society's house, at 66, Russell Square, and will remain open for several weeks. Visitors will be admitted from 10 a.m. till 6 p.m. on presentation of visiting cards.—Yours faithfully, J. McINTOSH, Secretary.

MAKERS' FORMULÆ.

To the Editors.

Gentlemen,—Mr. Tennant is quite wrong in assuming that I believe "that the ounce measure of water contains 480 grains by weight." I contend that the original A formula cannot be a 10 per cent. solution according to photographic custom, because if the avoirdupois ounce of 437.5 grains be used, and the total bulk of solution be made up to 10 fluid ounces, any operator measuring out, let us say, 30 minims to obtain 3 grains of pyro, would not have 3 grains of pyro, but just under $2\frac{3}{4}$ grains, and this is not what the photographer wants. He does not want to develop a plate with an ounce of pyro, but with a few grains, so that it is incongruous to talk of the A solution giving us an ounce in 10 oz., or a gramme for 10 ccs., because the majority of photographers do not use metric measures.

I was perfectly well aware of the Order in Council as to barometric pressures, but my query was "wrote sarcastic," and I meant to hint that if we were to use the millilitre instead of the cubic centimetre, every photographer would have to correct for barometric pressure when measuring out 10 ccs. to obtain absolutely correct results.

The whole trouble lies in the fact that we photographers do not weigh, but measure, our solutions, and the avoirdupois ounce does not bear a definite ratio to the liquid ounce when measured.—Yours faithfully, CHEMIST.

Edinburgh.

PLATE MEASUREMENTS.

To the Editors.

Gentlemen,—I am very pleased to note that in your account of the "Salon" plate you have given the measurements of the constants of the plate, made according to the system of Mees and Sheppard, and I hope you may follow the same course in the case of any other new plates you may notice.

I think there is a small printer's error; should not γa be $\gamma \infty$ (gamma infinity)?

In future measurements it would be a help if the temperature at which development took place were stated, and also if the constants obtained by a pyro-soda developer, similar to the Hurter and Driffield standard developer, were given.—Yours faithfully,

W. B. FERGUSON.

Arosa, Switzerland.

May 6, 1905.

[We are glad to have Mr. Ferguson's notification of an error which did not escape us as the issue was prepared, but which we regret should have found its way to the press.—Eds., B.J.P.]

FREE Lessons in Liverpool.—We hear that a course of instruction from which beginners are greatly profiting is now being given by the Liverpool staff of Mr. J. Lizars. The preliminary lessons are free, and a charge of 5s. is made for the more advanced series. Particulars are obtainable from 71, Bold Street, Liverpool.

Answers to Correspondents.

* * All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C. Inattention to this ensures delay.

* * Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

* * Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington Street, Strand, London, W.C.

* * For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED :—

H. J. Sheppy, Rensburg, 47, Crescent Gardens, Bath. *Photograph of a Fringed Marchal Niel Rose*
R. Wilkinson, The Studio, Horncastle, Yorkshire. *Photograph of the Primitive Methodist Chapel, Horncastle*
E. Higgins, 18, Bury Road, Birkdale, Southport. *Photograph, a Row of Cottages known as Diamond Row, which stood in Stockport Road, Gee Cross, in the Borough of Hyde, Cheshire, but which were taken down about two and a-half years ago for Tramway Purposes.*

F. Kirkman, 34, Top-o'-th'-Wood, Heywood, Lancashire. *Photograph (post-card) of The Old Smithy, Little Lever, near Bolton, Lancashire (now demolished).*

CANADA BALSAM.—Some Canada balsam, which was stiff but fluid when bought, has become so stiff that I have to dig it out of the bottle. Should this be so, and how can it be thinned? I find it does not flow, even when warmed.—C. MARSHALL.

Add a little turpentine and stand in a warm place.

STAINED P.O.P. POSTCARDS.—Can you account for stains on enclosed postcard? A batch of prints toned previously in same bath showed no signs of stain.—F. P. W. B.

The stains appear to be due to contamination of the toning bath, probably with hypo. See that all dishes are perfectly clean before toning, and use a fresh toning bath for each batch.

DEVELOPER FOR FILMS, ETC.—1. Which is the most suitable developer for snapshot work on films. I unfortunately cannot use metol? I am using pyro-soda with bromide. 2. Could you suggest a safe-hardening solution for glossy postcards, one which would not retard toning? Alum is no good; I have not tried formaline, but the manufacturers recommend it before first washing. It is to prevent the postcards breaking at the edges, and so creating for my spotters a great deal of work. 3. Enclosed is a film, is the fogging due to too short exposure? The light was pretty good, and the exposure 1-25th second at f/8.—BOWLER.

1. We see no reason why you should not obtain good results with pyro-soda. Try the following formula:—A. Pyro, 1 oz.; potass. metabisulphite, 1 oz.; water to 9 oz. B. Soda carbonate (dry), 570 gr.; potass. metabisulphite, 220 gr.; water to 10 oz. C. Potass. bromide, 10 per cent. solution. Start development with A. 20 minims, B. 120 minims, C. 5 minims; water to 2 oz. After details have appeared, add 20 minims more of A. Both ortol and adurol are good developers for films. Use the maker's formula. 2. It should be quite possible to use formaline. Why not add some to the fixing bath, say 1 oz. to the pint. The probable cause of the gelatine softening is because you use a sulphocyanide toning bath. Try the following:—Soda phosphate, 60 gr.; water,

40 oz.; chloride of gold, 2 gr. This is sufficient for about 30 postcards. It is ready for use one hour after mixing, but does not keep long. 3. The fogging appears to be due to forcing in the development. The negative is very under-exposed and out of focus. The camera also appears to have moved during exposure.

REMOVING FILMS.—Will you please inform me how to remove film from lantern plates? I intend them to be used as cover glasses.—J. B.

Soak your plates in spirits of salt diluted with, say, five times its volume of water. After an hour in this mixture the film can be rubbed off easily with an old nail brush. Another plan, and one which we prefer for its cleanliness, is to soak the plates for a few minutes in a strong solution of chrome alum. The gelatine can then be peeled off in one piece without tearing, and leaves the glass perfectly clean.

P. W. H. (Birmingham).—Certainly, we have used plates in the camera with complete success. The instrument is a very convenient one.

COPYING.—I have a cabinet I want to copy for enlargement: I have an Optimus R.R. lens, half-plate, 8 in. focus. The extension of my half-plate camera is about 14 in. Can you kindly tell me the best method of completing the above task, and what plates to use?—W. G. PAYNE.

As it is not possible to copy the original the same size with the lens and camera extension you give, do not attempt it, but make your copy about quarter-plate size on the half plate. Use an ordinary or slow plate, and if the original is at all faded, use a photo-mechanical plate and a blue screen. Give a full exposure, and develop with hydroquinone or glycin. Make the copy negative as sharp as possible, and there ought not to be any difficulty in enlarging from this to any desired size in the usual way by daylight or artificial light, according to the kind of enlarger you have.

RETOUCHING.—Would you be so kind as to let me know what you think of the enclosed retouching, and also point out faults?—J. H. W.

Second-rate only, but carefully done. Your work should be better modelled for the time taken. The likeness is well preserved, and the work clean. All prints sent for criticism should be toned and fixed, as otherwise they flatter the retouching.

RETOUCHING.—Would you kindly examine enclosed retouched proofs, and state the class of business such work is suitable for? The time taken to work each was from twenty minutes to half an hour.—RETOUCHER.

You send us a pretty heavy batch, and our space is valuable and has many claims upon it. Three of the unretouched and three of the retouched would have served your purpose. Your retouching is only suited to a second-class business, and if you aspire to higher things you should certainly devote more time to them, and so furnish better modelling and general finish. Your treatment of a variety of faces and ages is too similar.

COPYRIGHT.—1. I have offered the use, for 10s. 6d. of my photograph of fringed rose you have so kindly copyrighted for me, to the ———, and they reply, saying, "We will give you 10s. 6d. for photograph. In this case the photograph would belong absolutely to us, as we should claim the copyright." Is it possible for them to claim the copyright? If so, would this stop my further use of it? I thought a copyright meant it was the owner's property for ever, as long as he does not part with or sell the negative. 2. Also, how many

times could I use this copyright through various papers at a fee of 10s. 6d. for its use? A little enlightenment on the subject before I reply to ——— would very greatly oblige.—H. J. SHEPPY.

1. If you accede to the offer you part with your rights in the photographs. Of course, the parties are trying to trade on your supposed ignorance. Write and tell them they can reproduce the photograph in one issue only of ——— for a fee of 10s. 6d. 2. An unlimited number.

RETOUCHING AND OPERATING.—Please criticise the enclosed specimen of (1) retouching, and (2) operating—time twenty-five minutes. I am a printer, and only retouch occasionally. I have had three years' experience, and my age is twenty. (3) What salary do you think I should ask for twenty heads (such as specimen) per day of eight hours?—NOSMADA.

(1) Your retouching is of very poor quality, and entirely lacking in finish. Its best point lies in the fact that the likeness is respected, but the whole face needed much finer working and higher lighting. The specimen is a very easy face, presenting no character or difficulties to overcome. Retouchers submitting samples of work should choose a fair-sized cabinet, vignette, or larger negative, and one affording good scope for showing the treatment, and prints before and after retouching, toned and fixed, and for preference made on a glossy paper. You really require finishing lessons. (2) We should call your operating below the average. (3) You might ask 25s. per week as all-round assistant, but on your retouching alone, we doubt if you would receive that sum. Printers wishing to become retouchers should first make certain that the quality of their retouching warrants the change.

RETOUCHING.—I should esteem it a favour if you would kindly give me your opinion of enclosed specimen of retouching, and state where same might be improved?—FRANCIS.

Your retouching is very second-rate. It is not absolutely "dirty," but it is ragged in texture in places, and we should think that you either use a fat, blunt point, or work hastily. We should say you place too much retouching on, and so affect the modelling and likeness—very much to the detriment of the picture. Working slowly and *thoughtfully* very often makes for quicker finishing. Your greatest error is in flattening the general effect by wholesale removal of characteristic indentations and formation. The boldness of the nose is lost through over-removal of the shadow beside it. On the light side of face, and level with the moustache, there is a hollow-ness in the cheek that you have puffed out most unnaturally. The face line on shadow side is very ugly, and might have been pencilled into better form. The man has a certain amount of strength and knowledge of the world which you have done your best to remove. This is what you must look to in the future. Be more delicate in your gradation into the half-tones and shadows; and if you cannot secure with the ordinary lead you favour, then try a harder grade and very finely pointed, and work lighter in the touch. Try to get your finished effect with less pounding on of the pencil and with less effort. A few personal lessons, as you are not very far from town, and from a really skilled *teacher*, would benefit your style.

T. W. BARBER.—We are unable to locate the cause of the trouble but might do so if you would send us two or three slides to look at.

COPYING, ETC.—(1) Will you say if it is practicable to obtain from black and white prints or drawings negatives (either on dry plates or wet collodion) of sufficient density to give pure whites, reproducing same size—which implies but a short distance

between subject and lens, say 10 in., consequently bad illumination? I find difficulty, even in good light, with reflectors, white cloth over small camera, etc., R.R. lens. (2) Would you kindly name some practical manuals in any language for the processes of multiple impressions in printing ink half-tones from bichromated gelatine? I find Germans often give more precise and ample working details.—PHOTOPHIL (Tunis).

(1) The most even illumination should be obtained by placing the copy at an angle to the plane of the window, not too close to it. If artificial light is used good oil or incandescent gas lights placed on either side of the copy, and shielded from the lens, will give even illumination, but the exposure will, of course, be much longer. Use slow "transparency" or photo-mechanical plates, and develop with glycine, using the maker's formula. This should give you all the density you require. An alternative method is to use a slow plate, and considerably over-develop. Then reduce with Howard Farmer's reducer, which will clear the shadows, and the desired result will be obtained. (2) "Chromo-Lithographie," by Hesse, is a very comprehensive work now appearing in ten parts each Mk. 1.50), from W. Knapp, Halle-a/S., Germany. "Lichtdruck," by Albert, deals with collotype, and one or other of these two works should answer your purpose.

CRYSTOLEUM.—Would you kindly let me know if there is a special process, or what are the necessary requirements of a photograph intended for crystoleum painting.—J. McL.

An albumen print is the only one suitable for crystoleum. Emulsion papers are too heavily loaded.

DEXTRINE MOUNTANT.—I am given to understand that dextrine, when mixed with water and boiled, will stiffen again into a white paste suitable for mounting prints. Is that correct? I have tried to make paste in that way, but find after many days' waiting that the stuff is still a dark liquid.—C. MARSHALL.

If the best white dextrine is used, the paste will stiffen when cold. You have probably used common or brown dextrine, which will act as you say.

MOTTLED NEGATIVE.—I herewith forward a plate—one of three contact plates. Can you tell me the cause of them being spotted in that manner? All three are the same; they were exposed at the lamp and developed with 1 oz. pyro solution (usual developing solution), 3 drs. soda-sol., 1 dr. bromide potash sol. (25 grs. to the oz.). Developed very slowly by rocking for five or eight minutes, then left sitting in developer till fully developed.—I. M. P.

The markings are what you may expect if a plate is left in the pyro developer without rocking. The last part of the process has evidently caused the defect, which is particularly liable to occur with old pyro solution. Why use pyro-soda for positive transparencies? It is about the worst developer for the purpose. If you must use pyro, let it be pyro ammonia, but with other developers, imogen sulphite, for example, you will not get this mottling, even if the plate is not rocked.

USE OF LATE EMPLOYER'S NAME.—I shall be glad if you will kindly advise me in the following matter. About two and a half years ago I was employed by a well-known firm for several months. After leaving them I received a good reference, signed by the artistic manager, and confirmed by the general manager. May I now use the name of the firm as an advertisement in my own business—say, "late with . . ." without obtaining permission from the firm?—PHOTOGRAPHER.

It would not be illegal for you to do so, provided you do not use the firm's name in a more conspicuous way than you

do your own, or in such a way as would lead the public to infer that the business you are carrying on belongs to the firm. As it appears that you have not been in the employ of the firm for two years, and then only for a comparatively short time, we would suggest that you say "formerly with," instead of "late with."

COPYRIGHT BROMIDES.—(1) I have a series of early locomotive and automobile negatives, copied from engravings dated 1780-1840, which I wish to reproduce as postcards. Have obtained permission of client for whom they were copied provided I hold him good against copyright complications. I believe there were no copyright protections previous to 1862. Am I right, or do you think I run any risk? (2) Is it necessary to size a bromide enlargement previous to painting it in oils, or is the gelatine of the picture sufficient?—COPYRIGHT.

(1) There was no artistic copyright prior to 1862. We should say you are perfectly safe. (2) The print must be sized with a solution of fine white glue, applied warm with a soft brush. A test of the suitability of the print for colouring is to apply a little of the oil to one corner, and, if it sinks in, to give another coating of the size.

SHEET GELATINE.—Could you oblige me with the address of a firm who supplies sheets of thin clear gelatine, such as were employed years ago for transferring negative films?—W. GRIFFITHS.

Messrs. Penrose and Co., 109, Farringdon Road, London, E.C.

PHOTOGRAPHS OF PAINTINGS.—1. A friend of mine (a museum-director in Breslau), who writes at present a historical work, wants a photograph of picture 590 (King's Gallery), Hampton Court; see Law's catalogue, 1898. This picture is mentioned as "School of Memling, Head of a Man in an Oval (276)." Are there such photographs in existence, and who sells them? Or is it possible to get the consent of copying this picture, and to whom would I have to apply? 2. Would you be kind enough to tell me the address of the "Press Union," who, I am told, gives away authoritative tickets for photographers engaged in press-work?—BRANDES, LONDON.

Possibly, firms such as the Autotype Co., New Oxford Street, London, W.C.; Hanfstangl, Pall Mall East, London, W.; may have a reproduction of the painting, though we rather doubt it. Reference to "An Index of Standard Photographs" (published by Dawbarn and Ward, Ltd., 6, Farringdon Avenue, London, E.C.) might indicate the existence of a photographic reproduction. We cannot say whether permits to copy the pictures are granted, but you could find out by application to H.M. Office of Works, Westminster. 2. We do not know the "Press Union" in this country.

**** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

EX CATHEDRA.

An Editorial Millennium. Fraternal greetings are thick in the pages of our New York contemporary, "The Photographer," which has just celebrated the first anniversary of its birthday. We add our congratulations to those of Editors John A. Tennant, John Nicol, and Dundas Todd. Mr. Abel, of "The Photographer," has the distinction of producing the only photographic weekly in America, and his organ can boast a standard of excellence which places it among the three or four good photographic periodicals in the States. Mr. Tennant's "Note on Photographic Journals," is sternly practical and to the point, as might be expected from the office of "The Photo-Miniature." And his words are as applicable on one side of the Atlantic as the other. "It does not seem to occur to the average reader that the photographic journal is absolutely dependent upon the photographic worker for its news, for its freshness of information, and for its practical value. Unless there be a generous and large-hearted coming together between readers and editor, the photographic journal must necessarily lack the very qualities which the reader seeks in its pages." Let every reader of a photographic journal, he suggests, (1) name one particular point in which that journal lacks, and (2) send some practical hint or method which he can recommend as actually fulfilling its purpose. Then will be the editor's millennium. Any journal, concludes Editor Tennant, would then "be so completely changed that we would hardly know it. It would then be brimful of fresh and interesting facts, of formulae which would actually work, of methods and processes which would set hundreds of readers to improving their work, increasing their pleasure in photography and adding to their bank balances. You cannot have a live and progressive trade journal unless the readers build it brick by brick. All that the best editor in the world can do is to sift out the bad bricks from the good ones and supply the mortar to bind

the bricks into one harmonious and pleasing design—the journal itself."

Sodium Alum.

Statements in chemical text-books as to the double sulphate of sodium and aluminium are at variance, some writers describing the salt and others denying its existence. A recent paper before the Chemical Society, by Mr. J. M. Wadmore, makes it clear that sodium alum is formed on mixing molecular proportions of sodium and aluminium sulphates. One remarkable property of the alum is the behaviour of a hot concentrated solution. When suddenly cooled, a jelly first separates, and afterwards passes into a crystalline mass of partially dehydrated salt.

The National Photographic Record Association.

Without flourish of trumpets or blowing upon ram's horns, the National Photographic Record Association prosecutes its admirable work. At a council meeting held at the Royal Photographic Society on Thursday in last week, 335 prints were presented, bringing the total collected by the association to 3,504. Not a bad figure for only five years' work, done without ostentation by a comparatively small number of people. The council may congratulate themselves on the steady influx of prints from photographers scattered all over the country. Yet these contributions are not as numerous as they might be, and we would wish to see the association supported, in its work of recording the features, customs and institutions of this country, to a much greater degree. The annual meeting will be held at the Midland Grand Hotel, St. Pancras, on May 30, when the president, Sir Benjamin Stone, M.P., will take the chair. We have no doubt that anyone desirous of interesting himself in record work will be welcomed to that meeting, particulars of which, and of the association's work in general, can be obtained from the honorary secretary, Mr. George Scamell, 21, Avenue Road, Highgate, London.

Seasonable Precautions.

During the last ten days or a fortnight a considerable change has taken place, both in the strength of daylight and in the temperature. Over-exposure needs to be guarded against, and it is not a bad plan to make one or two exposures on quarter plates, say twice a week, in order to ascertain how much the exposures may be reduced. Notwithstanding the great latitude of the best modern dry plates there is nothing to be gained by giving three times the necessary exposure, as negatives so obtained are usually too dense, and consequently slower printers. So rarely does one come across frilling nowadays that no warnings or suggested precautions are necessary, but the fact should not be lost sight of, that increase of temperature in the developing

room has a material effect on the speed of development, and may lead to actual over-development. The increased brightness of the light, if daylight is employed for lighting the developing room, will also tend in the same direction. In lighting, especially where the subjects include such contrasts as black hats and light dresses, some care will need to be exercised to bring the contrasts within the compass of the plate. In all probability the light will need screening to a considerable extent from the white draperies, or they will be much over-exposed before detail is obtained in the dark portions of the picture.

Assistants' Certificates.

We learn that while the applications for certificates are not coming in to the Professional Photographers' Association so numerous as might be wished, the assistants who are applying are of a desirable kind. They have generally served an apprenticeship, or its equivalent, to a firm of good standing and have subsequent good records, and, so far, there has been no occasion to refuse an applicant. It must be gratifying to the committee to find that those who are the first to appreciate and avail themselves of the efforts to do something for their class are those who are likely to take a creditable position as members of the association later on.

* * *

Specialisation. On looking into the windows of the majority of photographers we find probably half a dozen printing processes represented, and in many cases represented badly. It is doubtful if in a moderate sized business the operator can with certainty make the best negative for any particular process which may have been selected by the customer, and it often happens that no variation is attempted; bromide, P.O.P., platinotype, or other print being made from the negative indiscriminately. We recently heard of a professional who charged the same price per dozen for all processes, and reserved the right to select the process most suited to the negatives after they were produced. This method might serve if prints were limited, say, to gaslight, bromide, or platinotype, but personally we should like to decide for ourselves whether our portraits would be glossy P.O.P. or sepia platinotype. A much better plan, in our opinion, is to specialise in one or at most two printing methods. Platinotype will give black and sepia prints; P.O.P., brown or purple prints with either glossy or matt surface; bromide enables the worker to supply matt or glossy black prints, or brown if the sulphide toning is used. Probably the greatest variation may be secured with carbon, and if worked on a large scale would not be appreciably more expensive than the other processes. There is no doubt that the standard of the work would be higher if one process were thoroughly mastered in all its little intricacies, and the odd customer who might chance to be lost because his pet process was not supplied would be more than compensated for by others attracted and secured by the general perfection of the results.

* * *

P.O.P.

We have referred to the mastering of the little intricacies of each process, and, to be more exact, let us take P.O.P. printing. This is a paper used in, say 90 per cent. of the businesses in the country, yet it is doubtful if more than 5 per cent. of those using the paper have any sound idea as to the uniform working of it, or know how to locate any difficulty when it occurs. The maker's instructions are more or less carefully followed, and in the majority of cases the results are passable. If prints are double toned, something or other is blamed, but how often is any systematic attempt made to ascer-

tain precisely what is wrong? How many workers even think of simply fixing a print to see whether the double-toning is a defect of the paper or of the manipulation. Again, when changing from one batch number of paper to another the usual method is just to go on as though the paper were exactly alike. Prints are toned as usual, and on drying may possibly be too cold or too warm in tone. Had the printer made two prints from the same negative, one on the old and one on the new paper, carefully marking each, and then fixed them without toning, he would have noticed a slight variation in colour, which would have warned him that the new batch needed rather more or rather less toning to keep the colour of the output uniform. In each of the processes these little refinements are possible, and can be managed where the energies, both mental and physical, are not scattered over half a dozen different methods.

POISONS USED IN PHOTOGRAPHY.

POTASSIUM BICHROMATE.

It is pretty generally known that many of the chemicals employed in photography are of a highly poisonous nature; indeed, some of them if taken internally would cause death within a very brief period, in some instances, and under some conditions, within only a very few minutes. Others produce very unpleasant effects on the skin of some of those who use them. It does not, however, follow that because a chemical may produce an ill-effect on one person that it will do so on another, although both may be employing it under precisely the same conditions. For example, some can use mercuric iodine with impunity, while others, on the contrary, experience extremely unpleasant effects even after using it for only a very short time. The same may be said with regard to bichromate of potash. It has no pernicious effect on some persons, while on others it has. We happen to know two or three carbon printers who have been working the process on a large scale, daily, for over a quarter of a century, and they have never experienced the slightest trouble from the bichromate, yet they take no special precautions against it. On the other hand, we have heard of instances where trouble has arisen after working the carbon process for a few months only.

We propose to deal with the characteristics of some of the poisons that are used in photography, with a view to pointing out how trouble arising from them may be avoided, or, at least, reduced to a minimum. We shall first deal with the bichromate of potash, as just now that is being more extensively employed in photography than at any previous period. In "Ex Cathedra," last week, we referred to two cases which ended fatally, through a solution of the salt having been drunk in mistake for beer. The incidents illustrate the danger of keeping these solutions where they can be mistaken for anything of a potable kind.

As regards the outward effects of the bichromate, and that is the more immediately interesting to those by whom it is employed, it may be explained that two distinct kinds of trouble may come about. The first is that arising from a cold solution, such as is used in sensitising carbon tissue, for example. The poison may enter a wound—be cut or an abrasion of the skin—and very painful results may follow. Here are the symptoms:—In the first place a smarting sensation is felt. This, if neglected, may be followed by inflammation, festering, and ultimately by ulceration. This latter sometimes results in a deep and painful wound very difficult to heal. But all trouble may

be avoided if, when the smarting is felt, the place be immediately washed under the tap and a little diluted ammonia applied. After this treatment the place should be well sucked for a few minutes. It is always a good plan, after sensitising with the bichromate, to rinse the hands in very dilute ammonia, then well wash them with soap and moderately hot water. This will at once remove the yellow stain from the nails and skin, as well as cleanse the hands from the bichromate. If the stain is allowed to dry, and is exposed to light, it is often very difficult to remove.

The second form of trouble is brought about by the action of a warm dilute solution of the salt, such as the water in reality becomes after a number of carbon prints have been developed in it. Here the trouble takes the form of what the late Dr. B. W. Richardson, who devoted a great deal of attention to the subject, described in the "Asclepiad" as a disease. The first symptoms are an irritation of the skin at the backs of, and between, the fingers. This is slight at first and is usually followed by the appearance of minute watery pustules. Next the skin dries and exfoliates in small bran-like scales. In more acute stages mattery pustules form, the skin dries up something like hard leather, and cracks into painful sores when the knuckles are bent. The skin then peels off in thick scales, not unlike the shell of a shrimp. During the progress of the disease the itching is intolerable; indeed, this is really the most painful part of it. With regard to a cure, none seems to be known so far as medical treatment is concerned. There is, fortunately however, a very simple and certain one. It is to avoid all further contact with the bichromate and Nature herself will work a cure, and that, too, in a surprisingly short time. This may be done by working for the future in india-rubber gloves. We have here described the disease in its most aggravated form, but there is no necessity to allow it to progress to that state if precautions be taken when irritation gives the first warning to the worker that he is subject to the disease.

When this irritation is first experienced the parts should have a little of the strong nitrate of mercury—the Unguentum Hydrargyri Nitratis of the Pharmacopœia—well rubbed into the skin at bedtime, and further contact with the bichromate avoided. The following lotion will greatly allay the itching:—Alcohol, six ounces; carbolic acid (pure), fifty minims; glycerine, four drachms. It is a good plan after working with the bichromate in any form to make it a rule to well wash the hands and wrists in tolerably hot water with a carbolic oil-soap, and a hard nail brush. This frees the skin from the bichromate and renders it supple when dry.

In "Ex Cathedrâ," last week, was given a calcium soap containing wax, which Dr. Schleich has suggested for application to the hands before commencing work with a bichromate. It looks promising, and is worth a trial. If it proves efficacious it will be far more convenient than having to work in india-rubber gloves.

In the above we have referred to the troubles that may be caused by the bichromate, but they are never likely to occur to any but those who work with it on a large scale, and constantly for a long time. Those who work the gum-bichromate process, or amateurs who produce a few carbon prints occasionally, need have no fear of ill-effects. We can say that we have never heard of an authentic case of an amateur, or of anyone working the carbon process on a small scale, suffering any inconvenience whatever, except when a strong solution of the salt has perchance got into a scratch or cut on the fingers, and that need only have been temporary had the place been treated as above. An old aphorism has it that "prevention is better

than cure," and it is always well when dealing with substances of a poisonous character to be as careful as possible in handling them. We must defer some notes on other poisons to a future article.

PRINTING PROCESSES.—III.

PLAIN OR SALTED PAPER.

It may seem somewhat superfluous to give any instructions for printing, but we recognise that there are a few matters which need to be explained to those who take up this process for the first time. In the first place the paper must not be too dry. It has even been recommended that it should be placed for a short time between damp blotting paper or placed in a box and this filled with steam. The danger consequent on such procedure is obviously silver stains on the negative, and we have never found it necessary except in extremely hot and dry weather to damp the paper. Even then if a sheet of the required size is placed on the bottom of an empty plate-box and a sheet of wet, but not dripping, blotting-paper be pinned to the lid and the box closed for about ten minutes, the paper will have absorbed quite enough moisture.

The negative should be a fairly plucky one and the stronger it is the brighter may be the light used for printing and vice versa. If the negative is thin, it is advisable to prolong the printing either by using a very weak diffused daylight, or weakening it by ground-glass or tissue-paper over the front of the frame. As regards the use of coloured glass for printing through, it may be at once stated that there is a good deal of misconception on this point, particularly now that the majority of negatives have a black and not a pyro-stained image. Further than this the amount of organic silver salt is relatively so small compared to the chloride and nitrate that the spectrum composition of the light does not matter much; it is the organic salts of silver that are more sensitive to green and blue-green than the chloride, the maximum of sensitiveness of which is in the violet and ultra-violet. Still as a coloured glass, particularly a chromium green or even a cathedral green, reduces to some extent the violet rays, and thus weakens the light, the prints may show greater brilliancy if such a filter is placed over the frame.

In the matter of the depth of printing there is no guide; it is dependent on the toning bath and on the actual colour or tone that is required. The more nearly this is to approach black, the deeper must be the printing; paper that has been sensitised with an ammoniacal solution, or has been fumed, must be printed much deeper than the acid silvered paper. Still, one may safely say that printing should be continued until the highest light to be approximately white in the finished print is fairly deeply tinged.

After printing, the prints should be well washed in running water or in frequently changed waters. As there is practically no film to retain the silver salts, they wash out rapidly and the waters should be changed at least every two minutes, till the print drains clear. To obviate this washing, the whole of the silver salts in the paper may be converted at once into insoluble chloride. To this end the prints are immersed, without previous washing, in a salt bath, but the solution must be weak, not stronger than 1 in 80. On the whole it is preferable to wash rapidly in pure water.

Any toning bath may be used, but as there is no protective coating to the image, it tones very quickly, and overtoneing, which is always known by the flat grey sunken-

in look, soon takes place. Therefore, no matter what formula is adopted, it must never be stronger than one grain of chloride of gold to the pint. The simplest bath of all is the following:—

Chloride of gold	1 grain.
Prepared chalk	$\frac{1}{4}$ oz.
Water	20 oz.

Shake well, allow to stand till clear and use the clear solution.

Gold nearly always gives tones which have a violet tinge, that is to say they are those known for so many years as "photographic browns" "photographic purples." A much more pleasing tone can be obtained by using platinum as the toning agent. The tones given by this are yellowish-browns tending towards black, some of which are called sepia, but they are not sepias at all.

For platinum toning any formula may be adopted, but it should not contain nitric acid, which reduces the intensity considerably; it is far preferable to use the ordinary phosphoric bath weakened, as follows:—

Potassium chloroplatinite	2 grains.
Dilute phosphoric acid	$\frac{1}{4}$ oz.
Water	20 oz.

and for this bath and in fact all platinum baths, the prints should be immersed for five minutes in the above mentioned salt bath.

Pure black tones are not readily obtainable on plain paper, but rich warm blacks may be, either by first toning the prints lightly in the gold bath suggested above, and then washing and immersing in the platinum bath, or by using the platinum bath direct. This may seem troublesome, but it is easy and takes but little time. There is yet another method that may be adopted, and that is to immerse the prints in the gold bath and as soon as they begin to change colour, remove them and add to the bath some chloroplatinite solution and again immerse the print. The chloroplatinite reduces the gold and possibly is itself also reduced, with the result that very rich deep tones are obtained.

There is one point in connection with the use of platinum that should not be overlooked, namely, the extreme facility with which yellowing of the whites is caused. Too slow a toning bath will always give this, and, therefore,

some attention should be paid to the temperature of the bath. About 65 deg. Fahr. is right, or if one does not care to fiddle about with the temperature, then as a general rule it may be stated that if in three minutes there is not a decided toning action, the bath must be at once strengthened or heated.

As regards the fixing of the prints we will, notwithstanding the danger of being accused of reiteration, point out that there is no protective medium in plain salted paper, and therefore the hypo bath must not be used so strong as it usually is. A 10 per cent. solution of hypo is quite strong enough, and five minutes' fixing is sufficient provided the bath is not chilled. A freshly mixed hypo bath has a very low temperature and fixes slowly; but at the temperature of an ordinary room, say 56 deg. to 60 deg. Fahr., the above bath is quite strong enough and will do its work in the time above prescribed.

There is only one further point which we must insist on, and that is the complete elimination of the platinum bath prior to fixing. When gold is used as the toning agent, the toning bath is always alkaline, or should be, and if the print is dropped direct into the fixing bath no harm is done; any gold hyposulphite that may be formed is perfectly soluble. But in the case of platinum, the toning bath is acid, and if traces are introduced into the fixing bath the hypo is decomposed and general yellowness may be caused. Also, platinum hyposulphite is an extremely insoluble salt, and is one of the best means of producing general yellowness and patches.

We trust that these few notes on plain paper printing will be acceptable to many and lead some who have not yet tried the process to experiment with it. Considering the enormous number of printing papers now commercially available and the various surfaces also to be obtained, it would seem somewhat supererogatory to direct attention to yet another; but there are many to whom the home preparation of a paper or other material presents considerable charm, and there is no doubt that suitable choice of a particular class of paper and the home sensitising on the lines we have laid down give opportunities for the exercise of individual taste from which a photographer may expect benefit. We cannot conceive of the process being extensively employed, but whilst the bulk of a studio's output is gelatine, collodion, platinum, carbon or bromide, there may yet be room for occasional and effective use of plain paper.

PAPERS ON PRACTICAL PHOTOGRAPHIC OPTICS.

III.

THE third article of a short series. The two previous contributions (THE BRITISH JOURNAL OF PHOTOGRAPHY, April 28 and May 5) dealt with "Focussing Scales and Depth of Field," and "Lens Calculations without Arithmetic." Next subject, "The Speed of Telephoto Lenses when Employed on Near Objects."

Let A' A A'' be three points on the axis of a lens, and let rays proceeding from them be brought to a focus at B' B B'' respectively. Let C be the centre of the lens, let its diameter be denoted by a , its focal length by f , and let $CA' = u'$, $CA = u$, $CA'' = u''$, $CB' = v'$, $CB = v$, and $CB'' = v''$. Then by the fundamental equations connecting conjugate foci we have:—

$$\frac{1}{u'} + \frac{1}{v'} = \frac{1}{f} \quad (1) \quad \frac{1}{u} + \frac{1}{v} = \frac{1}{f} \quad (2) \quad \frac{1}{u''} + \frac{1}{v''} = \frac{1}{f} \quad (3)$$

These equations generally hold only when the lens is an indefinitely thin one, but if we measure u , v , not from C but from the nodal points, they will be true, and the conclusions to be drawn from the subsequent calculations will not be vitiated by taking the simpler case instead of the more accurate one, which would render the diagram more complicated.

It is evident that if we place the ground-glass focussing screen so that it passes through B , A will be represented by a point, but A' by a disc (called a circle of confusion), formed by the rays which after passing through B' have begun to diverge, and A'' by another circle of confusion formed by rays which have not yet come to a focus. Let us call the diameter of the former d' , and that of the latter d'' .

Then by similar triangles, D' B' B, E' B' C:—

$$\frac{d'}{a} = \frac{BB'}{B'C} = \frac{BC - B'C}{B'C} = \frac{v - v'}{v'}$$

whence

$$d' = \frac{a(v - v')}{v'}$$

But from (1) and (2)

$$\frac{1}{u} + \frac{1}{v} = \frac{1}{u'} + \frac{1}{v'}$$

or

$$\frac{1}{v} - \frac{1}{v'} = \frac{1}{u'} - \frac{1}{u}$$

whence we get

$$\frac{v' - v}{v'v} = \frac{v(u - u')}{uu'}$$

and consequently

$$d' = \frac{av(u' - u)}{uu'} \quad (3)$$

Again, from similar triangles, D'' B'' B, E' C B'':—

$$\frac{d''}{a} = \frac{BB''}{CB''} = \frac{B'C - BC}{CB''} = \frac{v'' - v}{v''}$$

from (2) and (3), proceeding in a similar way, we get:—

$$\frac{v'' - v}{v''v} = \frac{v(u - u')}{uu''}$$

and

$$d'' = \frac{av(u - u')}{uu''} \quad (4)$$

and from (2) we get:—

$$v = \frac{uf}{u - f}$$

Substituting this value for v in (3) and (4) we get:—

$$d' = \frac{af(u' - u)}{u'(u - f)}$$

and

$$d'' = \frac{af(u - u')}{u''(u - f)}$$

If, in accordance with the usual custom, we express the aperture as a fraction of the focal length and put $a = \frac{f}{n}$, these two

equations will become:—

$$d' = \frac{f^2(u' - u)}{nu'(u - f)} \quad (5)$$

$$d'' = \frac{f^2(u - u')}{nu''(u - f)} \quad (6)$$

These are the equations from which we shall derive certain conclusions.

Suppose we wish to focus A accurately, and to have an equal amount of diffusion in the images of A' and A''.

Then putting the values for d' and d'' in (5) and (6) equal to one another, we get:—

$$\frac{u' - u}{u'} = \frac{u - u''}{u''}$$

or

$$1 - \frac{u}{u'} = \frac{u}{u''} - 1$$

whence

$$\frac{1}{u'} + \frac{1}{u''} = \frac{2}{u}$$

showing that $\frac{1}{u}$ is the arithmetic mean between $\frac{1}{u'}$ and $\frac{1}{u''}$, or u the harmonic mean between u' and u''. Or, to state the matter more simply:—

$$u = \frac{2u'u''}{u' + u''}$$

That is, in words, u is equal to twice the product of u' and u'' divided by their sum.

This result is of practical use, as it tells us the distance from the lens of the point intermediate between two others that we must focus in order that these two may be represented with equally sharp definition.

Suppose, for example, we are using a camera with a focussing scale, and we want to focus so that objects at ten and thirty yards may be equally sharp. The equation shows that we must set the lens so that an object at $\frac{2 \times 10 \times 30}{10 + 30}$ or $\frac{20 \times 30}{40}$, or fifteen yards, is in absolute focus.

It will be seen from this example that the required point is nearer to the nearer object than to the more remote. We can show that this is always the case.

Suppose, as in our diagram, u' is greater than u''. Then, if A' and A'' are the two given points, and that A is the point we have to focus:—

$$AA' = u' - u = u' - \frac{2u'u''}{u' + u''} = \frac{u'^2 - u'u''}{u' + u''}$$

$$AA'' = u - u'' = \frac{2u'u''}{u' + u''} - u'' = \frac{u'u'' - u''^2}{u' + u''}$$

Then

$$AA' - AA'' = \frac{u'^2 - 2u'u'' + u''^2}{u' + u''} = \frac{(u' - u'')^2}{u' + u''}$$

As this difference is always positive, AA' is greater than AA''.

Returning to equation (5). We may divide numerator and denominator by u', and we get:—

$$d' = \frac{f^2 \left(1 - \frac{u''}{u'}\right)}{n(u - f)}$$

Now if u' is made infinite, we must neglect $\frac{u''}{u'}$ and $d = \frac{f^2}{n(u - f)}$

This will give us the diameter of the circle of confusion of the image of a point at a distance u, when the lens is set so that objects in the extreme distance are in absolute focus.

It is generally assumed that if d does not exceed 1-100th inch, an ordinary eye will not detect want of sharpness if the photograph is held at the nearest distance of ordinary vision of a normal eye—that is, about twelve inches.

From this, or some equivalent, formula, the tables of distances beyond which all objects are practically in good focus, when the lens is set so that distant objects are in absolutely correct focus have been calculated.

To take an example. Suppose the lens is one of 5 in. focus, and the stop used is the one marked f/8.

Then

$$\frac{1}{100} = \frac{5^2}{8(u - 5)}$$

whence

$$u - 5 = \frac{2,500}{8} = 312\frac{1}{2} \text{ in.}$$

$$u = 317\frac{1}{2} \text{ in.} = 26 \text{ ft. } 5\frac{1}{2} \text{ in.}$$

Sir David Solomon's table, published in the BRITISH JOURNAL ALMANAC (p. 1,158), gives 27 ft., and Dr. Higgins's 26 ft. Our formula gives in like manner, 13 ft. 8 in. for a lens of 4 in.

working at $\frac{1}{10}$ J. H. Dallmeyer's table, 14 ft.

But supposing instead of focussing for a distant object, we focus for an object at the distance given by our equation. Let us see what would be the diameter of the disc of confusion for an object at infinity. First we get $u - f = \frac{100f^2}{n}$, substituting this

in the equation:—

$$d' = \frac{f^2(u' - u)}{nu'(u - f)} \\ d' = \frac{f^2(u' - u)}{nu'(u - f)} = \frac{u' - u}{100u'} = \frac{1 - \frac{u}{u'}}{100}$$

we get

or, making u' infinite $d' = \frac{1}{100}$.

That is to say, according to our assumption, the most distant objects will be practically in focus.

Now finally let us determine what is the nearest object that will be in focus.

We have already shown that if u' , u , and u'' , are the distance of three objects, and if we focus accurately the object at the distance u , then the one at distance u' will be in as good focus as one at distance u'' , provided that $u = \frac{2u'u''}{u' + u''} = \frac{2u''}{1 + \frac{u''}{u'}}$.

Now make u' infinite, and we get $u = 2u''$, or $u'' = \frac{u}{2}$.

This shows that if instead of focussing so that the object at an

infinite distance is in absolute focus, we focus so that the circle of confusion for a point at infinity has a diameter not exceeding $\frac{1}{100}$ in., then an object at only half the distance given in the

tables will also be in appreciable focus.

To return to our numerical example. If we have a 5 in. lens working at $f/8$, and first focus an object on the extreme distance, and then rack out as far as possible without visibly impairing the definition of this object, we shall find that all objects beyond about 13 ft. will be in appreciable focus at the same time.

T. PERKINS, M.A.

MODERN CHEMISTRY FOR PHOTOGRAPHIC WORKERS.

III.—THE APPLICATION OF THE IONIC THEORY TO CHEMICAL REACTIONS.

Anions and Kations.

We have seen that if salts are dissolved in water they may be imagined to split into parts called ions, these ions consisting of atoms of the elements, which differ from ordinary atoms in that they carry an electric charge. Broadly, it may be said that all salts split into two parts, and these two parts constitute what we are accustomed to consider the basic and acidic constituents of the salt. For instance, potassium chloride splits into potassions and chlorions, while copper sulphate splits into cuprions and sulphions. Of these two parts, the basic or metallic ion has a positive charge, and is consequently deposited on the negative kathode in an electrolytic cell, while the acidic ion has a negative charge, and is liberated at the anode.

The metallic ions are consequently termed kations* and the acidic ions are termed anions*. Thus hydrogen, sodium, copper, silver, gold, etc., form kations with a positive charge, while oxygen, chlorine, bromine, sulphur, etc., form anions with a negative charge. But ions frequently consist, not of single atoms, but of groups of atoms associated with an electric charge. Thus ammonium sulphate splits up according to the equation:—

Giving rise to two ammonium ions with one positive charge each and one sulphate ion with two negative charges.

In the same way, we can get an element which generally forms kations forming part of a complex anion. Potassium ferro-oxalate, for instance, which is the active principle of the ferrous oxalate developer, dissociates according to the equation:—

and it is this ferro-oxalation with two negative charges which really forms the developing substance.

Reactions are Between Ions.

While all this discussion of the state in which salts exist in solution is of very great interest, it is only when it is applied to chemical reactions that the real importance of this point of view becomes evident. It is, indeed, not too much to say that the development of the ionic theory has caused us to alter entirely our ideas as to chemical reaction, and has greatly changed the very equations in which we have been accustomed to express the reactions which occur. A great number of formerly complicated equations have been so altered by the ionic theory as to become expressible simply as a shifting electric charge.

(* Ana=up; kata=down; ion=mover; hodos=a way.)

It is clear that the great majority of reactions, especially those occurring in water solution, occur between ions, and not between molecules at all. All chlorides in water solution, for instance, react with silver nitrate solution to precipitate silver chloride. If we considered the subject from the older standpoint, it is not at all clear why all chlorides should behave alike in this respect. The ionic theory, however, gives us the clue at once—silver nitrate is a test, not for chlorides, but for chlorions in solution.

Let us think what happens. The old form of the equation is

Ionise both sides of this equation, we get:—

The AgCl is unionised because it is insoluble in water and is consequently precipitated. We can see that on both sides of this equation we have potassium ions and nitrate ions which have not been changed, so that we can more simply write the equation:—

That is to say, silver ions form a test for chlorions because the charges are neutralised, insoluble silver chloride being precipitated.

The Ions of Acids and Alkalies.

In the same way, if sulphuric acid acts on zinc, we can write the reaction:—

Ionising

or more simply,

That is, the reaction is simply a transfer of two positive electric charges from two hydrogen ions to one zinc atom.

This leads us to another discovery. Acids owe their properties to the presence of hydrogen ions, and the strength of the acid depends on the number of these hydrogen ions present. In the same way, alkalis owe their properties to the presence of hydroxyl ions, thus:—

The Action of Solutions on Solids.

We next come to another question. What happens when a solid is acted on by a solution? If we pour dilute hydrochloric

acid on marble we get off bubbles of carbonic acid gas. Since we must consider our hydrochloric acid as ionised, we can most simply represent the facts by imagining the marble to be surrounded by a film of dissolved calcium carbonate, so that the reaction proceeds between this dissolved marble, which, because it is in dilute solution, will be very completely ionised, and the hydrogen ions, according to the equation:—

As fast as the calcium carbonate is decomposed in this way more dissolves from the marble, and so the reaction progresses.

Photographic Development.

Development may be considered to take place in exactly the same way. In this case we have silver bromide going into solution and being ionised into silver ions and bromions, while in the case of ferrous oxalate, the ferro-oxalate reacts.

Development with ferrous oxalate may therefore be represented by the equation:—

This last ion couples up at once with an oxalate:—

so that development with ferrous oxalate is simply the neutralisation of a charge on a silver atom at the expense of one of the charges of the ferro-oxalate. Of course, the discharged silver atom is at once precipitated as metallic silver. In the same way exactly hydroquinone is ionised, but with this difference, that hydroquinone can only form ions in the presence of alkalis. This, in fact, is the reason why alkalis are necessary for development with the phenolic organic developers, not in order to soften the gelatine or anything of that kind, but simply to form the ions by which development is performed.

The developing ion of hydroquinone is formed according to the dissociation equation:—

and since hydroquinone is a very weak acid indeed, this reaction is only possible in presence of a strong base, such as soda or potash.

It will be seen that this hydroquinone ion can easily react with two silver ions according to the equation:—

that is to say, the hydroquinone ion loses two electric charges

—which neutralise the charges on two silver ions—and forms quinone, the well-known oxidation product of hydroquinone.

In the same way pyrogallol, in presence of alkali, will be ionised, giving an ion

which has three negative charges; but Valenta has suggested that if only a small quantity of caustic alkali be added another ion,

with only one negative charge, and with very different developing properties, may be obtained.

Since the developing properties of a solution depend upon the number of active ions which it contains, it is clearly a matter of importance to be able to measure the amount of ionisation which it has undergone. As a general rule, it may be observed that the more dilute the solution the greater the ionisation, until at infinite dilution the ionisation will be complete. The amount of the ionisation may be very easily measured by means of the osmotic pressure, as has previously been explained, the osmotic pressure being calculated from the difference of freezing or boiling point existing between the solution and the pure solvent.

If, for instance, we have a solution of potassium bromide, and, on measuring the osmotic pressure we find that it is 1.4 times that which would have been calculated from the formula K.Br., it is clear that the solution contains 1.4 times too many molecules, or that 40 per cent. of the molecules have split into two, that is, become ionised. There is, however, another way of measuring the state of ionisation of a solution. We have seen that the conductivity which a solution exhibits towards an electric current depends solely upon the ions which it contains. Consequently we can calculate the state of ionisation of a solution by measuring the conductivity which it possesses. At infinite dilution we assume that all the salt which we have introduced into the solution is completely ionised, and, consequently, if at very great dilutions the gram gives us a conductivity of 1, while at the dilution at which we desire to determine the ionisation we have a conductivity of .6, we conclude that only 60 per cent. of the molecules are ionised. Since even completely pure water has been shown by Köhler to have a small conductivity, we may conclude that water itself is very slightly ionised according to the equation:—

It may be remarked, however, that practically nothing is yet known as to the state of ionisation of the usual developing agents, and in most cases their oxidation products are undetermined.

C. E. KENNETH MEES, B.Sc., F.C.S.

THE WEEK IN HISTORY.

Daguerreotype in 1826.

WHEN Daguerre and Niepce entered into partnership on December 14, 1829, one item of the compact between the two inventors was that each should disclose to the other the progress made in his researches. It is beyond doubt that Niepce did actually hand to Daguerre an account of the process which represented more than ten years' experiment. It is his "Notice sur l'Héliographie," and Daguerre published it in 1839 with a number of sharp footnotes drawn up to show that the Daguerreotype process had nothing in common with Niepce's methods. What Daguerre disclosed to Niepce I have never been able to discover. In April, 1827, Daguerre sent to Niepce a print in sepia, which he alleged to be produced by his photographic process. Dr. Lindsay Johnson, in the "Photographic Journal" for March of this year, refers to this offer of Daguerre's as a successful "bait," and it certainly is doubtful whether Daguerre had any sort of a process at this time. The deed of partnership drawn up two years later only credits Daguerre with "a newly-designed camera," and there is no evidence to support the view that Daguerre had made any progress whatever towards the realisation of his cherished ideal—the fixation of the camera image.

There is one curious fact, however, which may be set down. On February 18, 1839, a paper was read by Biot before the Paris Academy of Sciences, describing how to prepare a sensitive photographic paper by a process strongly resembling that of Wedgwood, forty years before. This process, Biot declared, was used by Daguerre in 1826, and I have seen it stated that a description of it was handed to Niepce on May 21 of that year, though I confess I have not been able to confirm the correctness of the statement. The process consisted in treating paper first with feebly acid "ether muriatique" (from the action of hydrochloric acid on alcohol), and then with silver nitrate. There was no fixing process. The copies had to be kept in the dark.

Roll-film of Fifty-one Years Ago.

Who says that focussing the picture when using roll-films is original with the inventors of the present decade? It was one of the features of the very first roll-holder—that of Spencer and Melhuish. They provisionally patented their apparatus on May 22, 1854, but they allowed the patent (No. 1139) to lapse. The specification, however, is for an appliance "by means of which a person may more conveniently carry out and use any quantity of prepared paper or surface in such manner as to obtain in succession a series of photographic pictures, the parts of the paper or sensitive surface, not for the time being in use, being rolled up within the frame for the camera. For this purpose the frame in which the prepared surfaces are employed is fitted up with two rollers, and the sensitive surfaces are connected together so as to produce a long sheet, suitable for receiving in succession several or many pictures; and in using the apparatus, after one picture has been taken, that part of the prepared sensitive surface is wound up on to one of the rollers, and a fresh quantity of the prepared surface, suitable for receiving another picture, is unwound off the other roller, and so on, till all the prepared paper or surface on the roller has been used."

EXHIBITION of the West Surrey Photographic Society.—At the recent Exhibition of the West Surrey Photographic Society (the seventeenth annual) the awards were as follows, the judges being Messrs. A. Mackie and W. Rawlings:—Silver plaque for the best picture in exhibition, "From the Sunny South," Mrs. W. H. Goy. Champion Class (members who have previously won awards at this

But note the ingenious way which the patentees propose to focus the picture with the sensitive surface *in situ*:—"In some cases, particularly when using waxed paper, in place of focussing on to a plate of ground glass I focus directly on to the prepared surface, having previously placed a plate of yellow glass in front of the lens, to prevent the light from injuriously affecting the surface, and also another plate of yellow glass behind the paper with a similar object." The slow papers of the fifties had some advantages after all.

Varieties of Roll-holders.

A correspondent lately drew my attention to some roll-holders other than those I have mentioned in these articles, and though it is not my object to deal exhaustively with every piece of apparatus from the historical standpoint, I may extract briefly from my good friend's notes. In the year 1857 C. J. Burnett described a roller-slide for the exposure of lengths of sensitised waxed paper (Sutton's "Photographic Notes," 1857, p. 203). His idea included panoramic pictures, and he suggested the photographing of the complete horizon with a view to preparing in this way the panoramic exhibitions which were popular in these days.

Another arrangement was that of Silvy, patented in 1867 (No. 2,170), by which the complete circle was photographed (see Sutton's "Photographic Notes," 1867, p. 292). Silvy's apparatus was primarily for panoramic work, and he does not appear to have troubled about the daylight changing of sensitive film or paper for ordinary photography.

It is worth mentioning that Silvy actually uses the term "cartridge": "Thus the operator carries in his pocket a cartridge containing a long roll of sensitive paper, and when he wishes to take a view he inserts the cartridge within the camera, connects a simple mechanical contrivance with it, unrolls the paper against the curved glass, and exposes it."

Then there was the film or paper chamber of Thomas Wiseman ("The Illustrated Photographer," April 29, 1870), which was a sort of film camera worked in conjunction with a reversing mirror, by which negatives suitable for single transfer printing were obtained, though why they wanted to make reversed paper negatives I am at a loss to say.

Dry Collodion Again.

In the fifties and sixties of the last century experimenters were busily at work in attempts to rob wet collodion of its outstanding drawback—the need of exposing the plate immediately after exposure. I have already referred to Gaudin's efforts in this direction, and I may record a paper of his published in "La Lumière," for May 22, 1854, in which he recommends a sensitising bath of 5 per cent. silver nitrate containing 5 to 10 per cent. of zinc nitrate and the same proportion of white sugar. These hygroscopic bodies in the collodion film preserved the plate for several hours, and, after a further treatment in a silver bath after exposure, it was developed with a strong iron developer without markings from its protracted retention in a moist condition before exposure. The process is practically that of Crookes and Spiller, to which I referred in "The Week in History" for April 28.

HISTORIUS.

exhibition).—Bronze plaques: "Snow and Fog in January," A. Lockett, "Hay Time," H. Wright; highly commended, "Polyscope Designs," R. H. Baskett. Class II. (members who have not previously won awards at this exhibition).—Bronze plaques: "Daffodils," W. H. Goy, "On the Cornish Coast," V. Nichols. Lantern Slides.—Bronze plaque: "Russet Leaves of Autumn," W. H. Goy.

MARINE PHOTOGRAPHY.

THE opening of the one-man show of "Marine Photography and Wave Studies," by Mr. F. J. Mortimer, F.R.P.S., at the Royal Photographic Society, on Tuesday last, gave that worker an opportunity to make some practical remarks on the subject of photography of the sea. He said that the first aim of the marine photographer should be to secure a truthful rendering of the actual scene of motion, endeavouring, if possible, to catch the picture at the right moment, when the composition had assumed its most likely correlation of parts. A quick eye was essential, and the mind had to be made up rapidly, as there was no chance of exactly the same combination of form appearing again.

Different Kinds of Waves.

The difference in wave forms were remarkable—locality and circumstances had much to do with their formation. Natural and regular waves were only to be found far at sea, away from any disturbing obstructions in the shape of rocks. Waves nearer the coast far exceeded in violence and size the natural deep sea waves, and assumed far more fantastic shapes. Breakers and surf were the result of the upper part of the wave being urged on by wind or storms, while the lower part was obstructed by rocks, sand, weeds, or adverse currents. The spray was carried by the wind and its own impetus to great heights, and proved the worst obstacle to be overcome when taking photographs among the breakers. It not only rendered the lens temporarily useless, but would soon entirely spoil any exposed brass-work on the camera.

Difficulties and Costume.

The great trouble in all pictures of big waves, whether at sea or among the rocks, was the lack of scale; and the only way to carry conviction was to photograph the same scene later in calm weather, showing the same rock formation, but with a man or boat included to convey the idea of the relative scale of the wave in the storm picture.

A tripod was of very little use in this sort of work, and not much rope was offered or possible for focussing on the ground glass. The worker, therefore, should accustom himself to holding the camera readily in the hand at eye level, by means of a strap handle, and aiming it at the scene to be photographed. The ball of the pneumatic release of the shutter could be held between the teeth, and smartly bitten at the instant of exposure.

A certain amount of physical strength and recklessness was necessary for the wave photographer, as occasional bruises and broken apparatus, to say nothing of frequent drenchings, were very likely to occur. In some cases a companion and a stout rope were essentials for success when working among dangerous rocks.

Oilskins and sea-boots were the only possible kind of clothes that could stand the wear and tear of the work, and Mr. Mortimer suggested oilskin trousers, short coat, and sou'-wester worn over a lightannel outfit as the best costume. In any case, the ordinary mackintosh was worse than useless on very rough days, and would only prove a hindrance.

Points of View.

It would be found a mistake to point the camera down when standing at any height above the sea level, with the idea of including the more foreground or to make the waves appear bigger. The correct effect would be that the water was running uphill to the horizon, and anything in the shape of boats, etc., in the distance would appear as if stuck on the top of a wall.

An interesting series of wave and rock pictures could be easily obtained on a suitable day without moving a great distance from a chosen spot. First of all, a great variety of lighting presented itself according to the time of day. Then, by slightly altering the direction

in which the camera is pointed, pictures that showed considerable difference in character could be obtained. While perhaps the greatest variety of all could be obtained from about the same standpoint by taking a series of pictures at different states of the tide.

Lenses of different focal lengths were also useful to give different renderings to the same subject, but a lens of the greatest focal length that could be reasonably used should always be employed. Telephotography was not very useful in rough weather, owing to the cumbersome apparatus and vibration caused by wind, etc. A note of warning was necessary to the photographer climbing over the slippery rocks, to sound all footholds before venturing forward, and also to see that there was a safe line of retreat before going too far out on the rocks when the tide is rising.

Studying the Subject.

Fine wave studies could often be obtained on windless, sunny days, when a strong ground sea was running. The ground sea, usually in the form of huge rollers, were at the time the only indication that reached the land of a storm far at sea.

Before attempting to photograph waves breaking on to rocks, the moving masses of water should be carefully studied for a time until the character of the advancing wave could be gauged to a nicety, and its point of breaking foretold. There was no doubt that an extra big wave recurred at more or less regular intervals, and the interval became more certain when the rollers advance from a settled direction—wind blowing inshore and tide rising. It would probably be found, however, that if there was a cross current, or if the rocks against which the waves were dashing were on a jutting headland, the breakers occurred first from one direction and then from another a point or two to the right or left. They approached the rocks and broke alternately, and it would be noticed that frequently both masses of water would meet and break simultaneously, and an extra big wave would result. This was the opportunity to take advantage of to secure the most striking result.

Exposure.

As regards the actual moment of exposure, it would be found that in every wave form, when it strikes amongst rocks, there was an instant when the mass of water is at its maximum height, and remains stationary, suspended in mid-air. That was the moment the exposure should be made, and far finer results will be obtained than with indiscriminate "potting" at the rushing water. As regards the lens, a high-class anastigmat was not absolutely necessary, owing to the high actinic quality of the light usually present. The ordinary R.R. lens, stopped down, was generally good enough for most work; and as a rough guide it would be found that with a rapid plate (about 200 H. and D.) $f/16$ and 1-100th of a second would give a fully exposed plate at noon in early spring. In bright sunshine a smaller stop could frequently be used, or a shorter exposure given.

The bright, sunless day, with driving wind clouds, was possibly the ideal day for wave photography, and frequently fine results were obtainable on dull, grey days.

Hints on Apparatus, etc.

Very little tripod work was practicable in rough weather, so it was best to always use the camera in the hand, and use a direct vision view-finder of large size at the eye level.

Half-plate was quite large enough for all purposes, and in all cases the entire camera, etc., should be enveloped in a protective waterproof covering of oilskin or rubber, made to fit, and leaving only apertures for the lens and shutter release. Flaps should be made to button down all round, to get at slides and set the shutter, etc., and even then the camera and lens should not be exposed to the

direct action of the flying spray more than necessary. A frequent coating of vaseline on all brass binding, leather, and woodwork would do much to ward off the attacks of the salt water and air.

Although it had been found possible to occasionally secure wave pictures with an exposure of 1-15th of a second, Mr. Mortimer found that 1-30 to 1-130th were the exposures that were most likely to give good results, and to convey the idea of motion well.

Of the four types of shutters tried, viz., the metal diaphragmatic, time and instantaneous roller blind, the foreground and focal plane shutters, the first was useless for wave work, being all metal, and also leaving the front of the lens exposed; the other three were all good at times, particularly the foreground shutter, when there was a dark, rocky foreground and clouds in the sky. The focal-plane shutter, however, gave a rendering to these subjects that could not be surpassed by the other shutters—that is, provided it was not used at too great a speed, in which case the water would appear frozen, or look as though stamped out of tin. The focal-plane shutter scored most on dull days, owing to its high efficiency. A comparatively smaller stop could be used with this shutter with approximately the same exposure given by the before-lens variety, as in practice it would be found that it admitted about three times the amount of light with a given exposure than any other form of shutter giving the same approximate exposure.

In all cases the lens should be well protected from flying spray, and the best type of camera for the work should have a focal-plane shutter at the back and a before-lens shutter in front. The exposure would then be made by uncovering the lens, releasing the focal-plane shutter, and quickly covering the lens again, an operation that could be accomplished in about one-second.

Practical Work.

The camera should not as a rule be pointed straight at the incoming breakers, or the picture will appear to lack stability, and the repetition of horizontal parallel lines of rollers was displeasing, while those breaking in the immediate foreground would have a "lace-curtain" effect. The breakers or rollers should therefore always be taken, if possible, at an angle if the most pictorial effect was aimed at. The shore or rocks should run more or less diagonally across the base of the composition, and the breaking wave should be taken more in "profile" than "full face." The idea of action was thus better conveyed. In reference to telephotography for this subject, practical experience pointed to the fact that the conditions were altogether adverse to its employment, particularly as very little focussing or composing of the subject could be attempted on the ground glass, and the camera could not often be used on a tripod or the lens left uncovered for long.

If it was absolutely necessary, a piece of thin glass, such as a lantern-cover glass, could be held temporarily over the front shutter with elastic bands, and the picture composed through it, but focussing should not be attempted with this glass in position.

The late autumn or early spring were the best times of year for big wave photography, and the whole of the winter was also available, but usually the days were so short that not much work could be accomplished.

Plates and Films.

Films and colour-sensitive plates were more liable to attack by the salt air than ordinary plates. Plates and films should therefore be very carefully packed both before and after exposure, wrapped in oiled paper and kept in an air-tight tin box, if possible. Otherwise, if kept for any time before development, mould spots or even a salt crystallisation would appear, even after fixation, washing, and drying in a damp salt atmosphere. The plates should not be kept in the dark slides longer than was absolutely necessary.

Colour-sensitive plates and screens would be found useful at times,

when all else had failed to render the relative tone values of rocks and waves satisfactorily, but they were not always necessary, as in most instances a fairly quick ordinary plate (backed) and foreground shutter would prove sufficient. The light was so actinic and the contrast between the intense white foam and blue sky so marked, that unless considerable care was taken, colour-sensitive plates and screens would be likely to give over-correction, and render the sky unnaturally dark. They usually scored, however, when dark green rocks were included in the picture! These, under ordinary circumstances, would photograph black, but they could usually be correctly rendered with the assistance of the iso plate and screen. The plates should always be backed, owing to the violent light and shade contrasts that frequently occurred.

The Negative.

As the negatives were usually high-speed snap-shots of subjects teeming with light and atmosphere, and yet sometimes containing strong contrasts in the shape of dark rocks and white foam, development should be undertaken with considerable caution. Slow development in a very weak developer was best suited to the class of negative desired, and stand development, using a dilute adurol developer, also gave very good results. A negative full of detail, and thin, should be aimed at. This gave the rocks a chance, and it was also the right kind of negative from which to make a good enlargement.

The lecture was illustrated throughout with lantern slides which gave considerable force to the points mentioned.

THE OPTICAL CONVENTION.

THE full programme of the arrangements for the Optical Convention is now published, and will no doubt be in the hands of members by the time these lines appear. Membership of the Convention, as we have already announced, costs 5s., and applications should be addressed to the hon. secretary, Mr. F. J. Selby, M.A., Elm Lodge, Teddington, Surrey.

The following is the programme:—

Tuesday, May 30.—Opening Ceremony, Presidential Address and Conversazione, Large Hall, Northampton Institute, 8 p.m. (admission by invitation card only).

Wednesday, May 31.—Exhibition open to Members and Public, 10 a.m. to 10 p.m.

Meetings for Reading of Papers, 10 a.m. to 1 p.m.

Demonstrations, 2.30 p.m.

Thursday, June 1.—Exhibition open to Members and Public, 10 a.m. to 10 p.m.

Meetings for Reading of Papers, 10 a.m. to 1 p.m.

Historical Collection of the Royal Microscopical Society. Open to Members, 2 p.m. to 5 p.m.

Lecture by Prof. Silvanus P. Thompson, B.A., D.Sc., F.R.S., on "The Polarisation of Light by Nicol Prism and their modern Equivalents," at 8 p.m. (Members and Invited Guests only).

Friday, June 2.—Exhibition open.

Meetings for Reading of Papers, 10 a.m. to 1 p.m.

Meeting of Members.

Demonstrations, 2.30 p.m.

Business Meeting of Members, 3 p.m.

Dinner of the Optical Society.

Saturday, June 3.—Exhibition open.

Meeting for Reading of Papers.

Laboratories of University College, Gower Street, open to Members, 11 a.m. to 1 p.m.

Excursion to National Physical Laboratory in the afternoon, by kind invitation of the President.

The papers to be read make a long list, but we name those of most interest in photographic optics:—

Wednesday (10 a.m.).—Discussion on Aberrations. Papers by Dr. W. Drysdale and Mr. S. D. Chalmers, M.A.

Thursday, Section I.—Polishing of Glass Surfaces, by Lord Rayleigh. Section II.—Stereoscopic Vision, by Mr. C. S. Crawley.

Friday, Section I.—Early History of Tele-photography. Major General Waterhouse, I.A. Section II.—Tricolour Photography. Mr. A. J. Bull.

Saturday.—Some Directions of Progress in Optical Glass. Mr. W. Rosenhain, B.A.

The Northampton Institute, where the Convention is held, is easily reached from all parts of London, as it is but a few yards from the "Angel" Station of the City and South London Electric Railway, and situated near to several bus routes.

Photo-Mechanical Notes.

Three-colour Direct on Dry Plates.

Now the hot weather is approaching, and collodion emulsion begins therefore to give more trouble, it is worth while looking into the possibilities of bathed dry plates. Of the recent new sensitizers, Homocol appears to be one of the cleanest in working. Almost any plate can be bathed in this; but for direct work, to give a good dot, with short exposures, we have found Ilford "half-tone" particularly suitable. These can be bathed in the following solution:—

Homocol (1-1000 alcoholic solution)	4 parts.
Ammonia, .880	3 parts.
Distilled water	200 parts.

The plates should be bathed for two or three minutes, washed for three minutes, wiped over with cotton wool, and then put to dry in a dark cupboard. After washing, plates can be bathed in methylated spirit (old form) if they are wanted to be quickly dried. Screen distance may be about the same as for collodion emulsion, and exposures with good arc lamps, even through the red filter, ought not to run into more than ten minutes. An unbathed plate, of course, may be used for the blue filter.

Flashing in Three-colour.

In making screen negatives direct on collodion emulsion or dry plates for three-colour work, it is found necessary to flash—that is, to expose on to white paper in order to get a fine dot in the shadows. If this flashing is done through the filter, it is needless to say that the exposure must be long; but there is no necessity for this if there is some provision made to remove the colour filter while the flashing exposure is given. Then recap the lens when the filter is replaced for the exposure on the subject proper. It cannot possibly make any difference to the colour rendering to expose on white paper without the filter being in position; and, in the experience of the writer, it has made no difference whatever in the sharpness of the result, while the flashing exposure has been reduced in some cases from three minutes to ten seconds.

Removing Enamel from Etched Plates.

"Process Work," in the course of publishing queries, answered and unanswered, on various photo-mechanical topics, gives a number of replies from its readers for and against removing the enamel from etched plates, one or two of which run as follows:—

"It all depends on circumstances whether it is necessary to remove the enamel or not. In cases where burnishing is necessary it is better to remove the enamel. Also, when the plate is scratched on the surface it comes away with the enamel, and no perceptible mark is left on the bare metal. By leaving the enamel on you raise the

surface of the dot further from the base of the plate, thus making the plate really deeper by the extra thickness. In cases where a fine tint has been etched the enamel gives support to the roller, and obviates the tendency to 'dip.' The enamel may easily be removed by making the plate very hot, and brushing with a stiff brush, and a solution of caustic soda or ordinary potash. I find a solution of 1 lb. to 1½ gallons of water in either case very effective."

"One lb. of black ash or potash dissolved in 1 quart of boiling water will remove the hardest enamel. The method of employing it is to place the etched plate on a hot plate, and with a scrubbing or stiff brush scrub the potash solution on the plate until all the enamel is removed. Then wash under the water tap and dry the plate. When thoroughly dry rub the face of the plate with whiting, using a piece of india-rubber as the medium. By this means you will burnish the face and give it a good colour. As regards the removal of the enamel, some printers prefer the enamel removed, as they say that when the enamel begins to wear off it causes the ink to take unevenly, but the majority don't mind whether it is on or off. Most etching firms leave it on."

"There is absolutely no reason for taking the enamel off etched plates. Printers, as a rule, prefer to have the enamel on, as it will stand a considerable amount of pulls before wearing off, thereby giving longer life to the block. Again, some of the clients of process firms think that because the block has a good, bright enamel on, it must necessarily be a good block, because of its good appearance and finish. But should the enamel be weak and partly come off before the plate is finished, it will all have to be taken off and rolled up for fine etching. If it be a copper half-tone plate, it is best to place it in a dish of warm cyanide of potassium solution. But if a zinc plate, the best will be hot potash solution, wherein the enamel will easily wipe off with a brush."

Exhibitions.

PLYMOUTH.

THE Plymouth Photographic Society's exhibition was opened on Wednesday, May 10, and was continued also on Thursday and Friday, the 11th and 12th respectively, in the fine gallery of the Plymouth Institution, the Athenæum, which is the headquarters of the society.

The exhibition was formally opened by the Mayor of Plymouth, Mr. R. W. Winnicott, and is one which does the society credit. The general average of quality must have made the adjudication somewhat difficult. The judges were Captain J. S. Hawker; Mr. J. T. Fouracre, and Mr. J. D. Pode. In Class A, landscape, etc., the first award (bronze plaque) goes to "Tropical Vegetation," by Albert E. Coleman. This is a striking rather than a pictorial scene, in which the play of light is a feature. Second position (bronze plaque) is secured by a very fine piece of work—"Qui Vive," A. B. Fellowes-Prynn. This is a fine snap, at the happy moment, of two sharp, keen terriers upon a wet shore. Third place (hon. mention) goes to "Sunny Day at Lynmouth," by Frederick Johnson. Excellent technique and good in colour. Among other works in this class, reference may be made to the following:—"By Still Waters," C. H. Dymond; "Clovelly," by Wilfred Grist; "With the Tide," Wm. Clayden; "Sunshine and Shadow," by Fredk. Johnson; "A Summer Squall," by A. E. Coleman; "Evening in Harbour," by E. V. Hearn; "The Restless Sea," J. Trouern Trend.

Class B, portraiture, still life, etc., is a highly creditable one, both in point of numbers and in variety and quality. The first place (bronze plaque) is secured by "Afternoon Tea," by A. E. Coleman. This is a group of female mill workers, who are sitting and standing at

a table. There is, in the majority of cases, a freedom from posing, and the general effect is pleasing. No second award is given. The third place (hon. mention) being secured by "An Old Retainer," A. B. Fellowes-Pryne. This is a portrait study, treated in a quite unconventional way, with, perhaps, just a trifle too great strength in the surroundings; but the technical quality is very good. It is a pity that C. H. Dymond's "An Eastern Street Scene," evidently a Moroccan study, is so blurred in focus and so deeply printed. In the matter of composition the picture is a striking one. "Invocation," a figure study by the same worker, is a fine bit of work, very natural in pose and of the best technique. His "Study of Still Life" shows his versatility and his skill, for it is very successful, both in composition and photographically. "An Interesting Operation," A. E. Coleman, is a good study of children. "A Man of the Sea," by the same contributor, is a fine face and head study, of very good quality. Wm. Clayden's "A Breezy Day," is a soft, delightfully cool study of a seashore. The same worker's "A Study," a row of very juvenile puppies, is quaint and droll, and of much merit.

Class C, architecture, while not striking, shows distinct advance, most of the subjects being treated in a broad pictorial spirit. First place (bronze plaque) is secured by "Norman Doorway, Kilpeck," by E. G. Turney. Third place (hon. mention) goes to "South Choir Aisle, Winchester," by W. H. Mayne, a fine subject well handled, but not nearly so clever nor so difficult as his "Belfry, St. Germans." His "Sunbeams, the Nave, York Minster," is equally striking. A fine rendering of a church door is "St. Breage," by J. Trouern Trend, the rugged softness of which is admirably brought out. In "West Door, St. German's Church," C. H. Dymond has shown restraint and originality; and "The Great Hall, Haddon Hall," and "Christchurch Priory," by Frederick Johnson, are admirable examples of delicate photography.

Class D, lantern slides.—This proves to be a very excellent class, both in the matter of subject and technique. The first place (silver bowl), presented by Mr. J. Kinton Bond, M.A.) is secured by Frederick Johnson; second (Vice-President's bronze plaque, presented by Mr. F. Blanchard), by Wm. Clayden; Society's bronze plaque, by W. Anning; and third (hon. mention) by J. T. Johnson.

Class E, any subject, for those who have not before exhibited.—A small class, in which the judges have not given more than one award (bronze plaque), which has gone to "The Lilac Sun-Bonnet," Norton W. Carey, a figure study, in which, by the way, the bonnet is not more pronounced than the old lady's apron, and perhaps both are rather too pronounced.

Class F, any subject, for exhibitors not having before received an award.—The first place (bronze plaque) is secured by "The Rule of Three Doth Puzzle Me," by Stanley Sowton. The second award (bronze plaque) goes to "A Cottage well Thatched with Straw," by W. Anning.

Class G, photography applied decoratively.—This evoked but a mild response: postcards, a fire screen, and a cushion by C. H. Dymond; an overmantle in fretwork, two photographs occupying panels, by J. T. Johnson; and process blocks, with very fine postcards printed by, and the negatives produced by, J. Trouern Trend, who very properly secures a first award (bronze plaque), the only one given in the class.

For the competitor who showed not less than six prints in the first three classes the President of the Society (Mr. J. T. Johnson) offered a special silver plaque, which was won by Mr. Fredk. Johnson. Mr. H. S. Hill, Vice-President, offered a special bronze plaque, which was secured by Mr. A. B. Fellowes-Pryne.

On Friday evening a conversazione was held, at which there was a large gathering of members of the society and their friends. Altogether, the exhibition is one upon which all concerned can be congratulated.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

The following applications for patents were made between May and 6:—

DEVELOPMENT.—No. 9,116. Improvements in developing and finishing photographic plates or films and in photographic developers for use therein. C. D. Abel, Birkbeck Bank Chambers, Southampton Buildings, Chancery Lane, London, for the Actien Gesellschaft für Anilin Fabrikation, Germany.

TRIPODS.—No. 9,124. A device for holding photographic cameras upon their stands or tripods. Montague Curtis Rock, 306, High Holborn, London.

FILMS.—No. 9,246. Improvements in photographic plates and films. The Sandell Films and Plates, Limited, and Leonard Smith, 53, Chancery Lane, London.

DEVELOPMENT, ETC.—No. 9,248. Improvements in the methods of applying chemical solutions to photographic plates. Douglas William Hart, 17, McDowall Road, Camberwell, London.

TRIPOD.—No. 9,295. An improved walking-stick camera tripod. William Henry Tomkinson and Alec. J. Jones, 81, Dale Street, Liverpool.

CHANGING FILMS.—No. 9,323. A method of packing and changing sensitised films, and apparatus therefor. Jules Carpentier, Birkbeck Bank Chambers, Southampton Buildings, Chancery Lane, London.

PIGMENT PROCESS.—No. 9,324. Improvements in sensitising layers of gelatine, gum, and the like for the pigment and like photographic processes. C. D. Abel, Birkbeck Bank Buildings, Chancery Lane, London, for the Actien Gesellschaft für Anilin Fabrikation, Germany.

SHUTTER RELEASE.—No. 9,363. An electro-magnetic release for photographic shutters. Francis Noel Gasquoine, St. Oswalds, Upper Bangor, North Wales.

CINEMATOGRAPH.—No. 9,406. Improvements in apparatus relating to animated pictures. George Frederic Rayner, 37, Chancery Lane, London.

CHANGING FILMS.—No. 9,440. Improvements in apparatus for packing and changing sensitive films. Jules Carpentier, Birkbeck Bank Chambers, Southampton Buildings, Chancery Lane, London.

COLOURED PHOTOGRAPHS.—No. 9,449. Improvements in and relating to apparatus for the production and exhibition of coloured photographs. Charles Julius Drac, 18, Buckingham Street, Strand, London.

COLOUR CINEMATOGRAPHY.—No. 9,465. Improvements in or relating to cinematographic apparatus for producing natural colour records. William Friese-Greene, 20, Middle Street, Brighton.

TONING WITHOUT GOLD.—No. 9,497. Improvements relating to the rapid production of photographs on silver chloride paper without the use of gold. Herbert John Mallabar, 59, Deane Road, Liverpool.

DEVELOPER.—No. 9,537. Manufacture of a new compound of the aromatic series and of a photographic developer consisting of, or containing, this compound. C. D. Abel, Birkbeck Bank Chambers, Southampton Buildings, Chancery Lane, London, for the Actien Gesellschaft für Anilin Fabrikation, Germany.

COMPLETE SPECIFICATIONS ACCEPTED.

Specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

STORING NEGATIVES.—No. 20,114, 1904. The device for which pro-

tection is claimed is a box of rectangular form (the lid of which forms a part of the total depth when closed) to hold a series of negatives enclosed in consecutively numbered envelopes and an index card. The former, which may be of paper or any other suitable material, are provided with tabs intended to receive reference numbers; these tabs are not folded down, but stand erect, thereby allowing of convenient manipulation when looking out a negative. A ruled and numbered index card, preferably folded, is provided, for the purpose of receiving the titles of the subjects of negatives contained in the respective envelopes, and is of similar shape and dimensions to the latter. To prevent the lid from fouling the tabs of envelopes when the box is closed, clearance blocks are fixed at the inside corners or ends of the box, which keep the tabs clear of the joint. A rebated recess may be formed in the front of box to receive a card or tablet to indicate the series of the contained negatives, or the recess may be large enough to accommodate the index card (which, in this case, would not be folded) and a cover glass for the purpose of keeping it clean. Houghtons Limited, 88 and 89, High Holborn, W.C., and Alfred Sidney Spratt, 207, Evering Road, Clapton, N.E.

New Materials.

Photo-Medallions: a Side-line for Professional Photographers. Made by Dorrett and Martin, 60, Strand, London, W.C.

Some pleasing and attractive form of portrait which can be shown to a client at the time of the sitting or when proofs are examined would be sure of attention from the professional photographer. True, there has been no lack of such novelties in the past, but fashions alter,

"satin," these different effects being obtained by the celluloid, not by the print. The "glossy" resembles a ceramic enamel; the "matt" has the delicate effect of ivory or opal; and the "satin" imitates the texture of that material, and presents a very rich appearance. Let us repeat—these effects are in the celluloid, and the medallions can be washed with water whenever they become soiled. These three varieties can be coloured for small sums, and they further lend themselves to endless forms of mounting, a few of which are here illustrated. The most attractive, in our judgment, are the cases, leather and satin lined, which are made to take one or more medallions of circular or oval shape. The prices of these impress us as extremely moderate. As an example, the undiscounted figure for a cabinet circle in the best quality case is 8s. Circular wood frames in various mouldings and colours supply a cheaper mounting, and the medallions are also obtainable with a wire strut only for their support. Messrs. Dorrett and Martin's list gives the detailed prices for these, and no photographer should regret an hour spent in studying its contents. He should find in it the way to new business.

Ilford "Carbon Surface" P.O.P. Manufactured by Ilford, Limited, Ilford, E.

In introducing a new variety of their old-established P.O.P. the Ilford Company are evidently responding to the demands of the large class of both professional and amateur photographers who favour, for different reasons, a print of "broader" surface than that of the matt printing-out paper. The effect of carbon is a desideratum in the eyes of a photographer in business to meet the wants of a clientèle more cultured than the average, and the attainment of this effect without varying the methods of the printing-room is surely a matter of importance to those who produce their work from first to last on their own premises. The Ilford "Carbon Surface" paper yields prints

Some Styles of Mounted Photo-Medallions.

and it behoves the manager of a studio constantly to have something fresh to put before his people as a temptation to them to enlarge their original order. Of such temptations, a new series of photo-medallions by Messrs. Dorrett and Martin commands our emphatic approval for the effect and variety of the styles as much as for the reasonable prices at which they are offered. Many of these are put in figures which make us wonder how the work can pay. However, that is the firm's business; ours is to explain briefly the nature of the medallions. They consist of a print—which may be P.O.P., bromide, carbon, or platinotype, and supplied by the photographer if desired—mounted, photo-button fashion, behind celluloid. Let it not be thought that the appearance of the medallion recalls the other cheap finish of the photo-button as usually manufactured. The medallions are turned out in three styles, "glossy," "matt," and

of close resemblance to the customary carbon print, and the manipulation is no wise departs from that of the ordinary matt P.O.P., save, perhaps, that there is a slight difference in the extent to which printing is done. Our own experience of the paper is necessarily brief, but in all other respects we could detect no difference between its behaviour and that of the regular brands of Ilford P.O.P. The new paper should therefore be acceptable to the profession, which should welcome it as affording a new style in portraits, and that of a handsome and striking character.

Heliotrope "Professional" P.O.P. Manufactured by John J. Griffin and Sons, Limited, 20-26, Sardinia Street, London, W.C.

Messrs. Griffin prepare a gelatine printing-out paper specially for the profession and its qualities of soft contrast in printing, quick

toning, and hard surface no doubt recommend it to printers in many establishments. The present new issue is warm mauve in colour, and if we may speak from our experience of it, ought to prove generally acceptable. The tint is distinctly deeper than that of the "mauve" of the same make; yet there is not too much of it, and it will be found that a faint hue of this kind often has no more effect than to overcome the suggestion of colour in the higher lights. As many photographers know, a bluish tint produces the impression of brilliant whites in these parts of the subject. In manipulation and price Messrs. Griffin's new paper is precisely similar to the ordinary mauve-tinted paper.

SEVERAL patterns of dark-room lamps, specially fitted with the new gelatoid screens of Dr. Meithe, are now being introduced by Messrs. A. E. Staley and Co., the sole agents for the screens. The lamps are designed for gas, oil, and electric light, and cost from 12s. 6d. to 21s. Messrs. Staley will send full particulars on application to 19, Thavies Inn, Holborn Circus, London, E.C.

New Books.

"The Practical Photographers' Annual," 1905. London: Hodder and Stoughton. 1s. 6d.

A writer, even a writer on technics, must sometimes be unable to suppress a legitimate curiosity as to who are his readers. We must own some desire to see the manner of practical photographer who derives assistance from this "concise and practical dictionary of the photographer's daily practice," compiled with obvious industry by the Rev. F. C. Lambert, M.A. We can imagine a thoroughly practical photographer who finds himself at no disadvantage because he does not know how to make a cork-squeezer from a hatchet-shaped piece of wood (p. 26), and though any expedient should be welcomed in the extremity of finding oneself out with the camera *minus* its lens, we hardly endorse the advice to "cut a piece of thin card and fit this in the flange hole. Then pierce the centre with a pin or needle and make a pinhole negative." There may be people who will benefit by these hints, but we cannot help wondering what sort of photographers they are. A practical photographer would probably have found other occupancy for the space taken by such paragraphs as:—"If you break off the neck of a white glass round bottle of some such shape as that in the annexed figure, do not throw it away, because it is quite an easy matter to cut it down and make a vessel which is useful for various purposes."

"*Signs of Rain*.—Clearness of the air. Distant objects look larger or nearer than usual. Distant sounds heard more clearly and louder than usual. Creaking of furniture. Fire burns dull and dim. Snails come out. Dogs are sleepy. Cats are frisky. Sheep huddle together in the field. Cattle are lowing in the stalls. Swallows fly low over the water. Plants close their petals (chickweed, scarlet pimpernel)."

"No focussing cloth! Borrow a friend's coat, or use a half-open umbrella."

The last extract puzzles us. Why should the photographer not use his own coat, or has he forgotten that as well? However, nobody will grumble at paying eighteen pence for the book, which is ornamented with a piece of Mr. Furley Lewis's clever portraiture—subject, the Editor in an attitude which for any purpose but the frontispiece to a "practical dictionary" we should consider happy in the extreme.

A POPULAR guide to the Continent is just published at sixpence for the use of travellers by the extensive routes of the Great Eastern Railway Company to the Tyrol, North Germany, Norway, Sweden, and Switzerland. It is published at 30, Fleet Street, London, E.C.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

May.	Name of Society.	Subject.
23.....	Royal Photographic Society ...	<i>Röntgen Rays in Medical Work.</i> Dr. Thurstan Holland, F.R.P.S.
23.....	Manchester Amateur Ph. Soc.	<i>Platinotype Printing.</i> Mr. T. L. Cooper.

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

A MEETING of the General Committee was held at 51, Baker Street, W., on Friday, the 12th inst. Present: Messrs. A. C. Banfield, E. C. Elliott, M. Jacolette, A. Mackie, D. Prodger, E. Scamell, R. Fellows Willson, William Grove, H. A. Chapman (Swansea), and P. Lankester (Tunbridge Wells). Mr. Martin Jacolette (vice-president) presided. After the routine business had been transacted, a further discussion took place on the proposal to associate certificated assistants, and it was finally decided, subject to confirmation at the next committee meeting, to recommend to the next annual general meeting for embodiment in the rules, that certificated assistants be granted all the privileges of the Association, except that of voting, subject to the payment of a registration fee annually.

The issue of a quarterly circular to members was again discussed, and, after several suggestions had been made, the matter was adjourned until the next meeting, when it would be finally settled.

The Chairman drew attention to the fact that the professional photographers of New York has just organised a similar association to the P.P.A., and that, according to the report of the foundation meeting, the questions that the New York Association proposed to deal with were exactly those which this association had been dealing with. The question of insurance rates, the difficulties of copyright, and something like the certificate scheme had been referred to as matters for attention. He proposed, and it was cordially adopted, that the hon. secretary be desired to convey to the president of the New York Association congratulations on the successful establishment of their institution and best wishes for its prosperity.

ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held May 16, Mr. J. C. S. Mummery in the chair. An illustrated lecture on "Marine Photography" was given by Mr. F. J. Mortimer, F.R.P.S. An abstract of the lecture is given on another page. The house exhibition of marine photographs and wave studies by this worker was also opened to the public on the same evening. A detailed report of the pictures will be given in our next issue.

LONDON AND PROVINCIAL.—Meeting held April 11, Mr. Rapson in the chair. Mr. E. R. Human read a paper on "Combination Printing," in which he described a method of printing clouds into landscape negatives, preferable, in his experience, to the usual one of masking landscape and cloud negative, when printing, separately, from these negatives. Assuming, then, that the negatives are ready for printing, a twelve by ten frame is taken for a whole-plate negative, a sheet of good, clear, white glass placed in it, and the landscape negative upon this, so that about one to one and a half inches are caught by the hinged back to prevent any movement during examination. A ten by eight frame may be used for half-plates, and a whole-plate one for quarter plates. If addition is to be made to the length of the sky, a sheet of black, opaque paper is placed at the sky end of the negative to protect the paper from becoming degraded, the printing paper is then put into place, and the frame turned over. A sheet of cardboard is then placed in front, with the edge turned

wards, and the frame put out to print in a diffused light. When efficiently printed, the operation is reversed, the sky negative taking the place of the landscape, and the printing done as before. The effect of this procedure is that the two printings are so vignettted one into the other that it is impossible for anyone to detect that double printing has been done. This was described fully by Mr. Human, the whole being illustrated by a blackboard sketch, which greatly assisted those present in following the remarks. For all papers with a visible semi-visible image, this plan was followed. For carbon work a slip of paper was fastened to the edge of the frame, and marks made thereon, to give the position of the vignettes. In printing bromide, other papers of that description, the same marks as for carbon were used, and a sheet of cardboard kept on the move for about one and a half inches to and fro. Clouds in lantern slides were put in by first taking the slide and then using this as a mask for the cover glass, either in the printing frame or slide, as the case might be. In enlarging, a sheet of cardboard was kept on the move, as in contact bromide printing, between the lens and the easel. To introduce figures into landscapes, the figure negative was first blocked out, and a positive made on a slow film, or on carbon tissue, the effect being a positive of the figure with a clear background. Next a print of the figure was carefully cut round and put into place upon the background negative, and a positive of this taken, thus giving a clear space the size of the figure. The two positives were then bound together, and a direct enlarged negative made, when all was plain printing, and any number of prints were obtained exactly alike. Prints were passed and done by the method, one being from three negatives, having a background worked in, and in no cases could the joint be detected. A discussion took place, Mr. Teape saying that he, for one, had learned something, as, although he had for many purposes used the bent edge, he had never thought of it in conjunction with the class of print under discussion. Mr. Freshwater asked, with regard to the print in three negatives, which one the boat was in, and Mr. Human replied that it was in the centre one. Mr. Haddon asked if, when printing in P.O.P. papers, Mr. Human had not found a difference of colour in the sky and the landscape, due to the different density of the negative, and Mr. Human replied that that was so, explaining that he very seldom used this class of paper except for rough proofs. A hearty vote of thanks to Mr. Human brought the meeting to a close.

HEFFIELD AND HALLAMSHIRE PHOTOGRAPHIC SOCIETY.—An instructive evening was passed by the members of this society at their usual monthly meeting last week at Cemetery Road Baptist Schools, when H. G. Paterson gave a demonstration on the æsthetic style of "mounting prints" so much in vogue at various exhibitions. During the course of the demonstration Dr. Paterson showed how the eye could be deceived in mounting prints of equal size on different size mounts, and also illustrated how, by various widths of margin and positions of prints, to get the best results from both vertical and horizontal prints.

NORTHAMPTON PHOTOGRAPHIC SOCIETY.—The adjourned annual meeting of the Photographic Section of the Northampton Natural History Society was held at the Society's Rooms, Sheep Street, on Friday evening last. The question of how best to deal with the deficiency of £10 reported at the last meeting again came before the society. It was decided to apply to the parent society for a portion of the amount required to liquidate the deficiency, and the president undertook to secure the balance by private subscription. A suggestion put forward that the Photographic Section should be merged with the Archeological Section in some of their excursions was received with approval; but the excursions of the Photographic Section are still to be arranged.

LOUGHBOROUGH PHOTOGRAPHIC SOCIETY.—The annual meeting of

this society was held at the Temperance Hall, Loughborough, on Friday evening last. The report, presented by the hon. secretary, Mr. Herbert W. Cook, recorded a year of useful and interesting photographic work, and there was a balance in hand. Officers and committee were elected for the ensuing year, and the medals won at the members' exhibition were presented.

HUNTINGDON AMATEUR PHOTOGRAPHIC SOCIETY.—The annual meeting of this society was held at the Volunteer Drill Hall on Wednesday last. The accounts showed a balance in hand, and the secretary said that endeavours had been made to secure a permanent "home" for the society, and on the application of Sergeant-Major Page, Colonel Linton has consented to allow the society to use the Drill Hall free of all charge. The election of officers resulted as follows:—President, Mr. W. C. Bernard; vice-presidents, Revs. Hedley Vicars, G. S. Morley, and G. R. Holt Shafto, Messrs. F. B. Thackray, J. W. Tysoe, A. G. Dille; hon secretary, Mr. E. Trench Smith; treasurer, Mr. H. Goggs; committee, Messrs. J. Pascoe, W. D. Storey, W. Murton, Allen, Hawson, and Sergeant-Major Page.

HULL PHOTOGRAPHIC SOCIETY.—The excursion of this society to Little Weighton and Risby Park last week proved a great success from the pictorial standpoint.

BOROUGH POLYTECHNIC PHOTOGRAPHIC SOCIETY.—On May 3 Mr. Thomas Manly delivered an interesting lecture on the "Ozotype" process to the members of this society.

THANET PHOTOGRAPHIC SOCIETY.—An extraordinary general meeting in this Society was held at the Club-room, on Wednesday of last week, when the rules as amended by the committee came up for consideration. It was decided to raise the subscription from 2s. 6d. to 5s., with an entrance fee of 2s., ladies and youths under eighteen years of age being admitted upon payment of a subscription of 2s. 6d. It was stated that the object of increasing the subscription was to provide better club-room accommodation, and a dark-room and enlarging apparatus. Attention was called to the fact that the meetings of the society were held alternately at Ramsgate and Margate, but as the majority of the members belonged to the former town it was thought that the meetings at Ramsgate should be held more frequently, and it was decided to insert a rule to the effect that the headquarters of the society should be in that town.

RICHMOND CAMERA CLUB.—The fifteenth annual report of this club shows that a most successful season has been passed. The lectures have been well attended, and the interest of the members well sustained. The financial position of the club remains satisfactory, there being a cash balance of £27 3s. 8d., with a small outstanding liability.

WATFORD CAMERA CLUB.—"Flower Photography" was the title of an instructive lecture given by Mr. E. Seymour, before the members of this club, on Thursday of last week.

SOCIETY OF ARTS AND LONDON INSTITUTION.—We have been informed that by a resolution passed by the Council of the Society of Arts at their meeting held on May 8 it was decided that "In view of the feeling which appears to have been aroused amongst some of the proprietors of the London Institution with regard to the proposed amalgamation with the Society of Arts, and the consequent probable difficulties of effecting a harmonious fusion of the two corporations into a single institution, the Council of the Society of Arts have decided not to take any further action in the matter, and hereby discharge the committee which, at the instance of the Board of Managers of the London Institution, they appointed to consider the scheme for amalgamation."

Commercial & Legal Intelligence

FALSE PRETENCES.—At Ludlow, last week, William H. Nicholls, a photographer, was sent to gaol for three months for obtaining 3s. 6d. by false pretences from Albert John Windle, schoolmaster, Richard's Castle. The evidence showed that prisoner called on prosecutor soliciting orders for enlargement of photographs. Prosecutor agreed to have a photo enlarged, and paid prisoner 3s. 6d. Since that day he had not seen prisoner, neither had he had his photograph.

THEFTS BY PLYMOUTH PHOTOGRAPHERS.—Alexander McGillivray and Edward Thomas, both photographers, were charged at Plymouth during last week with stealing within the past six months four dozen bromide prints and five dozen mounts, valued at 5s., the property of James Hawke, 8, George Street. McGillivray had been in Mr. Hawke's employ 14 or 15 years, and was the chief silver printer, and Thomas, who had been employed at the establishment 10 or 11 years, was the chief of the bromide printing department. In consequence of information received, Mr. Hawke found that a negative taken by himself some years ago of a lady had been obtained possession of by McGillivray, who had arranged with the person who desired to have the photograph of that lady to print five dozen bromide copies from it. McGillivray obtained from Mr. Hawke's establishment the necessary papers through Thomas. Five dozen mounts, bearing Mr. Hawke's name, were also obtained. Mr. Hawke had no desire to be vindictive, or have the men unduly punished; he was anxious to prevent a repetition of the offence. Each defendant was fined £3 or three months.

ALLEGED FALSE PRETENCES CASE.—Thomas Houston, of 274, Burnley Road, Newchurch, was charged under a warrant with obtaining, by means of false pretences, 10s. from James Sharples. Mr. T. R. Bertwistle, for the prosecution, said that in January the prisoner called upon Mr. Sharples, of the White Boar, Prince's Street, and took an order from him for three dozen cabinet photographs to be taken from an oil painting of Mr. Sharples's late wife. Sharples paid 10s., and got a receipt. On January 19 the prisoner called again and got 5s. Sharples heard nothing for a long time, and he went to the address given on the card, that of Cecil Bradshaw, and was told that the man was a fraud; he could not take any order from him. Mr. Sharples could neither get his oil painting back nor his money, and he took the trouble to go to Newchurch, where the prisoner lived, and could get no satisfaction. Mr. Bradshaw now said that on and off this man had been his agent. The order had now been executed, so that he could not see how they could say the prisoner was guilty. He, however, wanted to clear Mr. Sharples. James Sharples said that Bradshaw told him that the prisoner brought him an order now and again, but he was not an agent. Mr. Bertwistle said he did not think there was sufficient evidence to convict. The prisoner.—So that I cannot take an action against him, is that it?—You can take whatever action you think fit. The prisoner was discharged.

A RECEIVING ORDER IN BANKRUPTCY has been made against Mrs. Kathleen Ada Macdonald, carrying on business at High Street, Eton, as a photographer.

COLOUR OF EASTBOURNE SAND.—The colouring of picture postcards was discussed before Mr. Justice Wills last Thursday, when Messrs. Petty and Sons, of Reading, sued the Photographic Tourist Association for £198 5s. for picture postcards delivered. The defendants, who complained about the colouring and quality of the cards, entered a counter-claim for loss of profits. Mr. Oustlewaite, a dealer, said that the view of Eastbourne Parade was not equal to the sample, and complained about the colour of the sand, which, he said, looked muddy and dirty. Mr. Powell, K.C., suggested that

"perhaps the photograph was taken after Bank Holiday." The jury gave their verdict for defendant. Costs followed the verdict, and it was agreed to pay plaintiff £5 for such cards as had been sold.

ENLARGED PHOTOGRAPHS.—At the Clerkenwell County Court, on May 11, Francis Kotch, photographer, of 75, Essex Road, Islington, sued the British Art Company, photographic enlargers, 61, Essex Road, for £4 10s. 6d. in respect of goods detained and damages. Plaintiff said that on December 12 last one of his customers had a photograph taken, and, as he required an enlargement of the same, it was sent to defendants, who made the enlargement. The customer was so pleased with it that he ordered a second one. This was also entrusted to defendants for execution, but the second enlargement did not give the customer satisfaction. Defendants undertook to make a further one, and were supplied with the first enlargement, as well as the negative. Defendants kept them for two months, and, as a result, he had to return the money to his customer. The defence was that no mention was made of the second order being a repeat one. Nothing was said about a special size of the head being required, or it would have been attended to. They voluntarily offered to make a third one, but before this could be completed a question arose as to a previous account with plaintiff for work done, and they declined to give up the goods as they had a lien on them. The Judge found in favour of defendants.

EMBEZZLEMENT AT NORTH SHIELDS.—James C. Murray, a bio-photoscope operator belonging to Hull, was charged, at North Shields, on Monday last, with having embezzled and stolen £3 5s., the money of Walter Payne, his employer, on March 4. Accused pleaded not guilty. He was committed for trial at the Quarter Sessions. Before the court rose, however, he pleaded guilty, and was committed to prison for one month in the second division.

A ROUNDABOUT PROCEEDING.—At Newport (Mon.) County Court on Friday last, before Judge Owen, a man named Seidle appeared to answer a judgment summons obtained against him by a firm of photographic dealers, of Newcastle. The amount owing was £6 14s. 9d. The Judge remarked that the plaintiff lived at Newcastle-on-Tyne, the defendant lived at Newport, and judgment against him was obtained in Birmingham, and thought it a very curious proceeding. An order for £1 a month was made.

THE following contribution reaches us from a correspondent in Paisley, who tells us he has been a reader for between thirty and forty years:—

Thanks for your copy of the famed "B.J.";
Its weekly numbers are a charm to me,
My solace, guide, and friend for forty years,
Where all that's useful in our art appears
In literary form, or brief chit chat,
Or even "Answers," it is good at that.
'Tis very gentle to the young beginner,
Whose questions oft would bore a saint or sinner;
To ready writers it gives ample scope
To air a grievance, or to fan a hope.
Why! even I have used it in my time
To tell of something both in prose and rhyme.
Go! golden photographic gospel go
And spread the news photographers should know.

THE "Globe" learns that 'The two-year-old son of a photographer having been photographed by different members of the family over 200 times, the N.S.P.C.C. is taking the case up vigorously.'

ILLEGAL Giant Postcard.—A stationer at Southport recently erected in a prominent position a sign consisting of an enlarged facsimile of a postcard, drawing attention to the address of his shop. The trades man has now been notified by the Postmaster-General that he must either remove the sign or obliterate the representation of the King's head. It was pointed out that under Section 7 of the Post Office Protection Act the representation of a postage stamp for advertising purposes is contrary to the Act.

ADVERTISE—TO WHOM?

To the Editors.

Gentlemen,—I read in a novel this week: "Marcia was not feminine in her arrangements of a room; there were no fripperies, and few photographs." The sentence implies a truth which we as photographers ought to realise with all possible clearness—it is Her Royal Highness Woman who keeps us going. That essential fact seems to have been ignored in very large measure by the writers on advertising who have recently done good service in your pages. Why did they not single out woman as the great and predominant customer of the photographer? A woman comes herself to be photographed; she brings her children to be photographed; coerced or cajoled by her, men crucify their natural instincts, and visit the photographer's studio. There is only one person, Sirs, to whom the photographer need offer his wares. I read that Pirie MacDonald, the New York photographer of MEN ONLY, advertises to the ladies only. He knows the way of the world, and my professional brethren must learn the way in order to draw the clients to the studios. I have answered my question—to whom? There remains the second and more complex problem—How? That must depend upon circumstances. Your farmer's homely spouse is not induced by the bait which is taken at a gulp by Macame Brixton. Sufficient for me to point out a factor in a photographer's advertising which, in my experience, is of the highest importance.—I am, gentlemen, yours faithfully.

SQUIRE O' DAMES.

MAKERS' FORMULÆ.

To the Editors.

Gentlemen,—I have been much interested in the correspondence that has appeared in your columns under the above heading, but I must confess that there is still some ambiguity left in my mind.

There are one or two points not touched upon in any of the letters to which I crave permission to draw attention. For instance, we are frequently told to take equal quantities of A and B and add an equal quantity of water. What I should like to know is whether the amount of water should be equal in quantity to A and B, or to A plus B?

Again, we have such directions as: "Mix equal parts of A and B and from 2 to 3 times the quantity of water." There is here considerable room for doubt as to whether the "2 or 3 times the quantity of water" refers to the part of A or the total amount.

Then what is a "part"? Take the following typical formula:—

Hypo	4 parts.
Sulphite	1 part.
Water	20 parts.

Here there are parts in solids and parts in liquids.

It would be useful if we could have some authoritative ruling on the subject, which would help to throw a little clear light on this complicated matter.—Yours faithfully,

FRED. BELL.

Lewisham, S.E.

[This correspondence is now closed. We shall refer to the subject next week.—Ebs., B.J.P.]

PAINTINGS AT HAMPTON COURT.

To the Editors.

Gentlemen,—I notice in this week's JOURNAL a gentleman asking for picture No. 590, King's Gallery, Hampton Court. I think you

will find it is to be obtained from Mr. A. Tear, Bridge Road Studio, East Molesey, Hampton Court, as are also others in the gallery.—Yours faithfully,

RAYMOND COX.

May 12, 1905.

THE PRESS UNION.

To the Editors.

Gentlemen,—In reference to the query on above subject on p. 380 of last issue, the Institute of Journalists, Fleet Street, E.C., issues a special ticket to its members, which said ticket is generally recognised by policemen and others. Possibly your correspondent refers to this.—Yours, etc.,

MEMBER INST. JOURN.

London, E.C.

COLD STARCH PASTE.

To the Editors.

Gentlemen,—The note on cold water starch in "Foreign Notes and News" reminds me of a method of making starch paste which perhaps is unknown to many readers of the BRITISH JOURNAL, but as it is offer of service I may mention it. All you have to do is mix starch and cold water to a thin cream, and then add solution of caustic potash (stick) in small doses. This will cause the starch to jellyify, and if it is too viscous water can be stirred in to thin it down. Of course, such paste must not be used for mounting photographs, but for any job such as sticking on labels there is no quicker way of preparing a paste.—Yours truly,

C. F. CAMPBELL.

[We believe this alkaline paste is largely sold as office adhesive, but, as our correspondent points out, it is not a photographic mountant, nor is neutralisation of the alkali of any service for the adhesiveness of the mixture is thereby greatly diminished.—Ebs. B.J.P.]

QUITE a little batch of congratulatory letters chance to reach our table this week from readers whose interest in the BRITISH JOURNAL is undiminished. Mr. G. Mansfield of Naas, Ireland, writes: "I think I have been over 30 years a subscriber to your valuable journal." Mr. John Bell, of Barrhead, tells us: "I have been a subscriber to the 'British' since I was apprenticed to the business, and that will be about 23 years now." From New Zealand comes appreciation in the shape of some lines from Geo. F. Randall, Kaka Point, Clutha. "The BRITISH JOURNAL," he says, "keeps me up-to-date, as I get it about 40 days after publication, which is not bad for 16,000 miles away." Mr. T. Birtles, Warrington, boasts that he has "taken the BRITISH JOURNAL weekly for the last 35 years and over. Have you many that have been readers longer than this?"

The death is reported of Mr. Robert Stewart, of Elgin. Mr. Stewart was one of Scotland's oldest photographers, and having been born in 1813, has lived under the sovereignty of five monarchs. When photography was first introduced he took up the practice of it with enthusiasm, and lost no opportunity of making himself proficient. Forsaking the role of bookseller, he started a photographic business in Elgin. He soon proved himself a photographer of no mean merit, and the name of "Stewart, photographer, Elgin," was very generally known. Before quitting the business some years ago he trained three of his sons in the profession, and one of them—Mr. R. Stewart—still carries it on with much success.

THE R.P.S. Honorary Fellowship.—The following resolution has been passed by the Council of the Royal Photographic Society: "It is desirable that the award of the Progress Medal should be accompanied by the Honorary Fellowship." The Council have elected the following Honorary Fellows:—Major-General J. Waterhouse, I.A., Mr. W. Willis, Mr. Robert Demachy, Mr. Alfred Steiglitz.

Answers to Correspondents.

- * *All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C. Inattention to this ensures delay.*
- * *Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*
- * *Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.*
- * *For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.*

PHOTOGRAPHS REGISTERED:—

- E. O. Jones, Emporium, Talybont, Cardiganshire. *Photograph of the House where the late John Adams, Shoemaker, Talybont, lived. Photograph of Talybont Village.*
- W. T. Carter, 43, Drake Street, Rochdale. *Photograph of Rochdale Corporation Tramways. Old and New Cars.*
- J. Bell, 176, Main Street, Barrhead, N.B. *Photograph of Municipal Buildings, Barrhead, Renfrewshire.*
- E. McGeachie, The Studio, Hillfoot Street, Dunoon, N.B. *Two Photographs (Flashlight) entitled "St. Paul," taken in the Burgh Hall, Dunoon. Dunoon Grammar School Continuation Class, 1905.*
- W. Baker, Toll Street, Derby Road, Nottingham. *Photograph of Wollaton Hall, Wollaton, Nottinghamshire.*
- J. J. Wright, 125, London Road, King's Lynn. *Four Photographs of the North West Norfolk Village Choir Festival, held in Corn Exchange, King's Lynn, May 8, 1905.*
- T. V. Biggins, 257, Boulevard, Hull. *Photograph of the New School of Art, Anlaby Road, Hull.*

DUFFER.—The work you send us is useless in any but the lowest class of studio. You had better take a few lessons; they would certainly benefit you.

GEORGE S. COX.—1. All three cameras you mention are good. No. 1 has probably more movements than the others, but each can be relied upon. 2. This lens will be suitable for almost every class of work. 3. The quarter-plate size is more handy, and, with the lens you mention, negatives should be obtained capable of enlargement to any reasonable size.

REFLECTOR FOR ENLARGING.—I wish to do daylight enlarging, bromide enlargements, etc., and I want you to tell me how big my reflector for throwing light through, say, 12 by 10 negative would have to be, and which would be best for reflector, a sheet of white paper or opal glass? I have enclosed a rough sketch of situation of room, and I should like to know if I can get good results under the circumstances, because I have read that to do daylight enlarging you must have unobscured sky light, but in my case I have the back of opposite houses, but I think that a reflector would alleviate that defect.—C. R. DODD.

The reflector needs to be considerably larger than the negative. You can easily see how large by placing a piece of clear glass in the negative-carrier and observing, from the point the lens is to occupy, whether the light comes from the reflector. Clean white paper is a better reflector, but opal is preferable for permanent use. Your position should not prevent your doing good work.

TONING BROMIDES.—Would you kindly let me know the best means of obtaining sepia tones on bromide and C.C. papers? I have tried all the formulæ, but am unable to get the desired shade. I should like a formula as simple as possible. I find the complicated ones are too difficult to work.—B. W. HOY.

For bromides, bleach the prints in: Potass. ferricyanide, $\frac{1}{2}$ oz.; ammonium bromide, 300 grains; water, 20 oz.; and,

after well washing, darken in: Sodium sulphide, 30 grains water, 10 oz. There are several rapid toners of this kind on the market. For warm tones on platinotype paper, you must employ a developer with mercuric chloride in it or use the special sepia paper.

RETOUCHING.—Will you kindly pass your opinion upon my touching? You will find prints of same enclosed. I have had just twelve months' experience at the work.—RETOUCHER.

For the time your knowledge extends we consider you have made very fair progress; but you have yet much to learn. Differentiate your touch more in the treatment of men and women, and see that you do not thin the noses unduly or alter feature lines. In the oval of lady in hat, the nostril is pinched through over-removal of its formation line or shadow, and the nose itself is too pointed. The shape of same feature in the circle print is altered, being too fat just below the bridge and also flat in effect. The very nicest attention is called for about the nose, lips, and chin in every face. A wrong touch or two may alter the whole expression. The man is the best study, but here again the nose is faulty, and not as in the unretouched. When time has brought you much greater experience, we consider you will become a first-class retoucher. All prints sent for criticism of retouching should be made on glossy P.O.P., although a mixture of papers is not objected to.

RETOUCHING.—Would you kindly give your opinion of the retouching of the enclosed prints, and state where the same might be improved?—IMPROVER.

"Improver" should always sign his name to all communications; we like to know whom we are dealing with. Your work is indifferent, and offers great scope for improvement. The touch is too loose and wandering, and the effect is shabby and ragged in many places. We could have judged better if you had stated the time devoted to each negative. Give them more work, and be finer and closer in your texture. As repeated over and over again in these columns, prints sent for criticism of retouching should be toned and fixed to show all possible detail.

BLACK AND WHITE BACKGROUNDS.—Could you let me know how to make two backgrounds? I want one to photograph perfectly black, and the other perfectly white. I am told there are certain colours for these. I tried black and white, but the black did not photograph dark enough, and the white came out dirty-looking with correctly exposed negatives. I want to make them distemper on canvas.—L. SARGEANT.

Fine vegetable black mixed with some red pigment, such as sienna or Venetian red, is the best mixture you can use for a dead black ground, but you will never get a ground which reflects no light. The most perfect black ground is dark space, i.e., a darkened room draped with black, before an opening in which such as folding doors, the sitter is posed. For a brilliant white ground, the best pigment is zinc white, or the best white lead.

LENS FOR HAND CAMERA.—I have just bought a hand camera to take pictures size of enclosed. It is fitted with "achromatic lens." The result is bad, showing great distortion. Please tell me if I can have another lens fitted in exchange; if so, what sort will be best for upright results? Will a camera fitted with rapid rectilinear lens overcome the difficulty?—A. C.

It is not the fault of the lens, but of yourself in tilting the camera and holding it "out of square." Get an elementary book on hand-camera photography.

INQUIRER.—We cannot recommend agents. The only suggestion we have is that you should advertise the concern.

DAMAGED GLASS POSITIVE.—I had a photograph to copy which was taken forty years ago. It is a glass positive, and being very dusty between the cover glass and the surface of the positive, I asked my assistant to dust carefully before copying. He brought it to me a few minutes afterwards with the photograph rubbed off the part he cleaned (evidently with a duster or handkerchief). Is there any means of bringing the picture on again, as the substratum, whether albumen or collodion, is still there and undamaged? It seems to be too thin for collodion, and if breathed upon the positive shows faintly. The high-lights came off in a sort of powder as soon as rubbed. The photo was painted black on the back, and not on the film, as the ordinary wet plate positive.—OLD PHOTO.

From what is said we suspect the picture is irretrievably ruined, as the image seems to have been wiped off and there is no means of restoring it. In our issue for April 21 last there is an article on "Repairing and Copying Glass Positives." That may be of some service to our correspondent, but we fear it will not. This case illustrates how what may be a valuable picture may be completely ruined when it is entrusted to people who do not understand their business.

BROMIDE PRINTING.—1. Would you please advise me how to do a large number of bromide prints? As far as a few is concerned I am right, but I want to do some hundreds and want to fix them in large batches of, say, 60 or more. What solution ought the prints to be put in to stop development until I have the lot ready for fixing? 2. Will you please advise as to other papers that are developed? My object is to avoid all doubt as to fixation by giving the same fixing to all, as possibly if I relied on my own judgment about perfect fixing I may be mistaken here and there.—SMEATON.

1. A weak solution of citric acid will arrest development—5 grains per ounce is strong enough. We should prefer to use running water, however, as it is unwise to use acid before fixing. 2. We are not clear as to your query, but we should advise you to use a 4 ounces per pint fixing bath, and put your prints to fix in batches of twenty or so for ten minutes, giving them an occasional turn over.

RETOUCHING.—I am a beginner in retouching, and am sending to you for your kind opinion of my work. I have been practising retouching for about six months. 1. The specimens of elderly lady and gentleman were my first attempts, in which I know I have lost character, half-tone, and likeness, but I send them so that you may inform me if you consider I am improving. 2. The other two specimens (young men) are my latest work. 3. Will you also tell me if you consider with practice and patience I may eventually hope to become a good retoucher? 4. I am afraid I am rather slow at present—the last two negatives took me one hour each. 5. I find your criticisms of other retouching in the correspondence columns of the "Journal" very helpful to me, and hope your advice to me may be helpful to others. 6. I have been told by a retoucher that my work is too fine. Could you inform me how to avoid this, if it is so?—HOPEFUL.

1. Your specimens show the usual first attempt—very bad! and your own criticism is sufficient. 2. A decided improvement, certainly, but still a loss of character and modelling, and a wholesale removal of wrinkles, which even in young men are admissible if true to life. 3. You will certainly make a good retoucher in time, especially if you have a clever teacher to advise you. 4. One hour for this size is not too slow if properly done, but the finish must be higher-class for the time taken. 5. We are pleased that our columns have

afforded you such help, and hope they will continue to be of service to all young assistants in every branch. We represent the profession, and it is satisfactory to meet with appreciation. 6. At the same time we are not teachers of retouching, but critics, and it is impossible properly to advise you from a mere print. You need a skilled instructor to see a series of your efforts, and to point out your faults as you make them. Teaching yourself is slow work, and the most expensive in the long run. Correspondents should bear in mind that while we can find space for brief hints, the chief duty we have to discharge is frank criticism of the work submitted to us.

MERCURY VAPOUR LAMP.—Will you kindly give me the address of the makers of the "Cooper Hewitt Mercury Vapour Lamp," or could you inform me where I might obtain full information about this lamp?—WM. ALEXANDER.

Messrs. Penrose and Co., 109, Farringdon Road, London, E.C. A series of articles on the lamp appeared in our issues of February 3, 10, 17, and 24.

POSITIVES.—Will you please tell me the best way to make a good positive, whole-plate size? Can I obtain lantern plates of that size and print by gaslight?—A. G. NEWARK.

Your question is not quite clear. You can easily make a whole-plate positive by contact by gaslight if your original negative is that size, or by enlargement if it is smaller. An ordinary slow dry plate answers for the purpose, or you can obtain transparency plates coated with the same emulsion as lantern plates. The positive should not be too hard in contrast unless it is intended for decorative purposes.

COPYRIGHT.—Will you kindly inform me if I can legally copy a photograph of a group, taken in South Africa, and stamped "Copyright"?—COPYRIGHT.

No, certainly not. Although the administration of copyright law in South Africa is very lax, copyright in British colonies extends to this country under the terms of the Berne Convention.

MAKING CAMERA.—I propose making a half-plate camera for general use. Please advise which is the better method, front or back extension, also what length should it be capable of extending. Which bellows would you suggest, square or taper?—E. W. HENLEY.

You will find that a rigid-back camera, with front extension and good rising and swing front, will be most generally useful, unless you intend using lenses of very short focus, in which case the back should be made to move up to the front, or the baseboard will cut off some of the picture. The camera extension depends to a great extent on the class of work you intend doing. In any case it should be at least double the focal length of the lens you intend using, as this will permit you to copy same size. Bellows with a very slight taper will be found best for most purposes.

"CONSTANT READER."—You must give your name and address; also the prints for criticism as to retouching must be toned and finished.

REGISTERED NAME FOR POSTCARDS.—I am about to publish some postcards, and, wishing to give a name to the series, I shall be glad if you can inform me: 1. Where I could see a list of names already used by publishers of postcards? 2. What is the procedure and the cost of registering a name for this purpose?—S. C.

1. There is none that we know of, except in the catalogues of the leading postcard publishers, and the columns of a paper

such as the "Picture Postcard" (monthly). 2. You can obtain the regulations as to registering trade names from the Comptroller of Trade Marks, Southampton Buildings, Chancery Lane, London, E.C. The fees are 5s. on application and £1 on registration.

SOLAR ENLARGEMENT.—Can you inform me of the best method of making plain silver enlargements on paper and canvas by development; also how to obtain a sepia tone on some, either by development or after treatment?—**ENLARGER.**

In all probability the process required is the old calotype process, in which the paper is floated on potassium bromide 60 grains, water 8 oz., and then dried and sensitised on silver nitrate 110 grains, citric acid 15 grains, water 8 oz., and dried; after exposure it may be floated on a weak solution of silver nitrate 1:20, and then developed with a saturated solution of gallic acid at about 80 deg. F. This gives warm blacks, but is very slow. A more satisfactory formula is:—

Potassium iodide	80 grains
Ammonium bromide	35 grains
Ammonium chloride	10 grains
Gelatine	60 grains
Albumen	1 ounce
Distilled water	10 ounces

Soak the gelatine in the water and dissolve by the aid of heat; add the salts and allow to cool, and then add the albumen. Spread this solution over the paper or canvas with a soft sponge, and when dry sensitise with:—

Silver nitrate	1 ounce
Glacial acetic acid	$\frac{1}{2}$ ounce
Distilled water	10 ounces

A small pool of this should be poured on to the canvas or paper and distributed with a clean sponge or cotton wool, and the paper should be exposed wet; the exposure for an enlargement about six times with a good light is about one minute. The developer is:—

Gallic acid	60 grains
Acetate of lead	10 grains
Distilled water	10 ounces

and should be applied with the same sponge as the sensitiser is distributed, or a little silver solution should be added to above. For sepia tones it would be advisable to bleach with ferricyanide, and then apply sodium sulphide solution, about 1 per cent.

T. W. BARBER.—The transparencies have not been properly washed and are now showing the effects in the shape of probably sulphur deposit of some kind in the gelatine; we hardly think it likely that you can clear them now.

FLASHLIGHT GROUP.—The lighting of the group is very harsh. A better result would have been achieved if another flashlight had been used to lighten the shadow side. The photograph is not likely to have much more than a local sale, or be very interesting to many beyond those concerned in the group. Kindly supply your name, not necessarily for publication, when sending queries in future.

COPYRIGHT.—(1) What is the penalty for marking a photograph "copyright" if it has not been registered? (2) What would be the sharpest way to get them registered and to know they were registered before disposing of them? (3) Is it possible for a photographer to take a photo here and sell them three hours afterwards and have them registered?—**W. H. J. E.**

(1) The act is illegal, but we do not know of a case

of proceedings having been taken for the illegality. (2) and (3) All photographs must be sent to Stationers' Hall, Ludgate Hill, London, E.C., to be registered, hence the rapidity with which they can be registered depends on the facilities of transit. A receipt bearing the registered number of the picture is sent from Stationers' Hall if a stamp be enclosed for that purpose, and a certified copy of the entry of registration is obtainable for 5s., and is legal evidence of the claim to ownership of the copyright.

ARTIFICIAL LIGHT.—I have two arc lights, 5,000 c.p. together, a room 25 by 14, with high side window. Shall be glad to know best way to illuminate the sitter. Should the light shine direct, or be reflected by some means? Any help will be greatly appreciated, as I have never used electric light.—**J. D.**

We should say that the best way would be, as the lights are so small, to have them enclosed in ground glass globes or cylinders, and to place one at side, and a little in front of the sitter, to serve as a dominant light, and the other more forward, and more in front of the sitter, so as to soften the shadows. You do not say the size and position of the window, or whether you wish to supplement the electric light by that, or we might help you further.

STUDION.—1. The position for the sitter, as shown on the sketch, will be as good as any, and the light will serve fairly well for small pictures such as you propose to take. Of course, it would not do for full length pictures of a large size. 2. The sulphocyanide bath is what is generally used by professional photographers for P.O.P. With it you should not get double tones if you properly wash the prints before toning them.

"EN AVANT," G. Z., and others.—In our next.

THE Kodak Photographic Exhibition was opened last week in the Ulster Hall, Belfast, by Sir James Henderson. Mr. H. C. Shelley is lecturing and demonstrating, and the show is meeting with great success.

COLOUR PHOTOGRAPHY.—"Mr. F. Styant-Browne (President of the Pharmaceutical Society of Tasmania), who has for some time been experimenting with a view of producing colour-photographs, has succeeded in producing a photograph of a group of fruit, the colours of which are distinct and true to nature. The print is untouched in any way, and is stated to have been produced entirely by photography." So reports the "Chemist and Druggist," with unnecessary insistence on the photographic character of the process.

THE address of F. G. Willatt, High Wycombe, should be 157, Gordon Road, not 15½ as stated recently in another column.

**** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

The British Journal of Photography.

EX CATHEDRA.

The Free Enlargement in Ceylon.

Several copies of the "Ceylon Independent," which a correspondent is good enough to send us, we see that the old offer of an enlargement free is not varied when the scene of action is shifted to the East. There as here, M. Tanqueray occasionally makes a friend at court by actually fulfilling the strict letter of his offer, and thus obtains defence against those of his victims who naturally enough are not averse to exposing his methods of business. Ceylon has recently been deluged with the Tanqueray circulars, but we are glad to find the "Independent" cautioning its readers against the swindle.

Local Customs and Photography.

The inspection of some interesting photographs sent us by a correspondent in Cornwall has aroused our wonder as to the vogue of quaint local customs that exist to-day in various remote corners of the kingdom, and whether they are being recorded by the camera for the delectation of future generations. We have already referred to the praiseworthy labours of the National Photographic Record Association, and are well aware of the extent of Sir Benjamin Stone's collection of record photographs, but so far, we are unaware of any organised attempt being made to get together representations of local customs in addition to photographs of archaeological interest. The photographs sent us depict the crowning of the May Queen and plaiting the May Pole, in a remote Cornish village. The glories of Jack-in-the-Green and his compeers have, alas, departed, or have been driven into the quiet backwaters of country districts by the exigencies of modern rush and bustle, that have no time or place for these picturesque junketings, but it is surely a matter for regret that these customs, and others such as rush-bearings,

beating the bounds, fairs and feasts, etc., that have found universal acceptance at the hands of the people at one time, should pass away unrecorded by that most conscientious servant of the graphic arts: photography.

The Non-Return of Specimens.

Complaints of the retention of photographs—specimens of operating or retouching—by those advertising in our columns are greatly diminished in number of late, and we are glad to find that few employers are so destitute of the ordinary instincts of a gentleman as to retain specimen prints when their return is expressly prepaid. On the other hand, it is satisfactory to note that assistants are now more specific in their requests, and punctilious in enclosing the necessary postage and addressed envelope, for the return of the prints. Some persons, nevertheless, still appear to think that an advertiser's duty is to return at his own expense the forty or fifty specimen prints which may reach him, and whilst complaints that come to us because he does not do so have not the faintest justification, the breed of unscrupulous creature who will not take the trouble to return prepaid photographs to their owners is not quite extinct. However, there is consolation in the fact that photography is not the only profession in which these reprehensible practices still linger. Theatrical advertisers, we are told, are worse sinners, and even the "Lancet" thinks it necessary to caution certain of its advertisers engaging assistants and locum tenens. Its sharp note is one which we hope will duly deter those in the wrong:—"Photographs are the property of the gentlemen whom they represent and who pay for them; they are lent to advertisers for mutual convenience and when their purpose has been served they should be returned. As no one can want to make a collection of the photographs of perfectly strange gentlemen it is clear that the retention (of which serious complaint is occasionally made to us) is due only to carelessness, but people have no right to keep the property of other people whether the act results from carelessness or otherwise. In the case of a frequent offender we should like to hear what argument he is prepared with that should prevent us from violating the ordinary rule of editorial discretion and giving his name to his outraged victims."

A Rival of Persulphate.

A new reducer of the silver image which is stated to resemble ammonium persulphate in its effects, but to be slower and more manageable in its action, forms the subject of a communication by Mr. Harry E. Smith to the "Photographic Journal." The substance used by Mr. Smith is one or other of the numerous complex cobaltamine salts in acid solution. Erdman's salt, $\text{Co}_2(\text{NH}_3)_4(\text{NO}_2)_2\text{K}_2$, is named as one of the best for the purpose, and the reducer is prepared by dissolving .25 gramme of it in 50 ccs. of hot water,

and when cool, adding 50 ccs. of 15 per cent. sulphuric acid. The reduction takes place slowly, and on the highlights of the negative in preference to the shadows. It is recommended for bromide prints. After a brief wash, following reduction, the negative or print is immersed in 10 per cent. ammonia for about three minutes, and finally washed. We shall be glad to hear that the new agent is equal to persulphate in its "softening" action on a hard negative, but it is a pity that so acid a solution is necessary to give it activity. We demur to putting negatives into $7\frac{1}{2}$ per cent. solution of sulphuric acid, and to subject them afterwards to 10 per cent. ammonia. Such a course of treatment is likely to injure the substance of the gelatine, and to favour the separation of the film from the glass.

Photographing Further information is now to hand as the Corona.

to M. Hausky's method of photographing the solar corona in daylight, to which we referred last month. He uses celluloid films from which the silver salts have been dissolved, stains them in solutions of aniline dyes, red, orange, malachite green, and gentian violet, and then superimposes them on a red-sensitive plate; the light absorbed by this combination of screens reaching from wave length 660 to the ultra-violet. In contact with the front of the screens he places an opaque disc which cuts out the image of the photosphere itself. So far some twelve successful results have been obtained with exposures from thirty seconds to two minutes. Further trials are to be made with screens limiting the light as far as possible to the red C. line, and adopting the plan of placing the occulting disc at some distance in front of the lens so as to avoid reflections in the interior of the camera.

Photographs of the Solar Corona.

Reference was made last month to the attempts by Dr. Hausky to photograph the solar corona by the use of screens, and in connection therewith mention was made of Professor Hale's work. We have now received from Dr. Wm. J. S. Lockyer, of the Solar Physics Observatory, South Kensington, a reprint of a paper by him in the monthly notices of the R.A.S., in which he describes the spectro-heliograph used at the aforesaid observatory, which may be said to be an improvement on the Hales-Deslandres instrument. In this the sun's image is thrown on a slit by a siderostat, and is then dispersed by a prism. The image of the spectrum is formed at the plane of a secondary slit, which is curved to the exact radius of the curvature of the K line of calcium. Close behind this slit is placed the plate, and the primary slit is moved across the image of the solar disc, and a complete image is formed of the solar surface, on the stationary plate. When pictures of the corona are required the actual image of the sun is, as it were, eclipsed at the primary slit by a circular plate of metal. Otherwise the disc would be considerably over-exposed, as it requires but one-sixtieth of that for the corona. Some interesting results are illustrated, and doubtless many of our readers will remember that some have been exhibited in the technical section of the R.P.S. Exhibition during the last few years.

Honorary Fellows of the R.P.S.

The brief intimation in our last issue that four new honorary fellows had been elected by the Council of the Royal Photographic Society might be received with little comment beyond an appreciation of the new resolution that "it is desirable that the award of the Progress Medal should be accompanied by the Honorary Fellowship."

But when it is seen that the names of Robert Demachy and Alfred Stieglitz are included in the quartette, the announcement takes on a more portentous aspect. That Robert Demachy can be regarded as the representative of pictorial photography in France, and that Alfred Stieglitz occupies a similar position among the American photographic pictorialists, are undeniable facts. Hence the special singling out of these two personages can only be regarded as a premonitory step in the direction foreshadowed by the R.P.S. in their last exhibition at the New Gallery. The foreign and American invitation section on that occasion left no doubt as to the trend of the society towards an acknowledgment of the modern pictorialism as demonstrated in this country by the "Linked Ring." Is the present step intended to lead towards a possible conciliation and amalgamation between the two annual picture shows? Such an idea has been put forward, but we cannot seriously expect anything to come of it, and we certainly fail to see that pictorial photography would stand to gain by the removal of healthy rivalry.

Weather Prog- The proverbial vacillations of English nomenclatures.

weather have often proved a stumbling-block to the enterprise of both professional and amateur photographers. Fine bright days are, at this time of the year, expected; but how often it is the unexpected that happens. Not only is the ardour of the photographic society excursion summarily damped, but the individual members thereof are frequently deprived by sudden spells of gloom and storm from perpetrating further incursions into the realms of practical photography. For this we might at times be thankful were it not for the fact that the photographer, whose bread and butter depends to a great extent upon the vagaries of the light, is also concerned. A definite knowledge of what the day after to-morrow is likely to give in the way of weather is, therefore, likely to prove of value to every user of the camera. Steps towards the consummation of this ideal state of things were successfully taken by the "Daily Telegraph" last year, with a series of weather forecasts sent per Marconigram by Atlantic liners when 1,000 miles or more west of the Lizard. The system has again been started by that paper, and if the predictions given are used in conjunction with local indications, they should prove of great usefulness to photographers throughout the country. In addition to this the Meteorological Council announce that, as in previous years, they will send out during the summer months a special service of forecasts for the benefit of agriculturists and others. These forecasts cover the period of the hay and corn harvests, from June 1 to September 30, inclusive. For this service special telegraphic reports are obtained up to 2 p.m., and the anticipations are sent out daily at 3.30 to those "who desire to receive them and who defray the cost of the telegrams." This outlay is practically 6d. a day, for the message contains only nine words, plus the address. Up to the present time the Midland Counties and the South of England have shown the greatest appreciation of this service, and last year over 80 per cent. of the prognostications were successful.

The Dublin Convention.

An advance copy of the official handbook of the forthcoming twentieth Annual Convention of the United Kingdom has been sent us. The little booklet—in an appropriate green cover this year—again bears witness to the energies of Mr. F. A. Bridge, the hon. general secretary and treasurer, and his local collaborators. The book is similar in form to that adopted in previous years, and much useful information is contained therein, albeit the bulk of the matter is

uide book." Dublin itself is dealt with in a general view, historical and otherwise, and Glendalough, Bray, the Dargle, and Drogheda and Monasterboice also in for a full share of graphic description which could prove of undoubted service to conventioners intending to take advantage of the special excursions to these parts of Erin's Isle in July next. The frontispiece is a portrait of the president elect, Professor John Joly, R.S., D.Sc., etc., from a negative by Alfred Werner, many admirable illustrations of places of interest in and around Dublin are included. Old conventioners who visited the city in 1894 will look forward to renew their acquaintance with the places depicted. We have already published the programme of arrangements for the week, commencing July 10, and in our next issue will, for the benefit of our readers, reprint the entire programme as set forth in the handbook, and in particular will draw attention to the announcement that the hon. general secretary has arranged with the London and North Western Railway Company to reserve special accommodation for members of Convention, by the excursion leaving London (Euston) on Thursday evening, July 6. Several conventioners have already signified their intention to travel by this train, and Mr. Bridge is pleased to welcome any others desirous of joining the party. Applications should be addressed, Mr. F. A. Edge, East Lodge, Dalston Lane, London, N.E., and must be received not later than Saturday, July 1, and must be accompanied by a remittance for the return fare Dublin (26s.).

WEIGHTS AND MEASURES.

"Bothers of our weights and measures are like weekly —with us always," was one of the happy phrases used by Lord Crawford in his presidential address to the Royal Photographic Society in 1897, and it is one which comes to mind on looking over the correspondence which has lately appeared in our pages. One has only to turn back past volumes to see that this subject is a sturdy perennial.

The whole question would be at once simplified were the metric system adopted, or if the suggestion of some uniform form of expression were adopted by manufacturers and photographic writers generally. For were all units expressed in grains per ounce, or the total bulk of solutions made up to one common measure, such as 100 ounces, it would be extremely easy, on the adoption of a new formula, to see in what and by how much it differed from existing ones.

It would, of course, be absurd to adopt the suggestion of making the total bulk of all solutions up to the pint, as, for instance, in the case of gold and platinum solutions, it would also be ludicrous to give a fixing bath in 100 grains per ounce. We have taken these two examples as practically typical of our working solutions, and the natural corollary is that absolute accuracy is in many cases only unnecessary, but practically impossible. If we were to strive for this, we must necessarily take into consideration barometric and thermometric conditions; and, moreover, in many cases — in fact, it may be said practically all cases — scientific accuracy is impracticable and unnecessary. The difference in result by the addition of a grain of pyro per ounce, or a slight excess or deficiency of hypo, cannot be appreciated in practice.

It is, however, to the specific points raised in the last discussion. With regard to the dubious point of the total bulk of solution, mentioned in the original letter in our issue for April 21, it seems only reasonable to suppose that in all cases the total bulk of the solution should

measure that given, and that "water x ounces" should be inferred to mean "water to x ounces." If the reverse is accepted, then it would mean that (in many cases) for the making up of a formula in which "water 20 ounces" was given we should have to use a bottle of a slightly greater capacity than one pint.

The question of the 10 per cent. solution should not present any trouble, if it is remembered that all chemicals are sold by the avoirdupois ounce of 437.5 grains, and not by the old apothecaries weight of 480 grains. In our judgment, photographers mean by a 10 per cent. solution one which contains 1 grain by weight of the solid in 10 fluid minims of the solution, and, therefore, such a solution is made by dissolving the avoirdupois ounce in sufficient water or solvent to make the total bulk measure 4,375 minims, equal to 9 oz. 55 minims fluid. In precisely the same way, any other strength solution may be made, by multiplying the solid in grains by the necessary factor and making the total bulk of solution measure this volume.

The next point we have to consider is that of the conversion of metric formulæ into English; the reverse is rarely required. We may at once state that the use of the cubic centimetre, whilst academically incorrect, should be adopted by those who wish to write in metric measures, as this brings the formulæ into line with those used on the Continent. Taking the specific instance given in the original letter:—

	A.	B.
Hypo	400 grammes.	8 oz. 3840 gr.
Sodium chloride	20 grammes.	175 gr. 192 gr.
Lead acetate	10 grammes.	87.5 gr. 96 gr.
Gold chloride (1 p.c. sol.)	100 c.c.	2 oz. 2 oz.
Water to	1000 c.c.	20 oz. 20 oz.

It is obvious that it is perfectly immaterial whether we adopt the A. or B. reading, in regard to the first three ingredients, so long as we keep to the correct quantity of gold, which is the important constituent, and this we shall do if we make up our 1 per cent. solution as advised above.

Incidentally we may remark that in the metric formula the first three ingredients form a 40 per cent., a 2 per cent., and a 1 per cent. solution, and, therefore, to obtain these, the quantities must be as in B. formula. But few of us would think of weighing out 3,840 grains of hypo. We should at once take the familiar half-pound avoirdupois, though by doing this the actual error would be over three-quarters of an ounce in the amount of the hypo.

As regards the formulæ in the next issue of our ALMANAC, we may state that the above considerations will guide us in conversion of the metric into English formulæ, and as regards the reverse, we shall adhere to Lord Crawford's suggestion of dividing the grains per ounce by half the number of ounces in the total bulk of solution. This is a practical method, if not theoretically correct. To use the exact factor would give, in the majority of cases, two or three places of decimals, and to find fault with this system when dealing with such quantities as a total bulk of 1,000 c.c., because of this slight discrepancy of a few milligrammes would be nothing more than academic hair-splitting.

With regard to the queries in the letter in our last issue, these must be answered with reference to each particular case, and it will not be difficult to decide this if the quantity of the developing or other agent be calculated when A. and B. are mixed together, and also if an equal volume of water be added, or only half. The word "part" should present no difficulty, as long as this is read as meaning one particular unit, such as "ounce," "pint," "grain," or "gallon."

INTERNATIONAL AND FOREIGN COPYRIGHT.

WITH the growth of illustrated journalism, the photographic record of the doings of the world becomes more and more important. The outlook upon the affairs of the civilised globe now accorded to the reader of a daily or weekly newspaper is wider than ever it was, and many subjects, which a few years ago would be deemed of national interest only, are given a place in the illustrated periodicals of different countries. Photographers, as the chief creators and purveyors of this illustration, have reason to keep a keen eye on this tendency, inasmuch as it opens markets to them in foreign countries. While the British illustrated press accepts, and even seeks, work from abroad, the foreign press of the same character does not ignore the doings of the week in the dominions of His Majesty, King Edward VII. Take up a good illustrated paper in Berlin, such as "Die Woche," and you will find depicted therein Mr. Balfour at golf, or a typical picnic scene on the upper Thames. Such uses of foreign illustration are indications of the growing international character of picture journalism. As means of transit become more rapid, and reproduction methods are improved, the growth will be propor-

tionately more vigorous. At any moment the tendency to receive a sudden impetus by some new process of reproduction which may revolutionise current methods. Telegraphic transmission of pictures, for example, is a process at present in an embryonic condition, which may reach the practicable stage. The lesson of the past twenty years teaches us that the illustrated press of the future will bring to an even sharper focus the doings of the inhabited globe. Political economists may see in this prediction of the closer union of the nations and a more pacific state of international politics from the better acquaintance of the various peoples. With that aspiration we have nothing to do. We would come to a more sordid aspect of the question—one affecting photographers—that is, the protection which is granted to photographers in foreign countries. It is conceivable that foreign copyrights may become of much greater monetary importance than they are at present, and, for that reason, it may not be out of place to draw attention to the legislation under which works of art, including photographs, are granted protection. The present law came into operation in 1886, and is known as "The International Copyright Act."

THE INTERNATIONAL COPYRIGHT ACT.

This Act was passed in 1886. In 1887, the Berne Convention was signed by Great Britain. Under this Convention, the subscribing countries (forming the "Copyright Union") agree to certain mutual protection of literary and artistic works. The essence of the Convention is found in Article II., wherein it is provided that authors of any country of the Union shall enjoy in all the other countries for their works, either published or not published for the first time in one of those countries, the rights which the respective laws grant to natives, except that the term of protection is not to exceed that in the country of origin. In other words, a foreigner gets the same privileges as a native, except as regards duration of copyright.

An essential condition of the acquirement of protection in the foreign countries is that the author's procedure must be such as entitles him to protection at home. He has not to trouble himself about the formalities in other countries, but he must observe those of his own, or the "country of origin," as it is better to term it. The Act defines the "country of origin" as that in which the work is first published.

Registration of a photograph is not necessary to ensure its protection in the countries subscribing to the Convention. Though this point has been in dispute, the above seems to be the inference from the case of *Hanfstaengl v. Holloway*, some ten or more years ago. Coppinger, writing on the subject in his "Law of Copyright," concludes that "the Englishman who complied with the requirements of English law was to be protected in the foreign countries of the Copyright Union."

Another point which may be extricated from the intricacies of international copyright law is that an author cannot claim the benefit of a greater length of protection, if it exceed that conferred by the legislature in the country where he publishes.

These few extracts from the law on the subject will serve as a guide to the photographer having relations with publishers abroad in the matter of complete or partial assignment of copyright. To make them complete, we give a brief summary of the copyright laws of the countries of the Union, especially in relation to photographers.

COPYRIGHT LAW OF FOREIGN COUNTRIES.

The following is a condensed account of the regulations as to photographic copyright in the foreign countries of the Copyright Union, i.e., Belgium, Denmark, France, Germany, Hayti, Italy,

Japan, Liberia, Luxembourg, Moravia, Norway, Spain, Sweden, Switzerland, and Tunis.

COUNTRY.	DURATION OF COPYRIGHT.	CONDITIONS.	FORMALITIES TO BE OBSERVED.	NOTES.
Belgium ..	Fifty years after the death of the author	None	None
Denmark ...	Five years after the death of the author	All copies must bear the author's name and the words "Exclusive property"	Declaration must be made at the Department of the Interior and one copy deposited. The declaration must state the full name of the photographer, a description of the photograph, and, if the photograph is reproduced from a work of art, the name of the artist	Actions for infringements can only be brought by an injured party and within a year and a day. Persons infringing or selling or importing pirated copies are liable to fine and to indemnify the injured person.

COUNTRY.	DURATION OF COPYRIGHT.	CONDITIONS.	FORMALITIES TO BE OBSERVED.	NOTES.
France*
German Empire	For five years from the end of the year in which the first copies appeared, or from the making of the negative	Every photographic or photo mechanical copy must bear, either on the picture or the mounting, the name or firm of the photographer or publisher, his address, and the year in which the reproductions first appeared	None	Photographs are granted protection in Germany only when made by Germans. (This applies to photographers resident in Germany, so that an Englishman can obtain protection by registering in England which would not be granted to him were he resident in Germany.)
Italy	For life of the author and life of his widow. If he leaves no widow, the copyright passes to his children for twenty years, or to other heirs for ten years	...	Five copies to be deposited at the Department of the Interior	...
Italy	In artistic works, first for the life of the author or forty years, whichever is the longer, then for another forty years, during which time reproduction can be made on payment to the author of 5 per cent. of the published price of each copy	...	Three copies must be deposited, with description of same stating year of publication and desire to reserve rights as author or publisher. The declaration must be made within three months of first publication, but it can be made at any later time within ten years, unless the work is reproduced in the meantime or copies imported from a foreign country	...
Japan	For ten years from publication: or taking of negative, if not published	...	Registration is made in the Department of the Interior. In default of registration a civil action for infringement cannot be brought, nor can the copyright be mortgaged or transferred	Lawful reproductions of a work of art enjoy copyright as long as the copyright lasts in the original. The right to reproduce photographic portraits belongs to the person who has ordered them.
Luxembourg	Fifty years after the death of the author
Monaco	For the life of the author
Norway	For five years from the expiration of the year in which the first copy was made, but terminating in any case at the death of the photographer	The word "Einbertigt" (protected) must appear on each copy, also the date of production, the name of the photographer, and the name of the artist if the photograph is a copy of a work of art	Norwegian authorities have notified the Berne International Bureau that no formalities need be observed for the creation or maintenance of copyright or as a preliminary to taking action for infringement, but a law of 1882 demanding registration appears to be still in existence	...
Spain	For the life of the author and eighty years after his death	...	No registration or deposit is necessary in general for works of art	...
Sweden	For five years after publication	Each copy must bear the name and address of the photographer and the year of first publication
Switzerland	Five years after registration	...	Registration must be made at the Federal Department within three months	...
Tunis	For the life of the author and fifty years after his death

* According to Coppinger ("The Law of Copyright," 1904 edition, page 554), copyright in photographs in France has been greatly a matter of controversy, photographs not being expressly dealt with under any legislation. It has been held (1) that all photographs are protected under the law of July 19, 1793, by which the copyright in works of art endures for fifty years after the death of the artist; (2) that no photographs are protected; (3) that only photographs of artistic merit are entitled to protection. The general decisions of the courts seem based on the third alternative. The judges decide whether a photograph is a work of art or not, and their decision can be taken to the highest court of appeal. The French law of 1902 grants copyright to designs of buildings, and an architect can prevent a photograph of a private building being taken for purposes of profit.

MODERN CHEMISTRY FOR PHOTOGRAPHIC WORKERS.

IV.—EQUILIBRIUM, AND THE FINAL RESULTS OF REACTIONS.

In the earlier papers of this series we have discussed the behaviour of solutions, the splitting up of compounds into ions, and the functions of those ions in determining the nature of reactions. It will next be desirable for us to investigate the progress of these reactions both as regards the end to be attained by any given reaction, which we may call the statics of reaction, and as regards the rate of reaction itself, which we may call the dynamics of reaction.

Reversible Reactions.

In the second paper of this series* we saw that while ammonium chloride will on heating split into ammonia and hydrochloric acid, so also on cooling will ammonia and hydrochloric acid form ammonium chloride. If we place either ammonium chloride, or an equivalent quantity of ammonia and hydrochloric acid in a bulb, we shall find that under fixed conditions of temperature and pressure we have always the same final products in the bulb—that is to say, we shall have ammonium chloride, ammonia, and hydrochloric acid in some proportions.

If we start with ammonium chloride, some of this will dissociate into ammonia and hydrochloric acid; if we start with ammonia and hydrochloric acid, some will combine to form ammonium chloride.

So that we have here a reversible reaction which we can write

The Law of Mass.

If we look at this a little more closely, we shall be able to understand the mechanism of the reaction. If we start with a definite amount of ammonium chloride, then a certain number of molecules every second will split up into ammonia and hydrochloric acid; if we start with ammonia and hydrochloric acid, a certain probably different number of molecules will unite to form ammonium chloride. To get the matter quite clear, let us look at an analogy. Suppose the Bath express leaves London at the same time as the London express leaves Bath, which is 106 miles from London, and suppose the Bath express travels at fifty miles an hour, while the London express travels at forty miles an hour, where will they meet?

The answer can easily be worked out. In the same way the ammonium chloride is turning into ammonia and hydrochloric acid with a certain velocity K , and the ammonia and hydrochloric acid are turning back into ammonium chloride with a certain velocity K^1 , so that presently we get to a point, for any temperature and pressure, where the number of molecules of ammonium chloride dissociating is equal to the number re-combining, and we have reached an equilibrium. This equilibrium is fixed by the mass law, which states that *The velocity of any reaction depends on the concentration of the substances taking part in that reaction.*

This is so obvious as to be almost axiomatic, and yet it remained almost unused until quite recent times.

Suppose, for instance, 2 grams per second of ammonium chloride are formed from 10 grams of ammonia and hydrochloric acid, the mass law states that 4 grams will be formed from 20 grams, and so on.

From this it will follow that all reactions are reversible provided that the products of reaction are not removed.

For instance, the splitting up of potassium chloride into ions will be reversible, but the action of sulphuric acid on zinc

will not, because the hydrogen which is formed is removed as gas.

Similarly, if we add silver nitrate to potassium bromide solution a reaction occurs which we can represent by the ionic equation

but this reaction is not reversible, because the AgBr is removed from solution by being precipitated.

To return to ammonium chloride. Suppose that the reaction

goes with a velocity K , and that under the same conditions of temperature and pressure the reaction

goes with a velocity K^1 . Then the number of molecules converted per second in equation (1) will depend on K , and on the concentration of the NH_4Cl , or

$$\text{Number converted per sec.} = K C_{\text{NH}_4\text{Cl}}$$

where $C_{\text{NH}_4\text{Cl}}$ = Concentration of ammonium chloride in gram-molecules per litre.

In the same way, the number of molecules converted per second in equation (2) will depend on K^1 , and on the concentration of the ammonia and the hydrochloric acid, or

$$\text{Number converted per sec.} = K^1 C_{\text{NH}_3} C_{\text{HCl}},$$

where C_{NH_3} and C_{HCl} = concentrations of these substances in gram-molecules per litre.

(A gram-molecule per litre is the molecular weight in grammes dissolved in a litre of solution, and is the unit of concentration. It is usually called a mol in physico-chemical text-books.)

At the equilibrium point these two numbers converted per second must be equal, so that

$$K C_{\text{NH}_4\text{Cl}} = K^1 C_{\text{NH}_3} C_{\text{HCl}}.$$

which is the equilibrium equation.

If we consider this equilibrium equation, it is clear that if we add excess, say, of ammonia to the bulb, and so increase C_{NH_3} , we must correspondingly increase $C_{\text{NH}_4\text{Cl}}$, that is to say, less ammonium chloride will be split up. In other words, adding the product of a reaction decreases the amount of the reactive substance decomposed. Of course, the equilibrium equation applies to all possible reactions; it applies, for instance, to ionic dissociation. We saw that on solution potassium chloride dissociated into ions according to the equation

but this is reversible, and we can write for the equilibrium

$$K C_{\text{KCl}} = K^+ C_{\text{K}^+} C_{\text{Cl}^-}$$

and we see from this that the addition of other potassium ions—potassium nitrate, for instance—will lessen the dissociation of potassium chloride by increasing the value of C_{K^+} .

It has already been stated that development proceeds between developing ions and dissolved and ionised silver bromide. Silver bromide in the very dilute state in which it could occur in a plate is very highly dissociated, but if potassium bromide be added to the developer the concentration of the bromions is greatly increased, and consequently the dissociation of the silver bromide is diminished and there are many less silver ions present for reaction.

A most important example of equilibrium occurs in the case of complex ions. It frequently occurs that some body not itself soluble combines with some other substance to form

* THE BRITISH JOURNAL OF PHOTOGRAPHY, May 12, 1905.

soluble ions. For instance, ferrous oxalate, which is an insoluble yellow powder, combines with the oxalic ion to form complex ferro-oxalic ions, which are soluble in water, thus:—

The equilibrium equation for this reaction will be

the value of $\frac{\text{K}}{\text{K}_1}$ has been found to be .8 by actual measurement. Another dissociation might take place in this case, namely, the ferro-oxalic ion might re-dissociate into ferrous and oxalic ions:—

but at moderate dilutions this only occurs to a very small extent.

Another interesting example of a complex ion is to be found in the case of silver thiosulphate, which appears to form with sodium thiosulphate a soluble complex ion. Probably also the metallic ferrocyanides form complex ions with citrates, since they are soluble in them, but all these cases need investigation. In the case of all equilibria, it has been pointed out that the equilibrium only persists at one definite pressure and temperature; that is to say, alteration of these conditions will disturb the equilibrium.

If, for instance, ammonium chloride has reached the equilibrium indicated by the equation

and we heat the bulb, we very greatly increase the velocity of

dissociation of the ammonium chloride, or K_1 and consequently get CNH_4Cl diminished, and CNH_4CHCl increased; that is to say, very much more ammonium chloride dissociates.

Hence we see that any alteration in conditions which will affect the velocity of a reaction without also affecting the velocity of the reverse reaction, will affect the equilibrium. Certain reactions appear to be greatly accelerated by small quantities of substances, and these bodies are termed catalysers. In some cases we understand the action of the catalyser; in many others we do not.

For instance, ethyl acetate in the presence of water very slowly dissociates into alcohol and acetic acid, according to the equation

This reaction proceeds at a very much greater rate in the presence of hydrogen ions—that is, upon the addition of an acid. In fact, the alteration of velocity of this reaction is the usual way of measuring the number of hydrogen ions in an acid solution.

This reaction, however, is catalysed to an equal extent in both directions, and so are all other catalytic reactions; that is to say, catalysers do not affect the final equilibrium. Both the velocity and the equilibrium of reactions may be very greatly affected, however, by alterations of temperature, concentration, etc.

To sum up, reactions are shown to proceed to an extent both forwards and in the reverse direction, which is determined by the velocities of the two opposing reactions and by the concentration of the reacting bodies. In the next, and concluding, paper we shall enter upon the dynamical aspect of reaction, that is, the rate of progress of a single reaction before the equilibrium position is reached.

C. E. KENNETH MEES, B.Sc., F.C.S.

THE WEEK IN HISTORY.

Poitevin's Gelatine Dry Plates, 1850.

MAY 27, 1850—fifty-five years ago to-morrow—is the day on which Poitevin communicated to the French Academy of Sciences a description of a gelatine dry plate. Not an emulsion, of course, but none the less a silver iodide gelatine plate prepared somewhat after the Daguerreotype by exposure of a gelatine film containing silver acetate to the vapour of iodine. Poitevin coated glass plates with gelatine and soaked them in solution of silver acetate. Saturation of the gelatine film with silver in this way was done the evening before the plates were to be used. The next morning they were exposed to the iodine vapour, as were the silvered plates of the Daguerreotypist, and placed forthwith in the camera. Yet Poitevin mentions the increase in sensitiveness which is obtained if the plates were left for some time between iodising and exposure. Some idea may be gained of the feeble sensitiveness of these plates by the exposures of two minutes necessary when working with portrait lenses, and of eighty to one hundred seconds for landscapes in a good light. The developer was a one-tenth per cent. solution of gallic acid, which was employed for an hour or an hour and a half. After fixing in one per cent. hypo, the plate was washed and transferred to a solution of potassium bromide, again washed, and dried. The object of the bromide bath is not clear, and in a subsequent paper on the process Poitevin omits it.

Moist Collodion Plates.

The search for a dry-plate process is an overpowering element in the records of the experimental work of about fifty years ago. I have referred before to the labours of Gaudin, most of whose papers appeared in "La Lumière." In 1854—on May 27—Gaudin continues to discourse on his efforts to work the collodion as a dry, not a wet, process. A film with silver nitrate in it,

he reasons, cannot be kept, for the silver iodide is dissolved from it as the silver solution becomes stronger by evaporation. Form your silver iodide, he concludes, and remove the excess of silver before exposure, afterwards replacing it before development; or adopt the method of Crookes and Spiller of keeping the film moist with a deliquescent salt ("The Week in History," April 28). He finally recommends, as a process suitable for occasions when the plate has not to be kept for a very long time, the use of a 5 per cent. sensitising bath containing nitrate of zinc and white sugar, the plate before development being given an immersion in a full-strength silver bath.

R. F. Barnes worked a *dry*-plate process, and published a pamphlet upon it in the middle fifties. I recollect his working it in 1856, and he published 12 by 10 views of London about that time.

Fox Talbot's Plates.

The calotype process, as I have already mentioned, was patented by Talbot in February, 1841 ("The Week in History," February 3). It is not to be supposed that Talbot rested satisfied with it in its original shape, although he spent four years in bringing it to its state of perfection at that time. Two years later, on June 1, 1843, he took out a patent which claimed protection for a number of little odds and ends, such as would occur, one might expect, to any one working the process. For he patented:—

A hot solution of hypo to improve the whites of the picture and give permanence;

Increasing the rapidity of the paper by placing a warm iron plate behind it during exposure;

"Io-gallic paper"—i.e., iodised paper treated with gallic acid and requiring only silver nitrate to render it sensitive;

Waxing paper prints to render them transparent, and

backing with white or coloured papers to obtain "various beautiful tones of colour";

Making enlarged paper negatives and printing therefrom on calotype paper;

And, the publication of photographic prints.

The last item is probably the most extraordinary of Talbot's

patent claims, for he does not put forward as novel any process or apparatus, but claims as new the system or combination of these several processes into one, whereby a new and useful result is produced, viz., "The multiplication of very permanent and perfect photographic copies of the positive kind."

HISTORICAL.

THE ILLUSTRATED ADVERTISEMENT.

EVERY advertiser is ready to admit the advantages of illustrated advertisements, but few go beyond seeing that their advertisements are illustrated. It is one thing to illustrate an advertisement, quite another to illustrate it effectively. Some advertisers seem to run away with the idea that they must be eccentric in their illustrating to be convincing. Nothing could be further from the truth. If an advertisement is illustrated, the illustration should bear a distinct relation to the subject-matter of the advertisement, and should form

good photograph; and it is this fact, as much as anything else, that has led to the rapid advance of photography in advertising.

Already in America and here, photographers are devoting themselves solely to picture-making for advertising, and with far better financial results than they could hope to obtain from the regular

Example No. 1. A Repulsive Advertisement.

an integral part of it. It is all very well hitting on a catchphrase and illustrating it *à la* Catesby or the Lamson Paragon Co., but there is always the danger of the illustration and the catch-line being all of the advertisement that is noticed. When he "cuts the cackle and comes to the horses" the reader jibs.

To our mind, the illustration to an advertisement should, if possible, show the article advertised in use in some way or another. For instance, a maker of braces might show a man, *minus* coat and vest, on a ladder painting a wall, and leaning over to reach an out-of-the-way corner. The absence of strain from the braces he is wearing would be apparent to the most casual observer. Again, a gun-maker could arrange a picture of a sportsman drawing a bead on a bird, the surroundings, of course, being in harmony.

The Photograph.

For illustrations such as these, the average artist is entirely out of court. His sketches lack the vivacity and go that are afforded by a

Example No. 2. By Geo. Crook, M.P.S., Southport.

portrait gallery. Once the picture is secured, the artist, of course, is called in to work it up and to provide it with an appropriate dress in the way of border, lettering, etc., and the combined production gives far more satisfaction to the advertiser, and produces far better results than the mere line illustration to which we have so long been accustomed.

In this branch of publicity, as in all others for that matter, the utmost care has to be exercised to prevent a good conception being spoiled in the execution. We have, for the sake of example, selected three advertisements which owe their origin to photography, and which we can best classify as bad, good, and excellent.

The Repulsive Advertisement.

For the first we take the advertisement of an American house for a preparation of theirs for the relief of excessive perspiration. Could anything possibly be in worse taste? We have seen some bad specimens of advertising, but, for downright repulsiveness, we think this effort would be hard to beat. From a technical point of view, the photograph is, of course, good, and the meaning clearly conveyed, but we trust such realistic advertising will remain in the land of its birth. It has nothing to commend it, and its business-producing capacity is open to very serious doubt. It is degrading to photography to make use of it in such a way.

Pitfalls in Advertisement Photography.

For the second class, we have taken a card that is being sent out by Mr. Geo. Crook, chemist, of Southport, to push a new brand of soap he is handling. Here, to our mind, the idea is very good, and the result is a decided improvement on the average effort in this direction. The boy is the right age to use as an illustration for the article, and his holding out the cake of soap draws attention to that straight away. With much that is so good, it is a great pity some little defects were allowed to creep in to mar the whole. In the first place, an acolyte is scarcely likely to be wearing a monk's cowl, and, if he were, it is perfectly certain he would not have the neck thrown open sufficiently to show that he is wearing a fashionable collar and tie. In the second place, the fact of the boy being seated on a rather unlikely chair, before an unlikely table, detracts from the advertisement point of view. We would suggest that Mr. Crook would find it made a much more realistic illustration, and a better advertisement, if the chair and table were done away with, the box of soap stood on the floor, and the boy—wearing a chorister's surplice—held out the cake of soap a little less shyly.

Force in the Photographic Design.

The third illustration we consider distinctly good; it clearly conveys the advertiser's meaning and carries conviction. The clenched fist, the wrinkled forehead, all tell their tale of something forgotten, and one instinctively turns to the text to find out what it is. Here the introduction of the article advertised would, of course, have been ridiculous, but with such an effective illustration one could safely rely on the subject-matter being read.

In conclusion, we would suggest to advertisers that when deciding

to use illustrated advertisements, photography should have first claim on their consideration. The result is bound to be more satisfactory than the crude drawings which in many instances have passed good for illustrations. For the embellishment of booklets, catalogues, etc., photography stands pre-eminent, the introduction of a few pic-

Example No. 3. A Strong Photographic "Ad."

tures of the advertiser's business premises and stock-in-trade carrying far more weight than yards of written explanation.

[For permission to use the above article we are indebted to the "British Advertiser," in which it first appeared, and to the photographers who illustrate it. A note of certain offers which the "British Advertiser" is making to photographers appears elsewhere in this issue.—Eds., B.J.P.]

PHOTOGRAPHING LEAPING FISHES.*

A NUMBER of years ago I began to experiment with the camera to obtain photographs of leaping fishes, but always with indifferent success. The most difficult game appeared to be the large California flying fish, *Exocoetus californiensis*, which from the middle of May is a feature of the Santa Catalina channel, appearing in large schools and remaining all summer to deposit spawn in the bays of the islands. I made my first attempt from the bow of a steamer. I secured a position at the porthole in the bow, and while it was impossible to aim the Kodak with any certainty I snapped it at a number of fishes, hoping accidentally to take them; but the plates invariably developed blank; the flying fish had passed out of the field before I pressed the button.

Flying Fish.

Later I made the attempt from a small launch, with more or less amusing results. I sat on an elevated deck, so that I could command the field, and held a large Kodak ready for the fray. The first flying fish came directly towards the boat, passing within a short distance of me—in fact, so near that I moved to avoid it. Another fier struck

the boat; and on another occasion a fish almost unbalanced me, striking my neck; but this was at dusk. In none of these attempts was I successful, for it requires some skill to face a heavy flying fish, coming like a shot, with a camera and to dodge it at the right time. I had equally unsatisfactory results in attempting to photograph the tuna.

A Gun Camera.

In my attempts to photograph the tarpon I was also unsuccessful. I forced the fish to leap so close to the boat that they appeared to be coming aboard; but the sight was always so wonderful, that though I held the Kodak between my knees and had formulated an elaborate plan to pass my rod to the boatman on the jump and use the Kodak, it was always a failure. When the splendid fish rose into the air, I forgot the camera until too late. These more or less humorous adventures have probably befallen others who, not being expert photographers, will welcome a device which experiment has demonstrated, renders it an easy matter to photograph fishes of all kinds or indeed any animal in the air. It is literally a gun camera, devised by an ardent tarpon angler, Dr. W. H. Howe, of the city of Mexico.

* An article in the "Scientific American."

Dr. Howe spends a part of each winter at Tampico, where the tarpon appears to winter, and as the fishes are high jumpers and were in smooth water near shore he began to experiment along various lines, resulting in a gun camera which solved the question. The splendid tarpon, the "silver king," was caught in the very act and shown in various positions in the air, making a valuable addition to the angler's store and explaining many hitherto little understood features of tarpon leaping. The appliance of Dr. Howe is made up of a gun stock and a 4 x 5 Kodak, the latter being fitted into the stock so that the shutter and opening will be on a line with the sight. The shutter is connected with the trigger by a line, or wire, and to all intents and purposes the affair is a gun and used as such from the shoulder. The pictures were taken in the angler's boat, or from a second boat, the fisherman shouting a warning at the strike, whereupon the man with the gun camera rose, held it in the position of ready, and as the tarpon cleared the water in its initial leap raised it to the shoulder, aimed, and pulled the trigger or shutter. Dr. Howe's films show how excellent are the results, the tarpon being seen in every phase of leaping. With this appliance the flying fishes and tuna could be taken with comparative ease, while for birds on the wing the appliance would appear to have many advantages.

Combination Printing.

The attempts to secure animals in action, especially the difficult feat of taking fishes, have resulted in a variety of pictures not inappropriately called "false photography"; in that no deception is intended, an explanation is given. The picture is as perfect as though

the fish had been caught in the beautiful leap which has made the tuna famous; but the picture is merely the clever manipulation of the photographer, and when explained and understood by the reader becomes a rational and legitimate method of illustrating. In this instance the photographer took a large plate view of a section near Avalon Bay, noted as a scene of the tuna's leaps. Then a fish was posed and photographed, this being cut out of the photograph and pasted upon the proper background by an expert who had observed hundreds of leaping tunas; then the result was photo-engraved, giving a picture of a leaping fish which would be considered from nature by two-thirds of those who saw it. The picture, so far as position, height, etc., is concerned, may be said to be as natural as life, and indeed, was not modelled from memory, but from a real photograph of a tuna taken a long distance away, yet showing the exact position.

The gun camera will provide a valuable field for sportsmen and naturalists. The leap of the salmon, that of the mullet, the stupendous jumps of the whip ray, which I have observed clear remarkable distances in the Aransas region of Texas, the erratic jumping of the ten-pounder, will afford interesting subjects. The camera has entered many fields, but there are scores of forms which have yet to be taken in action. The many soaring animals, as the so-called flying lizard or draco, could be easily caught with this gun, as well as the flying squirrel in its downward rush. The bat has never been shown upon the wing, and at twilight could possibly be caught; indeed, this interesting plaything opens a new field.

CHARLES F. HOLDER.

PRACTICAL HINTS ON RETOUCHING.

[A Paper read before the Photographic Society of New South Wales.*]

Outfit.

FIRSTLY as to outfit. It is not elaborate nor expensive:—A desk such as may be obtained at any photographic warehouse; a couple of pencils, Koh-i-nor H.B. and H., or a box of Hardtmuth No. 3 refills and holder; a spotting brush, No. 1 Winsor and Newton sable (get a good one, they spring to a point better than camel hair); some colour for spotting (crimson lake, half-cake); a small piece of opal plate for a palette; fine sand-paper for sharpening pencils; a couple of knives for scraping the films, one small and fine for removing dark spots, stray hairs, spotty, patchy bits of light, the other larger for broader surfaces (the larger one may be got at the dealer's, but the smaller one is best made out of a large-size tailor's needle; break the point off about a quarter of an inch, then grind down on two sides and the point to an angle of, say, 45 degrees, put into a wooden handle, leaving about three-quarters of an inch of metal showing), and an oil-stone for sharpening the knives. A good finishing strop is made by cutting a piece of leather, say, 6 in. by 2 in., and gluing it on to a strip of wood. Rub some oil into it, then sprinkle it all over evenly with emery powder; rub it well into the leather with the handle of an old table-knife; use the strop frequently to keep a fine, keen edge. It is no use trying to cut on a negative with a dull knife.

The Medium.

As to medium. The beginner, if he wishes, may make his own, getting powdered resin and turpentine, about equal quantities, mixing and warming gently till the resin is dissolved, and thinning down with more turps as desired. If it works too hard, add a drop or two of castor oil, or oil of lavender.

Lastly, a bottle of turps and some old linen rag, free from lint or cotton wool, are required.

Sharpening the Pencils.

Cut the wood away about two inches; take care not to cut the lead. Get a bit of sand-paper about three inches square; fold it in two, rough surface inwards, hold it between the finger and thumb of the left hand; place the lead point in the sand-paper, and, gently squeezing with the finger and thumb, draw rapidly backward and forward, giving a turn to right and left at the same time. You ought to have a point as fine and round as a needle.

Commencing Work—the Knife.

When ready to start, place the negative on the desk and examine carefully for such marks as may have to be taken away with the knife if it is in a "view." There may be too many spotty high-lights in the foreground; take these down with a gradual scraping over the part, somewhat in the manner of taking out an ink-blot with a knife on paper, remembering always that it is well to hasten slowly when cutting, because getting it off roughly, or with jagged edges, only means more work to correct with the lead and brush later on.

Applying Medium.

When all the "dense" marks are removed, place a small drop of medium on the film, then, taking a piece of rag, place it over the end of the finger, moisten it slightly with turpentine, and rub the whole surface of the negative. There should be no trace of medium showing, but, for most of the softer and finer works, it gives enough "grip" to enable you to take them out with the softer pencil. Should there be parts requiring more work, e.g., where much scraping has been done, apply a drop of medium, and rub it over the part with a piece of rag or cotton wool (the wool made into a hard pad about the size of a hazel nut), so as to just cover those parts to be worked on. If, after working with the pencil, you find it will not "take" sufficiently, finish with the spotting brush, and colour, stippling evenly. Should some of the working show too strongly, reduce by stippling with the

* We are indebted to our contemporary the "Australian Photographic Journal" for the report of this lecture.—Eds., B.J.P.

point of the smaller knife, and so keep on using knife and brush correcting each other until it is done so that it will not show in the printing. A little practice will enable you to fill gaps and holes in negatives quite easily.

Portrait Negatives.

For a portrait, unless the background is much marked or spotted, you need only apply the medium so that it covers the head and about half an inch or so wider, for it frequently happens that a picture may be much improved by taking out stray bits of hair, either with the knife or pencil. Also medium the hands, if showing.

In retouching portraits it is not how much you may do to a negative, but how little; not crowding the lead on, but placing it just where the least work will give the most effect.

Acquiring a Touch.

There is no particular kind of stroke to learn that will enable you to become a retoucher, but just where there is a line-freckle or mark, or whatever the defect may be, carefully fill that part so that it comes even with the surrounding part, and, that kept up gradually, you will find that you are getting a nice "grain" in retouching "talk," or stipple, as others call it. During the progress of your work occasionally look at your negative reversed; sitting well back, take a general survey of it, and, where the work looks patchy, blend them into each other. Let all the cutting be done to the negatives before the medium is applied.

Should the work not be satisfactory, it can easily be taken off by rubbing over with the rag and a little turpentine and fresh medium applied, and in case a negative requires a great deal of work, say, a big head (freckled), when you cannot get any more on the film, varnish the negative, and, when quite cold, apply the medium as before and continue the work.

Remedying Negatives.

It sometimes happens that a negative has thin shadows—though full of detail and hard lights, the shadows being too black by the time the lights are printed up. Rub some crimson lake on the palette, getting it pretty thick. Put the negative on the desk, glass side towards you. Moisten the tip of the finger with the lips and rub on to the colour, and dab on to the shadows to be held back; repeat until the whole is evenly coloured. Small spaces to be coloured, such as hands in shadow, shadows under brows, etc., treat in the same way. Do not mind going over them wide. You can correct the outline afterwards with the knife.

It might be mentioned that in addition to the articles required for retouching the beginner lay in a good stock of "patience." That and practice rubbed well in will soon show good results. Do not be disheartened if the first attempts look scratchy; rub them off and try again.

JAMES H. GAMBLE.

THE OPTICAL CONVENTION.

On Tuesday next, May 30th, the Optical Convention opens its session at the Northampton Institute. Its chief activities have already been noted in these columns, but we can now outline the leading features of the exhibition held in connection with the Convention. The catalogue of the latter will be a particularly valuable work of reference.

The instruments are arranged in classes; each class is preceded by a short introduction, giving a general description of the instruments included in the class. Special attention has been paid to convenience of reference. In addition to the more strictly optical instruments, many other types of scientific instruments are included. Thus, one class is devoted to meteorological instruments and thermometers, another to laboratory instruments; mathematical and drawing instruments, and calculating appliances are also shown. Under Class 1, "Tools and Materials," is to be found a selection of optical glass, by the great glass-making and lighthouse firm—Messrs. Chance Bros., of Birmingham. Messrs. Powell and Sons, of the Whitefriars Glass

Works, have an interesting exhibit of thermometer glass. Messrs. Geo. Culver, and other firms, show tools and processes of manufacture. Class 2, "Simple Optical Elements," includes an exhibit of accurate work in prisms and plates, by Messrs. Hilger, and diffraction gratings, by Lord Blythswood. The two most important classes in which the excellence of the English work is most apparent are, perhaps, those of surveying instruments and microscopes; these are both well represented, and the exhibits will be found of special interest.

"Projection Apparatus" includes an exhibit, in action, of a complete lighthouse apparatus of the fourth order, by Messrs. Chance Bros. The exhibits of optical lanterns, cinematograph apparatus, etc., are very complete.

Other classes which may be mentioned are "Telescopes and Binoculars," "Photographic Apparatus," and "Photometric Apparatus." In the class devoted to optical measuring instruments some admirable work is exhibited by the Cambridge Scientific Instrument Co., and by Messrs. Hilger.

Photo-Mechanical Notes.

Colouring Photographs for the Three-colour Process.

It frequently happens that in colouring bromides and silver prints the artist has great difficulty in getting the water colour to take to the paper. "Camera Craft," in its issue of May, page 307, recommends the following methods:—For bromide paper prepare the following solution:—

Purified oxgall	30 grs.	30 grs.
Glacial acetic acid	30 minims	30 c. c.
Distilled water	3½ oz.	350 c. c.
Methylated spirit	1½ oz.	150 c. c.

Shake till dissolved, filter, paint over the print, and allow surface to get dry, and mix the paints with a drop or two of this solution also.

When it is desired to tint or touch up a glossy silver print with water-colours, the resistance offered by the shiny surface can be overcome by treating it with the following solution:—

Albumen	6 drachms
Glycerine	1½ drachms
Ammonium carbonate	15 grains
Ammonia, .880	1 drop
Water	1½ drachms

First thoroughly incorporate the albumen with the water, and then add the other ingredients. If oil-colours are to be used, the print should be coated with a mixture of gelatine and gum arabic.

A Loan Process Exhibition at Manchester.

It is understood that the Board of Education is to co-operate with the Manchester Education Committee in securing for exhibition in Manchester the loan exhibit of process engravings now on view at South Kensington. The exhibition, as we have already intimated, comprises an historic series of examples of process engraving, including photogravure, photo-lithography, and kindred processes of reproduction by means of photography, including half-tone colour printing. All the most expert operators in the chief countries of Europe, and also the United States of America and Japan, have contributed.

The Newspaper Half-Tone.

The wickedness of the half-tone portrait as it is frequently printed in the daily Press is brought before us by a cutting from the Belfast "Evening Telegraph," in which we find a "portrait" of Mr. H. C. Shelley, who is at present in Belfast lecturing at the Kodak exhibition. Mr. Shelley has our sincere sympathies. In extenuation of the half-tone reproduction, some blame may perhaps be attached to the original photograph, but we cannot imagine that Mr. Shelley would pass to the engraver a proof showing him as the dark-visaged being that the printed newspaper has given us.

Exhibitions.

MARINE PHOTOGRAPHY AND WAVE STUDIES AT THE R.P.S.

If it cannot be fully claimed that Mr. Mortimer has discovered an absolutely new outlet for æsthetic photography, he has certainly hit upon a form of pictorial work which affords a most fascinating amount and variety of dangerous adventure and of physical endurance as should commend the practice to every muscular "plain-air-ist," who would rather that his pictorialisms were derived from struggles with nature than from the realisation of tonal abstracts. It is evidently because the photographer has lived by these gale-lashed shores, watching, waiting, wrestling, and, above all, observing and memorising how the frenzied breakers and the raging surf impress the sight and affect the recollection, that the collection of Mr. F. J. Mortimer's "Marine Photography and Wave Studies," at the Royal Photographic Society, combine, with the technical and artistic merits, an unusually large proportion of tonal veracity.

Looking at the collection as a whole, the chief impression is that the photographer has been fortunate in the colour of most of the prints, the tones being of a cool brown, in some instances verging upon olive, and in some prints passing into shadows of a full brown-black. They are all enlargements from $\frac{1}{4}$ or $\frac{1}{2}$ -plate, up to about 30 by 20 and larger, upon paper mostly with a rough drawing paper grain. As regards the delicacy of half-tone present, this must be ascribed to a skilful correlation of exposure and development, both of negative and of positive. Take, for instance, No. 33 ("In the Height of the Storm"), a picture of seething surf and spume. It has hardly an absolutely white spot in it, and yet, although everywhere full of modulation, the foam of the breakers and the froth of the under-tow, stand out in well defined masses of light. The usual trouble with longshore marines—a horizon line which cuts the picture in two—has in most cases been avoided by taking a low point of view, so that wave crests, clouds of spray, and detached groups of rock, hide or break up the junction of sea and sky. That the delicate tracery of wind-blown spray and mountains of water bursting into myriads of diamonds should be adequately delineated, the employment of a low tone sky was necessary. In most instances this has been realised with considerable judgment and skill. If occasionally, as in No. 24 ("A Study in Black and White"), the sky has been over-corrected, or by some other means rendered darker than one would wish, it must be set to the exhibitor's credit that in the majority of instances the luminosity of cloudland has been well preserved or adequately suggested, and has been just sufficiently subordinated as to act as a foil for the white fringed waters and clouds of spray. In criticising such skies it should be well remembered that their main function is to play the part of a background, wherefore it should, as a rule, suffice that the beholder is not unaware that the dark and lowering heavens are torn into ragged shreds by the rough onslaughts of a winter gale; he should not—and does not—need to be curious as to their precise conformation or relative tonality, for his mind should be preoccupied, and his eyes fixed upon, the howling wastes of mighty waters, the white-capped vanguards of Neptune, the sea horses which imagination pictures as drawing his car, and other protean splendours of the sea, "in fine frenzy rolling" on to the shore and thundering against the granite fastnesses of the far western Scillies.

Some of the photographs depict a comparative placidity of water and brightness of sky, as in No. 49, where the sun seems to throw golden tracery upon the "Majestic Main." In this, although there is some disconnection of interest between the upper and lower portions of the print, the general breadth of rendering, added to the effective juxtaposition of strong light in the water, with the deep shadows of

a picturesque billow, which forms the chief object, brings the eye to rest at the centre of interest.

It may be well to point out that most of the prints are composed upon what is termed the diagonal plan. That is to say, the general lines of the waves run into the picture, so that if prolonged they would meet at a point towards the left or right. This disposition generally involves the provision of some strong object, especially where the prevailing lines are inclined to lead the eye to look outside the boundaries of the print. Cliffs, rocks, or breaking waters will, in most instances, be found supplying the needful support to the composition. Occasionally concentration of interest and balance of line have been attained by means of a strongly accentuated scheme of cloud lighting, as in No. 25 ("Great Ocean!"), in which the line of the wave crests running diagonally across the picture has been balanced by the line of light in the clouds, thus effectually preventing the interest from running out of the picture.

Amateurs—and also those professionals whose scope of action is not bounded by the studio—should certainly see the collection, for, in the first place, they will acquire a mental standard of excellence to work up to, and also they will realise that fortuitous photography has seen its best days. For, in Mr. Mortimer's case, one cannot but recognise that he has, in the first place, known what he wanted to accomplish; and that in the second he has spared neither time, trouble, nor æsthetic striving in realising his aims, which I assume to be the depiction of his subjects, under rare and imposing circumstances, with a nicely balanced proportion of truth to nature, and of refinement of composition. Although the threescore prints have been made as an exposition of the artistic possibilities of the camera, and are therefore in no wise to be regarded in the same category as what are known as artist's studies, painters whose subjects are akin to those of Mr. Mortimer's would be well advised to pay a visit to the collection; indeed, every lover of the sea coast will find a fund of pleasure in the impressive moments which have been captured with so much skill and rendered with not less taste. The exhibition remains open—at the rooms of the Royal Photographic Society, 66, Russell Square—until June 17; admission, between 10 and 6, being free to all comers on production of visiting card or by introduction by a member.

HECTOR MACLEAN, F.R.P.S.

ALPINE PHOTOGRAPHY AT THE ALPINE CLUB.

An exhibition of photographs taken by members of the Alpine Club is being held at the Club Rooms, 23, Savile Row, W. Apart from the undoubted interest these representations of vast expanses of snow-clad mountain scenery must have to mountaineers, the pictorial qualities which are strongly in evidence in many of the exhibits will appeal to every visitor who is not a climber. Even regarded as merely photographs of snow and ice, the photographer will find much to interest and instruct him, although, owing doubtless to the extraordinary atmospheric conditions that prevail at the high altitude where most of the photographs were obtained, there is in most instances a lack of what the pictorial worker would describe as atmospheric diffusion and recession of planes.

It must not be supposed, however, that the pictures do not rise beyond the topographical stage. From the point of view of the members of the club this would probably be of as much importance as a pictorial rendering, and it is therefore all the more worthy of note that the pictorial view has not been sacrificed to the mere record of fact. The unavoidable lack of scale is, nevertheless, likely to be a deterrent to the full enjoyment of a contemplation of the photographs of these instances of nature's grandeur and immensity, and it will probably need a mountaineer to fully realize the extent of the locality depicted. The pictures are, in many instances, helped pictorially by the wonderful cloud forms portrayed. The contributions by H. Priestman (57 and 63), Charles Lord ("Daybreak

from the Riffelberg"), Miss E. Venables ("Sunset over the Brévent" and "Evening Clouds over the Arolla Valley"), and others, are particularly notable in this respect; in fact, the two pictures by Miss Venables approach the impressionistic in their weirdness.

From the pictorial standpoint, also, the works of Professor J. Norman Collie are noteworthy. The prints are of beautiful quality, and in addition to being fine Alpine photographs, are pictures that would compare favourably with the productions of any other avowed pictorial user of the camera. A very fine contribution, both pictorially and technically, is No. 107 ("The Matterhorn from Breuil"), by C. Thurston Holland. This is a carbon print of important size and of superlative quality. The curious lack of atmosphere observable in most Alpine photographs, whereby the extreme distant mountain peaks are rendered as clean cut and clear as the immediate foreground, is very noticeable in this picture, but serves to render it all the more impressive.

Two delightful little studies of the Upper Grindelwald Glacier, in green carbon, by Miss C. Ellis, are excellent specimens of good, clean, technical work, and it is noteworthy that many of the good things on the walls are contributed by ladies. Several series of small photographs framed in groups are on view, and they are also of high merit, and show that when dealing with such a subject, wherein it is impossible to even approximate the size of the original, the smaller photographs, if treated sympathetically, score almost as much as the larger specimens.

Strange to say, telephotography does not find extensive employment by the Alpine photographer, if the present show can be taken as a criterion. There are certainly one or two examples on view, but of no great importance, and it can only be assumed that the hardy member of the Alpine Club prefers to tackle his game at close quarters, and as "the climb's the thing," the tele-attachment and its attendant troubles are left at home. In fact, it is to be assumed that in most instances the photographs obtained are to be regarded merely as incidents to a climb, and not its primary cause; but they should not, on that account, lose any of their value as instructive factors for other photographers. No opportunity of visiting the exhibition, which closes on May 31, should therefore be lost.

THE LEEK PHOTOGRAPHIC SOCIETY is holding an exhibition in the North Cabinet Gallery of the Nicholson Institute, Leek. Invitations in the shape of dainty little bromide prints were issued for a private view on Thursday; and the exhibition will be open daily until next Thursday. As the price of admission is the popular one of nothing, with a catalogue at the same figure, it is to be hoped the townspeople will appreciate the efforts of the society.

FORTHCOMING EXHIBITIONS.

May 10 to June 19.—Salon of the Photo Club de Paris. Secretary, Paul Bourgeois, 44, Rue des Mathurins, Paris.

May 30-June 1.—Students' Art Club, St. Leonards-on-Sea Photographic Section. Hon. Secretary, Miss Watson, "Deverell Hurst," De Cham Avenue, St. Leonards-on-Sea.

July 4 to August 12.—Northern Photographic Exhibition. Secretary, F. G. Issot, 62, Compton Road, Harehills, Leeds.

July 15-25.—Sixth International Salon Association Belge de Photographie, Liège. Secretary, Mr. Servais, 34, Rue du Saint-Esprit, Liège.

September.—Royal Photographic Society, New Gallery, Regent Street, London, W. Secretary, J. McIntosh, 66, Russell Square, London, W.C.

October 28-November 4.—Sheffield Photographic Society. Joint Hon. Secretaries, J. W. Charlesworth, 1 Joshua Road, Sheffield, and James W. Wright, 62, Vale Road, Sheffield.

November 14, 15, 16.—Ipswich Camera Club. Hon. Sec., R. H. Sutton, 37, Henley Road, Ipswich.

November 21-25.—Southampton Camera Club. Hon. Secretary, S. G. Kimber, Oakdene, Highfield, Southampton.

December 1-6.—Hove Camera Club. Hon. Secretary, A. R. Sargeant, 55, The Drive, Hove.

December 12-20.—Southsea Photographic Society. Hon. Secretary, F. J. Lawton, 5, Pembroke Road, Portsmouth.

March 3-10, 1906.—South London Photographic Society. Hon. Sec., H. Creighton Beckett, 44, Edith Road, Peckham, S.E.

FORTHCOMING COMPETITION.

September.—Kodak. £400 in prizes for results on Kodak products. Kodak Ltd., 57-61, Clerkenwell Road, London, E.C.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

The following applications for Patents were made between May 8 and 13:—

DARK-ROOM LAMPS.—No. 9,661. Improvements in photographic dark-room lamps. Frederick Thomas Parsons, 27, Southdean Gardens, Wimbledon Park Road, London.

PAPER.—No. 9,667. Improvement in the manufacture of photographic paper. Edouard Mallet, Birkbeck Bank Chambers, Southampton Buildings, Chancery Lane, London.

STAMP PHOTOGRAPHS.—No. 9,729. Improved repeating back for taking midget and stamp photographs. George Thomas Bayley, 3, Union Street, East Stonehouse, Devon.

WASHING PAPERS.—No. 9,749. Apparatus for the washing of photographic papers. James Hazell and Albert James Chapman, 107, Mansfield Street, Kingsland Road, London.

DEVELOPING, ETC.—No. 9,806. Improved apparatus for developing and fixing photographic plates. Edward Rosell Petrie, Fife House, Kingston-on-Thames.

CHEMICALS.—No. 9,870. Improvements in treating soluble chemicals for photographic and other use. William Fraser Claughton Kelly, and John Arthur Bentham, 7, Southampton Buildings, Chancery Lane, London.

COMPLETE SPECIFICATIONS ACCEPTED.

Specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

PIGMENT PAPER.—No. 23,766, 1904. In place of the fairly thick layer of pigmented gelatine, with its alleged defects of slow drying and difficult stripping, the original paper or sheet of celluloid or tissue base is provided, before the addition of the pigmented gelatine, with a layer of gum arabic or similar substance soluble in cold or warm water, this layer serving as an insulating medium. These substances, moreover, have in combination with bichromate salts a considerably smaller sensibility to light than the pigmented gelatine layer proper, producing the pictures. In the case of pigment paper or tissue thus prepared, the original paper base, after the copy has been transferred in a well-known manner in cold water on to the developing paper, can be easily removed in the air, that is, when taken out of the water, without or with the help of warm water. As a further advantage of this pigment paper, it may be mentioned

that it can be manufactured without the safety edge on the negative which has hitherto been necessary. Albert Hochheimer, Feldkirchen, Munich, Germany.

FILM CHANGERS.—No. 14,329, 1904. A device for a packet in which a number of films can be brought up for exposure and then removed. In the figure, *a* is the back of the packet and *b* that end of the same through a slit in which the ends *c* of the bands or tabs are presented for enabling the sensitive films or plates to be transferred in succession from exposure position at front of the packet to storage position at rear thereof, the transfer being effected by pulling on the respective tabs or bands, which are connected to the respective films or plates and pass around a guide or roller situated usually at the end of the packet opposite

to the end *b*. After the transfer of a film or plate has been effected, the projecting portion of the band or tab may be torn off. In order to enable the films or plates which have been thus transferred to the rear of the packet to be withdrawn for development or otherwise without disturbing the remainder of the contents of the packet, a door *d* is provided, extending across the back *a* of the packet towards the end thereof opposite to the end *b*, this door being hinged to the back as at *e*, and spring-pressed and padded or otherwise adapted to normally maintain a light-tight closure. In the drawing, *f* represents a film or plate which, having been transferred from the front to the rear of the packet by means of the band or tab *c* (shown as having been subsequently torn off), is in process of being withdrawn through the open door *d*. Newton Livingstone Scott, 18, Ironmonger Lane, London, E.C.

AUSTIN-EDWARDS Monthly Film Negative Competition.—The prize camera for current month has been awarded to Miss Gill, Compton, near Guildford, Surrey, for her negative "Doorway of a Memorial Chapel."

New Books.

"The Year Book of Photography and Amateurs' Guide." 1905.

Edited by P. R. Salmon, F.R.P.S. London: "The Photographic News" Office. 1s.

Quite a series of monographs on practical subjects appears in the text pages of the issue of the "Year Book" just published. The editorial is on "Platinotype Printing." E. J. Wall follows with an historical review of platinotype printing and a treatise on the preparation of the paper, the first of which is valuable for its copious references to the scattered literature of the subject; whilst the notes on manufacture appeal, we suppose, to the curious class of amateur who does not know a good thing when it is on the market. "Iron Printing Processes" other than platinotype, and "Press Photography," excellently illustrated, are two further articles with their direct appeal to the amateur. And lastly comes Mr. H. W. Bennett, overflowing with arguments, contentions, objections, and advice anent pictorial composition, all emphasised and explained by the aid of some thirty sketches. Altogether, quite a budget of good reading for our amateur friends, even supposing there were no sections on tables and formulæ, novelties in apparatus, etc., to which, as a matter of fact, some 250 of the total 600 odd pages are devoted.

The Photographic "Red Book." Published by The Affiliation of Photographic Societies, 66, Russell Square, London, W.C. Price 1d.

The Affiliation of Photographic Societies' Annual for 1905, familiarly known as the "Red Book," has reached us, and the first thing we note is its increased bulk. An inspection reveals the cause of this to be the inclusion of eight half-price tickets for the annual exhibition at the New Gallery, and we can congratulate the executive on having hit on this excellent method of doing away with the everlasting bother that accompanied the previous plan adopted. Sending batches of half-price tickets to secretaries of societies, on sale or return, seemed simple enough in theory, but when the day of reckoning arrived we more than suspect that the collection of the unsold tickets, and the sixpences derived from the sale of others, involved more trouble and expense than appeared on the surface. It remains to be seen how the new system will work. Briefly it is this: The "Red Book" can only be obtained from the secretaries of the various affiliated societies, who, of course, will supply only to members. The reduced-price tickets are bound up in the book, and are perforated for easy removal. The presentation of one of these tickets and sixpence at the New Gallery during the exhibition will admit bearer. The tickets that are not used can be thrown away afterwards. They are no further use after the end of October. The number of tickets handed in at the door will show the extent to which they are used, and no further trouble devolves on the Secretary to collect those not used, or their value from the local secretaries. The only possible exception that can be taken to the new plan is that when giving a ticket to a friend it has to be explained that sixpence is necessary as well as the pass before admittance is granted, whereas in the old system the ticket gave admission without any additional money payment at the doors, and the local secretary, when settling up, paid the difference.

The general plan of the "Red Book" is similar to that of the previous editions. The advantages and privileges of the affiliation are fully set out. Rules for judging, interchange of lectures, and a catalogue of the loan collection are included.

The list of places in England to photograph appears to have been extended and amplified, and should form in the future, as it has in the past, a most useful feature. The places of interest in London and district at which the presentation of the "Red Book" gives

admission is also very complete, and indicates very markedly one of the chief points of utility of the affiliation. A full list of the affiliated societies, which have increased in numbers considerably during the past year or two, forms the bulk of the book, and the information as to their officers, headquarters, dark rooms and accommodation, etc., will be appreciated by the photographer on tour who is either a member of the R.P.S. or of another affiliated society. One penny per copy, which is the small charge made this year, will not be begrudged by the members of the affiliation.

"The Photographer's Peerless Note Book." London: Houghtons, Limited, and Charles Letts and Co. 1s.

The 1905 edition of this very compact exposure record has been improved by an exposure calculator which gives, without any arithmetical operation, exposures of any subject, with any stop on any plate. The "Note Book" contains also a number of hints on exposure and development, and a list of dark rooms in the United Kingdom.

"The Book of Photography." Edited by Paul N. Hasluck. London: Cassell and Co. 10s. 6d.

An English book treating of photography from first to last is certainly a volume for which there is an empty place at the present time. Our photographic literature in this country, like Mr. Gilbert's gay young sorter, is "chopped particularly small." A few volumes, such as Sir William Abney's "Instruction in Photography" or Mr. Brothers' "Photography," aim at comprehensiveness, but the information consulted by the majority is disseminated through a hundred or so small books. Messrs. Cassell occupy the breach with a handsome production, externally well fitted for presentation to any one interested in photography. Naturally its contents are our chief interest. And we find that the editor has judiciously steered along a middle course between the Scylla of academism and the Charydis of beginners' piffle and "shoppy" talk. He supplies information, on pretty nearly every photographic subject, which any one already slightly acquainted with photography would be likely to want. He is not encyclopædic, and he does not attempt historical treatment of special subjects. In short, the volume is for the photographer of a few years' standing, who will find its pages a constant help. The student who has to verify even a minor reference will still need his Eder's "Handbuch" or Fabre's "Traité," but Messrs. Cassell's volume should satisfy the immensely larger class of readers who are less exacting in their demands, and require a volume more as a help in their practical work than for literary purposes. The "Book of Photography" is profusely illustrated and supplied with supplemental plates, and a very full index is not the least of its good features.

"A Souvenir of Weston-super-Mare" is published by the District Council of that holiday resort, and will be sent free on application. The souvenir is practically an illustrated guide to the vicinity.

"Lynton, Lynmouth, and the 'Lorna Doone' Country" is the subject of a new "Homeland" guide. (The Homeland Association, Ltd., 22, Bride Lane, Fleet Street, London, E.C., 6d.) The text of the book interweaves the stories of the Doones with a concise description of the country. There is an Ordnance map, and the volume is illustrated with a number of new photographs by Mr. J. A. C. Branfil.

A SECOND edition of that very useful shilling handbook, "Photographic Failures: Prevention and Cure," has just appeared from the press of Messrs. Dawbarn and Ward, Limited, 6, Farringdon Avenue, London, E.C. It preserves its character of a small encyclopædia of "petites misères," easy of consultation, and helped by the transparent negative charts, by which a very fair idea is gained of errors in exposure and development.

New Materials.

The "Helix" Film Washer. Sold by Kodak, Ltd., 57-61, Clerkenwell Road, London, E.C.

A very convenient washer, this, for users of roll-film. Its circular partitions provide for the insertion of a 12-exposure roll in two sections, and the inlet and outlet of the water are so arranged as to afford a free passage over the whole surface of the film. If

the film is cut up for development each negative is suspended in the water by a clip, and washing takes place in the same manner. The washer is made in about half a dozen sizes, and at prices from 5s. 6d.

Antique Mounts. Sold by Kodak, Ltd., 57-61, Clerkenwell Road, London, E.C.

A hand-made paper, of rough surface and in a choice of quiet colours, imparts a genuine refinement to these new mounts of Kodak, Ltd. They are supplied with a deckle edge in brown, grey, or green, each with a plate-marked space, circular or oblong, for the print. They are obtainable in 1s. packets in five sizes, from No. 1 F.P.K. to half-plate. Quite as tasteful and saleable a style of mount as we have seen for a long time.

RECEIVED. The "Three-Colour" plate for three negatives at a single exposure in an ordinary camera. (Dr. J. H. Smith and Co., Zürich; British agents, Penrose and Co., 109, Farringdon Road, London, E.C.).

THE Eastman Plate, rapid and extra rapid. The above plates, now placed upon the market by Kodak, Limited, will be noticed in due course.

CATALOGUES AND TRADE NOTICES.

"GLAZEIT."—A preparation sold under this name has been put on the market by Messrs. Wilkins and Co., of 14, Cape Hill, Birmingham. It is akin to formaline, and its function is to harden the surface of gelatin P.O.P. previous to squeegeeing on ferrotype, glass, or celluloid. The directions for use are, briefly, to place the prints to be treated in the "Glazeit" for fifteen minutes after fixing and washing. Then squeegee on to the plate or glass. When dry, they will fall off with a highly-glazed surface. The "Glazeit" may be used over and over again, and is not expensive. Messrs. W. Butcher and Sons, Camera House, Farringdon Street, E.C., are the wholesale agents.

UNDER the title of "Guide to the French Photographic Trade," a catalogue has been issued by the "Chambre Syndicale des Fabricants et Négociants de la Photographie," a body which is composed of the chief makers of and dealers in photographic material in France, and has M. L. Gaumont as its president. The list is arranged in alphabetical order of the members of the "Chambre," and is no doubt obtainable from the offices of the latter, 54, Rue Etienne-Marcel, Paris.

THE ELGE MONTHLY LIST.—We have received a small booklet from Messrs. L. Gaumont and Co., dealing with the Elge cinematograph films. It should prove useful to all interested in animated photography. A copy will be sent free on application to 22, 23, 25, and 27, Cecil Court, Charing Cross Road, London, W.C.

A COPY of Messrs. Erdmann and Schanz's new abridged catalogue of stereoscopic slides has been sent us. Under the name of "Binocular Realisticgraphs," an almost endless variety of subjects is presented, and in view of the high class of work usually produced by this firm, every possessor of a stereoscope should obtain a copy of the list. A postcard to 116, Bedford Hill, Balham, S.W., will secure one.

BRITISH FERROTYPED PLATES.—The following is the full list of sizes and prices in which these plates are supplied, and it will be seen that the quarter plate is put up in dozen packets at 2s. 6d., not 3s., as stated in our last issue:—14 in. by 10 in. (half dozen), 11s. 6d. per packet; 14 in. by 10 in. (one dozen), 20s.; 10 in. by 7 in. (half dozen), 6s. 6d.; 10 in. by 7 in. (one dozen), 10s. 6d.; half plates (half dozen), 2s. 6d.; half plates (one dozen), 4s. 6d.; 5 in. by 4 in. (half dozen), 2s.; 5 in. by 4 in. (one dozen), 3s. 6d.; quarter plates (half dozen), 1s. 6d.; quarter plates (one dozen), 2s. 6d.; $3\frac{1}{4}$ in. by $2\frac{3}{4}$ in. (half dozen), 1s.; $3\frac{1}{4}$ in. by $2\frac{3}{4}$ in. (one dozen), 1s. 6d.; $2\frac{1}{2}$ in. by 2 in. (one dozen), 1s. 2d.; $2\frac{1}{2}$ in. by 2 in. (three dozen), 3s.; Victoria size (100), 4s. 6d.

A NEW catalogue of apparatus specially adapted for taking and printing miniature photographs, and also for photographic buttons and stamps, has been sent us by the Executors of J. Billcliffe, camera manufacturers. The list is very complete, and a feature is made of fitting repeating backs for midget photographs to customers' own cameras. A variety of nearly thirty repeating backs for this purpose is given, and also the same number of frames for printing these small photographs, in addition to other apparatus. A copy of the list will be sent on application to Richmond Street, Boundary Lane, Manchester, S.W.

"VELOX" pictorial postcards, issued as an advertisement by Messrs. John J. Griffin and Sons, Limited, of 20-26, Sardinia Street, Lincoln's Inn Fields, are attractive in design, and should serve the purpose of still further impressing upon photographers the advantages of the popular gaslight paper. Samples of these cards will be sent post-free on application.

"THE Imperial Handbook," 1905, just issued for gratuitous distribution by the Imperial Dry Plate Company, Limited, Crickiewood, London, N.W., is this year given the form of an album of portraits of the world's rulers by leading photographers, who in almost every instance have made their negatives on "Imperial" plates.

A LIST of brass work and camera parts of all descriptions reaches us in a new issue from Messrs. George Mason and Son, Armley Grove Works, Leeds. The business is a special one with Messrs. Mason, and the list is pre-eminently useful whenever apparatus is to be put together or adapted. There are articles on the home-making of cameras, etc., but the firm also supplies the finished article.

BARGAINS in cameras and accessory apparatus are listed to the length of thirty pages in the latest monthly catalogue of the Tella Camera Company, 110, Shaftesbury Avenue, London, W., a firm which makes a specialty of weekly or monthly payments for new or second-hand apparatus. Customers' cameras are also taken in exchange, and the present occasion seems a favourable one for a rearrangement of one's outfit.

THE Busch anastigmat will be sold in future as the "Omnia," and a new series, $f/4.5$, has just been added.

A STRONG and neat case for unmounted prints is a new introduction of Kodak, Ltd. It accommodates a dozen prints, which are temporarily held by the turned-over edges of the leaves. Bound in green art vellum, with a metal clasp, this "pocket print case" costs 1s. or 1s. 3d., according to size.

A SAMPLE of "Rajar" P.O.P., as now issued in a mauve colour, reaches us from Rajar, Ltd., 119, High Holborn, London, W.C., and confirms us in the good opinion of this printing-out paper which we expressed on its first introduction.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

May.	Name of Society.	Subject.
27	Bowes Park Photo. Soc.	Excursion, Burnham Beeches.
29	Wallasey Amat. Photo. Soc.	"Bromide Toning," Mr. W. Hayes.
29	Southampton Camera Club	"With the Camera Club through Southampton." Professor F. J. C. Hearnshaw.
30	Birmingham Photo. Society.	Exhibition of Novelties in Apparatus.
30	Manchester Amat. Photo. Soc.	"Carbon Printing," Rev. H. W. Dick.
31	Everton Camera Club	Evening Outing, <i>re</i> Class 1 Competition.

NORTH MIDDLESEX PHOTOGRAPHIC SOCIETY.

MR. H. STUART lectured on the 17th inst. on "Carbon Printing." He recommended as a sensitising bath the formula worked out by Mr. H. W. Bennett:

Potassium bichromate	4 drms.
Citric acid	1 drms.
Water	25 oz.
Ammonia .880	about 3 drms.

in which the tissue can be left from one and a half to three minutes. It is then lightly squeezed into contact with glass or a ferrotype plate and the back wiped dry with a cloth. Tissue thus prepared is best used within three days, and in the meantime is kept under pressure. Printing is gauged by an actinometer, and the printed tissue is soaked in water until it becomes almost flat after having curled inwards. It is then lifted from the bath together with a piece of support (single transfer paper) which has been properly soaked in advance. These two pieces with the tissue uppermost are pressed into close contact, excess of moisture removed by wiping with a cloth, and the two placed between blotting boards or strawboards under a weight for from ten to twenty minutes. Mr. Stuart recommended that at the expiration of this time the sandwiched print be put into cold water and allowed to soak. This, he thought, assisted the stripping, and prevented possible insolubilisation. Water of a temperature of about 95 deg. will dissolve the gelatine, and after stripping, the temperature can be raised if it is found that the tissue has been fully or over-printed. A slight rinse in cold water, immersion in an alum bath, and again washing, completes the process.

Mr. Stuart gave a practical demonstration, which in his hands showed the advantage of a process whose permanence appealed to all his hearers. This lecture was an excellent sample of the instruction lectures delivered regularly before the North Middlesex. Any person desiring information as to forthcoming fixtures should apply to Mr. S. C. Puddy, 87, Crouch Hill, N.

CROYDON CAMERA CLUB.

ON Wednesday, the 17th inst., a series of criticisms by the well-known artist, Mr. F. M. Bennett, dealing with the collection of members' work which has occupied the walls of this Club for some little time, was read by the Hon. Sec. Mr. Bennett certainly did not err on the side of over-appreciation of the "art" of the camera, but his criticisms lost nothing in value on that account, and were extremely helpful to all concerned.

A discussion on "Orthochromatism," which had taken place a fortnight before, was resumed, and the President, Mr. W. H. Smith, showed a series of prints from a large coloured poster, the negatives being taken on ordinary plates, and colour-sensitive Wratten plates, with and without filters. The light employed was magnesium burnt in oxygen, generally supposed to be deficient in the yellow rays. The "ortho" plate and filter, however, gave a satisfactory rendering, including the yellows.

Mr. E. A. Salt showed a set of prints from negatives taken by daylight of a built-up model of coloured objects and foliage. With

reference to a statement made on a previous occasion, that a good many floral photographers invariably used ordinary plates, he had considerably overexposed a slow ordinary plate for the blues, to, so to speak, give the yellows a chance to come up, which they had signally failed to do. He therefore concluded that floral photography on ordinary plates was only possible so long as no sharp contrasts of colour existed. A "chromatic" plate without a filter showed distinct signs of improvement, and with a so-called ten-times screen a very good result was obtained, but the filter not being adjusted to the plate, over-correction of the yellows and yellow-green was observable. A "spectrum" plate with an "absolutus" filter gave a most satisfactory translation in monochrome. Mr. S. H. Wratten passed round a photograph of the spectrum, showing a wonderful range of sensitiveness. The negative was on a "Speed" plate, sensitised with Homocol by the bath method.

Mr. F. W. Hicks, whilst recognising the advantages of orthochromatic plates and filters for copying pictures, flowers, and the like, doubted whether much benefit was to be derived from their use in every-day landscape work. He had not found it so, and this view was largely shared by others present.

WEST HARTLEPOOL PHOTOGRAPHIC SOCIETY.—The annual meeting of this society was held on Wednesday of last week. The report submitted by the hon. secretary showed that the year has been a successful one. It was decided that the present committee and officials remain in office for the present, with the addition of Mr. F. Morley as joint treasurer.

Commercial & Legal Intelligence

RUDDOCK, LTD. (Photographers, Newcastle-on-Tyne).—£1,000 debentures, created April 26 and dated April 27, 1905, charged on the company's undertaking and property, present and future, including uncalled capital, have been registered.

ALLEGED PHOTOGRAPHIC FRAUDS.—On Saturday last, at West Bromwich, Albert Evans, alias J. R. Wilson, of no fixed abode, was charged with obtaining various sums of money by means of fraud in September last. It was alleged that prisoner called upon a number of poor people and represented that he was in the employ of the Midland Art Photographic Company, High Street, West Bromwich. He solicited orders and obtained deposits, but when inquiries were made at the Art Company his statements were found to be false. When arrested at Bilston he refused to give an account of himself. Prisoner was remanded in custody.

RE WALTER ELLIOTT LANDER, residing at 86, Belgrave Road, and carrying on business at 104, John Bright Street, Birmingham, photographic artist.—The first meeting of the creditors interested under this failure was held at the offices of the Official Receiver for the Birmingham district last week. The summary of accounts showed liabilities amounting to £165, and assets estimated to produce £27. Debtor alleged as the causes of his failure bad trade and want of capital. The unsecured liabilities include £153 2s. 10d. ordinary trade debts, and £12 12s. 6d. money borrowed. The case is a summary one, with the Official Receiver as trustee.

THE Official Receiver for the Windsor district has now issued particulars under the failure re Kathleen Ada Macdonald, photographer, of 57, High Street, Eton, from which it appears that the debtor has filed a statement of affairs showing gross liabilities amounting to £135, and a deficiency of £103. The report and observations of the Official Receiver upon the case are as follows:—The debtor, who has been adjudged bankrupt, states that her husband died on Sep-

tember 25, 1903, since which date she has carried on the business of a photographer at 57, High Street, Eton, formerly carried on by him. The unsecured liabilities have been incurred in respect of goods obtained and necessities supplied to the debtor and her family. As it is impossible to obtain a purchaser for the business as a going concern, agents have been instructed to dispose of the stock and furniture, either by private treaty or auction. The debtor states she became aware of her insolvency shortly after her husband's death.

News and Notes.

RECKLESS inaccuracy, we are sorry to find, characterises a paper on "The Chemistry of Photography" which the "Pharmaceutical Journal" prints in its issue of last week. The author, Mr. F. J. Young, should lay to heart Lord Salisbury's dictum: "Verify your references," before he again puts pen to paper. There is no excuse for a writer who so grossly misrepresents the early history of photography as to credit Talbot with the discovery of hypo as a fixing agent, and Scott Archer with the introduction of glass as a support for the sensitive film, and who derives the collotype process from Niépce's experiments with bitumen. It is a matter of regret to us that our contemporary should have set its seal upon a contribution abounding in misstatements.

ARTISTS have called Cropthorne, on the Worcestershire Avon, the prettiest village in England, and only a few years ago we would not have disputed its title to the distinction. Modern buildings have defaced somewhat its picturesque street, but, as readers of this month's "Studio" can see, there is at least one resident who is at pains to preserve the spirit of its mediæval beauty when elaborating his own home. A number of photographs show the delightful scheme upon which Mr. H. H. Avery has extended his house on the steep bank of the river, and has laid out an old-fashioned garden which would be the joy of photographers like Mr. Keighley. We are interested in the account because we have often made Cropthorne the scene of a holiday, and also because that for a large part of the restoration of the timbering the responsible person was Mr. Drinkwater Butt, F.R.P.S.

"ART IN PHOTOGRAPHY" is the title of a special summer number of "The Studio," which will be published about the end of June. The work of the leading photographers of the principal countries of Europe and America are to be represented, and in the selection of photographs which will appear, particular attention will be given to those which, in the opinion of the editor, possess special merits from the artistic point of view, and no particular school or style will receive more consideration than another. Essays on the British, French, Belgian, American, German, Austro-Hungarian, and Italian sections are being written by capable authorities, and the number should prove a noteworthy one for every photographer interested in the art side of photography.

PHOTOGRAPHIC GRANGERISING.—A writer in the "Bury Free Press," referring to the collecting of photographs recommended by Sir Martin Conway, and dealt with in a recent issue of the B.J., says: Perhaps the most perfect form of photographic collecting is that known as grangerising or extra illustrating, and this class of work can be made not only interesting to the collector, but even valuable to his district. The best thing to do is to decide upon some definite subject for illustration. If you are a competent botanist, geologist, or specialist in any other line, you may take a standard work on your own subject, but if you are merely an ordinary amateur, interested in the general life of the times, the best thing

you can do is to take the best popular history of your own town or village, or of your own county. Eventually the book will have to be taken to pieces and rebound (perhaps into several volumes), enriched with the photographic collections you have made to illustrate it. Meanwhile, it is simply used as a book of reference from which to make lists of desirable illustrations. You will naturally photograph all the places of importance mentioned in the book, which still preserve anything of their antique character. You will also copy old paintings, maps, plans, etc., illustrating the scenes or persons who made the history of the place, and will copy illustrations from other books which incidentally touch the subject. If you wish to continue the history up to date you may also take newspaper cuttings from modern magazines, etc., but this is going a little outside our special photographic interest. Strange as it may seem, there is a little text book entirely devoted to grangerising, and one which gives considerable attention to the photographic side of the work. It is written by a well-known photographic writer, H. Snowden Ward, and is published at the very modest price of 6d.

FASHIONABLE Photography in America.—Fashionable photography (says a writer in the New York "Tribune") has its fluctuations, its fads, its follies, and its fancies, little suspected by those who do not follow the subject closely enough to acquaint themselves with the varying phases that are constantly developed in this art. Some persons have an idea that simplicity in photography has come to stay; others that the most extreme elaboration in pose, colouring, and detail is the order of the day. The most artistic photographers are not bound by cut-and-dried rules, but strive continually to express a certain individuality in their pictures, a result which is accomplished in devious ways. The photograph which looks simplest when finished is often one that has cost hours of effort and consideration. The effect is everything. Now, how many persons are "effective"? A small proportion. It is the photographer's business, therefore, to make them so, and thereon hang all the secret ruses of his art. The photographer studies his subjects from every point of view, accentuates their good points by many interesting devices, eliminates their less favourable aspects by others equally so. Ladies often pose as long as two hours, during which time they have frequently been photographed in as many as twenty-five different attitudes. The sittings in fashionable studios have to be managed with no small amount of tact. Many persons consider the act of sitting for a photograph as private as what occurs in a doctor's consultation room. Many ladies suffer so greatly from nervousness that they refuse to have their husbands or other members of their families about while they are posing. But professional people, even those most famous, never care how large an audience they have in a photographic studio. They know they must be good-natured, or the tell-tale camera will reveal all. So the excessive temperamental phases that are experienced often with prima donnas are eliminated when a photograph is in question. The latest fad in posing is with tiny, thoroughbred dogs. Full-length pictures are more popular than ever, because they are better calculated to show off the creation of the modiste.

A **FIRM** in the Bristol district which is supplying a beautiful enlargement for nothing and then asking £6 6s. for the handsome frame (a very old version of the trick) was recently much annoyed because one of its customers who had supplied a print for a free enlargement met the partners of the firm when they came to deliver the goods, and on their stating that they required £6 6s., calmly produced a penknife, and, before they could effectively interfere, had cut through the backboard of the enlargement in such a way as to completely disfigure it. Of course, observes a writer in the "Bury Free Press," this action was quite illegal, but no doubt the grieved gentleman felt that he would rather like his free portrait acquaintances to bring legal action.

Correspondence.

PLATINUM PRINTERS' CATARRH.

To the Editors.

Gentlemen,—May I trespass on your valuable space in the hope of getting a little advice or information? I have been a printer for some twenty-two years, for twenty of which at least I have worked platinotype, as well as carbon, silver, etc. But for the last two years I have been troubled with a most distressing form of catarrh, with violent sneezing, running from the nose, etc. For a long time I treated this as for an ordinary cold in the head but without the slightest effect. Sometimes I am free for a week, but rarely longer, except when away from business. I have only lately been informed by a fellow-assistant that it is caused by the smell of the platinotype paper itself. My informant (a lady) assured me that she knew of a case of a lady printer who had to give up platinum work entirely owing to this troublesome complaint.

I had myself noticed that the most violent fits of sneezing, etc., came on when handling platinum paper, but I never dreamed of that being the cause in any way. That it is so I feel now quite convinced. I might say that the room in which I have to cut up and fill in is small and ill-ventilated.

Can you, gentlemen, or any of your readers, refer to a similar case, or suggest a remedy or relief? If so I should be extremely grateful, as it must be obvious to all how dangerous to good work such an unpleasant affliction is.—I remain, Gentlemen, yours faithfully,

OLD PRINTER.

[We cannot recall any similar case having been previously recorded. We should doubt the statement as to the trouble being caused by the "smell" of the platinotype paper, and should be inclined to ascribe it rather to mechanical irritation of the mucous membrane of the nose by minute traces of the sensitising salts being inhaled in the form of dust. Ferric oxalate being one of the salts used, we should lay the principal blame on this substance. The oxalates seem to be particularly prone to cause irritation, as the flower pickers of the Scilly Isles have lately been suffering from a peculiar skin irritation of the hands and forearms; and the Board of Agriculture, when appealed to on the subject, ascribed the effects to the raphides of calcium oxalate in the stems of the flowers. Assuming our surmise to be correct, the obvious remedy would be local application of emollients, such as hazeline lanoline, and the wearing of a chemical respirator covering the nose and mouth, which can be obtained from all chemical apparatus dealers. This can be filled with cotton wool, which could be soaked in weak glycerine and carbonate of soda—the air would thus be filtered before reaching the nose or throat. But probably ordinary care as to dust would obviate such drastic measures. We shall be glad to hear from any of our readers who may have met with a similar trouble.—Eds., B.J.P.]

AN EDITORIAL MILLENNIUM.

To the Editors.

Gentlemen,—The suggestion of Mr. John Tennant quoted in last week's "Ex Cathedra," under the title of "An Editorial Millennium," is a good one, and should afford your readers an opportunity and excuse for sending you numerous suggestions and small practical hints on photographic processes they can recommend as having

stood the test of practical work, and which they otherwise would not care to make the subject of a special communication.

The B.J. so admirably fills its appointed place in the photographic world, and caters so well for practically every class of serious photographer, that I cannot suggest any change, except that it might be published twice a week, and the price reduced to 1d.

A small practical tip occurs to me as I write, which may prove useful to other of your readers, as I do not recollect having seen it published anywhere. It is briefly as follows, and any one having a lot of enlarging to do with incandescent gaslight will appreciate it: Never use the whole of the ordinary mantle if it is desired to make the most of the light. It is well known that the smaller the source of light, provided it is sufficiently intense, when using a condenser, the better or more even the illumination of the negative will be.

When the usual mantle is made incandescent quite a large area of light is presented to the condenser, and I have found that the illumination is not so brilliant as could be obtained if the same amount of light was concentrated in a smaller area. It will also be seen that a considerable portion of the surface of the mantle does not get incandescent, and the pressure or quantity of gas used does not seem to alter it; in fact, the best light is usually obtained when the gas is not turned full on. The plan I have adopted is to cut off nearly one-half of the bottom portion of the mantle before lighting it for the first time, and reducing the height of the crutch in proportion. By this means the whole of what remains is rendered intensely incandescent with the same pressure and amount of gas, and, I find, gives a more even illumination, as the same amount of light appears to be concentrated into a smaller area.

I do not know if this method is new, but I have employed it for enlarging for some time, and also in an optical lantern with every success, and can therefore recommend it to others.—Yours faithfully,
SYDNEY ELLINGTON.

Fairbrother Road, Northsea, May 22.

THE "Bromide Monthly" for May includes among its notable articles a continuation of a cash offer of 10s. 6d. per negative for subjects of certain classes suitable for postcards. The Rotary Photographic Company, Ltd., will send a specimen copy of our mail but always interesting contemporary for 2d.

In a series of competitions arranged by the "British Advertiser," half a guinea is awarded for the best photograph of a smartly dressed shop window. The "British Advertiser," as the article on another page indicates, is undertaking a commendable task in emphasising the importance of photography in modern advertising, and possibly many of our readers will be glad to see a copy of our contemporary, to which end they need only apply to Baldwin Street, Bristol.

THE R.P.S. Exhibition.—The date of the next exhibition of the Royal Photographic Society, at the New Gallery, 121, Regent Street, will be from September 21 to October 28. It has been resolved that no changes for wall space be made to the exhibitors in the Pictorial and the Technical Sections.

In the eighteenth annual report of the Battersea Public Libraries it appears that considerable additions have been made to the local collection in the reference library, including books, engravings, maps, and pictorial postcards with views of Battersea and the neighbourhood. The Library Committee will be glad to receive accessions to this collection, and they invite further donations, especially from amateur photographers and those who possess original drawings of buildings or views in the borough.

A MAMMOTH Photograph.—A photographer of Chicago (U.S.A.) claims to have taken the largest photograph in existence. It is a full-length portrait of Dr. Dowie, and measures 8 ft. by 4 ft. This portrait is not an enlargement, but from a direct original negative.

Answers to Correspondents.

^{} All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C. Inattention to this ensures delay.

^{} Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

^{} Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington Street, Strand, London, W.C.

^{} For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

W. Scott, Church Bank, Bradford. Photograph of Yorkshire County Cricket Team, Season 1905.

Crampton & Fitch, 15, Quarry Hill Road, Tonbridge, Kent. Photograph of the Australian Cricketers and Friends. Photograph of a Curiosity in Natural History.

G. A. Dean, 14, High Street, Rugby. Photograph of a Curiosity in Natural History. Large Nest with Four Blackbirds' Eggs and Four Thrushes' Eggs; the Birds having been seen sitting on the Nest at the same time.

R. N. Heyworth, 38, Prescott Street, Rochdale. Photograph entitled "The Last Steam Tram to leave Rochdale, May 8, 1905."

T. V. Higgins, 257, Boulevard, Hull. Photograph of John H. Parkyn, A.R.C.O., Principal of New School of Art, Anlaby Road, Hull.

R. C. Garalde, 106, Anlaby Road, Hull. Photograph of a Group of Three Fishermen Presented with the Albert Medals by the King.—Harry Snitrik, Arthur Rea, Wm. Smith.

TELEPHOTO.—Which size of Dallmeyer's system III. moderate power, negative attachment can be adapted to a Busch rapid aplanat C shutter set? ("B.J. Almanac," 1905, p. 439.) 2. Would 5 in. focus negative suit 10 in. and less positive lenses? My combination gives foci of 6, 7, 8, 9, and 10 inches. 3. What would suit single lenses 12, 16, and 20 inches? The expense makes me wish to buy only one negative attachment at present; the most useful.—A. C. M.

1. If you drop a line to Messrs. Dallmeyer they will tell you which of their moderate power, III., attachments (which is the most suitable) can be fitted. But your lenses are not at all suited for telephoto positives, which should be of the fixed R.R. type, and with an aperture of $f/8$ at the least. It would appear from your query that you misunderstand the principles of telephotography. Why not study a simple manual, such as "Telephoto Work," by Deller (London: Dawbarn and Ward, 1s.)? 2. A negative of half the focal length of the positive is a good proportion for moderate-power work. 3. Negative attachments of 6, 8, and 10 inches focus; but these single lenses are not suitable.

CALOTYPE, ETC.—Can you please tell me of any works dealing with the different processes such as Calotype, Ferrotype, and Solar Printing?—P. HOFFMAN.

Heft 6, Band II., of Eder's "Handbuch der Photographie" deals with these processes for both negative and positive work. Price 3 marks, from W. Knapp, Halle a/S, Germany. Any of the old English text-books treat fully of these processes. You may pick up Hunt's "Manual of Photography" for a few pence, or doubtless you could get one by advertising for it.

ANXIOUS.—We have written sharply to the firm on the matter, and have refused to allow our columns to be further used by them until we are satisfied that business is promptly transacted. Your best course is to see if the police in your town can help you, or, failing them, to proceed through a solicitor.

SFERO.—Your query involves some knotty points of law. A five-mile radius in a large town would possibly, in a court of law, be ruled as "an undue restriction of trade"; in a small town it might not. However, you seem to have signed the agreement agreeing to its conditions, which appear somewhat broad. We should recommend you to consult a solicitor on the matter,

at the same time showing him the original document. He will advise you as to its legality, or otherwise, better than we can who have not seen it in its entirety.

COLLOTYPE, ETC.—1. Which is the best method of making colotype negatives? Would it be better to make a transparency from original negative and copy same, or to make a print and copy it? Is there any good book on this subject; if so, where should I get it? 2. Can you also inform me of the best method of enamelling P.O.P. postcards?—**COLLOTYPE.**

1. If you have the original negative, it is usual to use that, if it is of the correct size, simply taking the precaution, if it is not reversed, to reverse it. If it has to be reduced or enlarged, and you have convenience for making transparencies, then it is certainly better to make a transparency from the negative, and make your new negative from that. The best books on colotype are Schnauss', 5s., and Fithian's, 2s. 6d., both published by Liffe and Sons. 2. As usual for P.O.P.: squeegee to polished glass or ferrotype plate and strip off.

RIGHT TO USE PHOTOGRAPH.—I should be grateful if you would advise me on the following subject: I was requested to photograph a group, which was reproduced in the "Daily Mirror." I was in no way consulted about the matter, neither was my name inserted under the reproduction. The reporter, I understand, obtained one of the originals from one of the party of the group. What I would like to ask is: Is it legal for the paper in question to do this without my having any claim on them?—**IN DOUBT.**

If you were paid for taking the photograph you have no copyright in it. If you were not, and took it for your own purposes, the copyright is vested in you. But if you have not registered it you have no claim.

CARBON PICTURES—CONTE CRAYONS.—1. Would you be kind enough to tell me whether the process used for producing mezzotint portraits (as used by —, —, etc.) is a trade secret, and, if so, whether you know a firm that undertakes it? 2. Also, where is Conté crayon, recommended in the JOURNAL of May 5 by Mr. Barrett, to be obtained?—**G. L.**

1. The pictures in question are by the carbon process, made on a special tissue and transfer paper. Such firms as the Autotype Company, Illingworth and Co., etc., will make them for you. 2. The crayons may be had from Messrs. Reeves, Farringdon Avenue, London, E.C., or possibly from your artists' dealer.

CARBON PICTURES ON ALUMINIUM.—Can you inform me of the easiest method of coating aluminium for single carbon transfer? Please accept my thanks for the flashlight formula, it works admirably.—**EN AVANT.**

Carbon prints (single transfer) can be developed direct on the aluminium, but it is a good plan to coat it with a substratum of insoluble gelatine beforehand, as that avoids the risk of the picture peeling off afterwards. A good substratum for the purpose is the following:—Dissolve 1 oz. of Nelson's No. 1 gelatine in a pint of water, then add chrome alum, 20 gr., dissolved in 2 oz. warm water—stirring well the while.

ENLARGING ON CANVAS.—Would you oblige by supplementing the instructions given last week for enlarging on canvas by suggesting a method of using a bromide emulsion for a similar purpose, one that is as simple as possible and contains the smallest possible amount of gelatine? It is a film of any sort that I desire to dispense with as far as possible.—**ENLARGER.**

It is hardly possible to obtain less "film" with any emulsion formula than is given by the process suggested last week; but on page 288 of our issue for April 14 appears a formula under the title of "Home-Made Lantern Plates," which should

be satisfactory, if the additional gelatine which is there directed to be added after digesting the emulsion is omitted. This will give about 5 grains of gelatine to the ounce in the finished emulsion. It might be possible to reduce this still further, even to half the quantity, if some alcohol were used, say one ounce instead of an ounce of water in the bromised gelatine. The danger in reducing the quantity of gelatine too low is that a coarse granular bromide of silver is formed which has a tendency to settle down to the bottom of the vessel, and the emulsion gives then flat and foggy results; if these coarse grains are distributed through the emulsion, they are reduced by the developer in the shape of black spots.

J. W.—1. J. Avery and Co., 81, Great Portland Street, W., will supply you. 2. If the lens is in good condition you should advertise it, but we do not expect you will get very much—about £3 at most—as modern lenses have largely taken the place of this type. 3. Any light colour, preferably of a blue tint. A dado of a darker shade will assist the appearance of the studio, and not cut off any necessary reflected light.

E. D.—You can copyright the photograph used as the background, but you cannot copyright the style of portrait. Anyone has a right to produce similar effects, even from precisely the same view as you selected. The picture is good, but would be better without the vase.

COPYRIGHT.—A local professional photographer has taken the photograph of a group of workmen. He is charging 2s. per copy, whole-plate size. I wish to copy this photograph and put it on picture postcards for sale to the men, who can afford these better than the large photo. Am I infringing any copyright in doing this? Or is "the reasonable expectation of sale to sitters and their friends" by the professional sufficient protection to me? I myself am an amateur.—**F. F.**

Of course you have no right to copy the photograph. The copyright is either the photographer's or the party's by whom he was commissioned. You had better give up ideas of profiting by other people's work.

W. THOMPSON.—The iron bar will not interfere at all, and would certainly strengthen the building. As the studio is so wide, we suggest that, instead of three feet at the ends, you should have about four feet six inches opaque. It is quite unnecessary to continue the glass to within a foot from the floor. Two feet six inches, or three feet, will be quite low enough, and will save materials for curtains or blinds, and have other advantages.

SEPIA SATIN TONES.—Will you assist by giving me a formula with instructions for obtaining sepia tones on platinum papers?—**PLAT.**

Develop with a mixture of equal parts of:—(a) Potass oxalate, 2 oz.; water, 14 oz.; and (b) potass citrate, 150 grains; citric acid, 240 grains; mercuric chloride, 90 grains; water, 14 oz. (used slightly warm). The Platinotype Company make a special sepia paper. Why not employ it?

**** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

EX CATHEDRA

Ancient Lights. An important explanation was given by Mr. Justice Farwell last week of the present position of this question, which is too often a vexed one. In the well-known case of *Colls v. Home and Colonial Stores*, 1904, the House of Lords laid down the principle that interference with ancient lights in order to be actionable must amount to a nuisance, and there was a general impression that this decision had upset previous rulings, whereas what the *Colls* case had actually done was to readjust the law, and, whilst there was still a question of nuisance or no nuisance, the main point was not how much light had been taken, but how much was left, and whether that was enough for the comfortable use and enjoyment of the premises according to the ordinary requirements. The result is that the owner of property who complains of an obstruction to his ancient lights by the building operations of an adjoining owner should, before embarking in litigation, satisfy himself that he has suffered a substantial privation of light sufficient to render the occupation of the house uncomfortable, and to prevent his carrying on his accustomed business as beneficially as he had formerly done. This is a subject which may be of considerable importance to some of our professional readers.

Sunlight Dangers. In the last issue of the "Pharmaceutical Journal" is a letter calling attention to what is termed the curious origin of a fire that occurred in the writer's premises—a chemist's shop. It appears that one day recently, before the shop was opened, the rays of the morning sun passed through a show carboy of red-coloured water on to some dark slides which were wrapped up in a black focussing cloth. A passer-by, noticing smoke, gave the alarm, and the fire was put out before much damage was done. The writer says it would be interesting to know if anyone has had a similar experience? Accidents of this description, owing to the

sun's rays being focussed on combustibles, used to be by no means uncommon. At the time when graphoscopes were in vogue with their six-inch lenses, more than one case is on record of the woodwork being set alight by the sun's rays coming to the burning focus upon it. We know of a case in which an accident which might have ended in a serious fire was occasioned by a Woodward's solar camera with a twenty-inch condenser. The camera had been in use in the morning, and the mirror, driven by a heliostat, was turned round so that the sun's rays did not reach the condenser. Later in the day the rays were again reflected on the condenser, with the result that the woodwork of the camera was set on fire and a certain amount of damage was done to the room. Opticians, in arranging their windows, as a rule take care that reading-glasses and the like are so placed that this sort of accident does not arise. Curiously enough, the letter in our contemporary calling attention to the matter is headed "Inflammable Dark Slides," which would almost lead one to surmise they were not the ordinary wooden ones. A few at times, it is true, are constructed with celluloid shutters. Had that been the case in this instance there would have probably been more damage done than was the case. They may have been fitted with millboard shutters, but this can by no means be considered as being more inflammable than wood.

Death of Ludwig Schrank.

It is with great regret that we record the death at Vienna, on May 20, of Herr Ludwig Schrank, the editor of our contemporary "Photographische Korrespondenz." Our confrère had been before the continental photographic world for many years, both as editor of the "Korrespondenz" and as secretary of the Vienna Photographic Society, and at the time of his death he had attained the age of 77 years. An astute and strong man, the energies of his life were poured out freely in the interests of his journal, and under his care it has maintained its position at the head of the continental photographic press. Few photographic periodicals commanded the respect which the "Korrespondenz" obtained from us, and we add our regrets to those of photographers in the Austrian capital.

Local Views.

Although the local view as a source of income is nothing like what it was a few years ago, having been killed by the picture postcard, it is still often worth doing as a means of attracting attention to a business establishment. The local photographer has many opportunities denied to the operator of some large firm who goes to a locality for a week or two, and takes his negatives of the place pretty much as he finds it. Just at present, for instance, in many parts of England where the leaves are not more than half opened, views or

glimpses may be got through the trees, and the effect is less bare and wiry than when absolutely unclothed branches and twigs are spread across the sky. The last few weeks have also afforded excellent opportunities of securing views with natural skies on the landscape negative, and far-sighted workers will undoubtedly have accumulated or are still accumulating a number of cloud negatives by the aid of orthochromatic plates and a suitable light filter.

British Optics.

The Optical Convention, the report of which figures largely in our pages this week, is an eminently British institution. It is initiated and organised by Englishmen, and the large exhibition of optical apparatus to be seen this week at the Northampton Institute is the work of British firms. This exhibition is perhaps the most important part of the Convention. It demonstrates the importance of the optical trade, and shows that, though England has culpably divorced science from manufacture in optics, yet there are still qualities which make the English optician proud of his profession, and yet means for grafting the scientific method to the practice of the British optical instrument maker. In applying itself to this task, the Convention has the heartiest support of all who desire to see the British optical trade worthy of its great traditions. The report of the proceedings will be continued next week.

The Dublin Convention.

Elsewhere this week we publish full particulars of the arrangements made for the 20th Annual Convention at Dublin, and also names of the gentlemen composing the various committees. We would particularly draw the attention of our readers to the facilities that have been granted not only by the London and North-Western Railway Company, but also by the local Irish railway companies, for the convenience of conventioners taking part in the excursions. That full advantage will be taken of the cheap tickets, which will be specially issued, we have no doubt, and the opportunity of visiting the sister isle at the best time of the year, and at very little expense, should be made the most of by every photographer who is looking round for a place to visit for his summer holiday. To all such we advise a speedy application to the hon. sec. for terms of membership.

The Northern Photographic Exhibition.

Reports to hand from the secretary of the forthcoming Northern Photographic Exhibition at Leeds indicate that the show will probably be as large as, if not larger than, any previous photographic exhibition ever held in those parts. If careful organisation and enterprise on the part of the executive make for success there ought to be no doubt as to the result, both as regards public appreciation and financial returns of a highly satisfactory nature. As we have previously announced, the exhibition will be open from July 4 to August 12, and all exhibits must be delivered not later than Tuesday, June 20, at the City Art Gallery, Leeds. Entries close on Thursday, June 15, so all intending exhibitors who have not yet obtained entry forms and particulars should get them without delay from the hon. sec., Mr. F. G. Issott, 62, Compton Road, Harehills, Leeds.

The National Photographic Record Association.

The Annual Report of this useful and praiseworthy organisation is extremely satisfactory, not only in view of the work actually accomplished, but also on account of the increasing amount of vitality and interest evidenced. At the annual meeting held on Tuesday afternoon, at the Midland Grand Hotel, St. Pancras, the Hon.

Secretary, Mr. George Scammell stated that 374 prints had been received during the year for the British Museum collection, making a total of 3,504 prints received since the Association was founded. From their indefatigable president, Sir Benjamin Stone, a selection of a series of photographs taken in Scotland had been received. These included some of the National Sports, and ought to prove of great interest in the future. A selection of a series of places of interest on account of their association with the life and work of John Bunyan was also contributed, and a great number of others of varied subjects indicated the great interest Sir Benjamin took in all kinds of photographic record work. A large number of recently contributed photographs were on view at the meeting, and general satisfaction was expressed at the re-election of Sir Benjamin Stone as president for the ensuing year and Mr. Scammell as hon. secretary. It was also announced that three members of the Association have each offered to make fifty prints for the Museum collection from any suitable negatives. This offer should certainly be taken advantage of by every photographer who possesses negatives likely to be of interest, but who has no time to prepare suitable prints for the purpose. The hon. sec. will send full particulars on application to 21, Avenue Road, Highgate, London, N.

Local Record Work.

It is also exceedingly gratifying to learn from the report of the Association that during the year many efforts to extend the movement for photographic record work have been made by quite a number of photographic and scientific societies. Amongst others, the county of Surrey has now a strong society. The collection is permanently housed at the Public Library, Croydon, under the care of the Hon. Curator, Mr. J. S. Jast, and at the last exhibition of record work held in the Town Hall, Croydon, some 700 prints were exhibited. The photographic Survey of Essex are depositing their collection in the Essex Museum of Natural History (the Passmore Edwards' Museum), West Ham. In Kent, a County Photographic Record has also been founded. Their collection is being deposited in the County Museum at Maidstone, under the care of the Hon. Curator, Mr. J. H. Allchin. Since the last meeting, the National Photographic Record Association arranged an exhibition of record work for the Selbourne Society at their annual soirée at Burlington House, and have lent their lantern slides illustrative of record work to several photographic societies interested in the work. They have also been consulted by some of the colonial societies, including the Antiquarian Society of Montreal, who are organising a record society for Canada. In addition to this it will be seen from the account in another column that the Dundee and East of Scotland Photographic Society has practically accomplished a *magnum opus* in the shape of a photographic record of Dundee with suitable literary embellishments. The assistance granted by the town authorities—who eventually become owners of the volume—must, however, have been of immense assistance in this case, as so far we are aware no other town has yet undertaken the responsibility of handing down to posterity a complete and pictorial history of its people and their life in all its phases for the use of future generations.

Prints for the N.P.R.A.

A point in the annual report of the National Photographic Record Association should be borne in mind by everybody desiring to contribute, but who have not done so because it was imagined that only certain kinds of prints were admissible. There seems to be considerable doubt as to the size of print that will be accepted by the Council for the Museum col-

lection. They would like to make clear, therefore, that although whole-plate is considered the standard size, half-plate or even quarter plate prints are also acceptable, as many interesting and desirable records can well be, and often are, made on the smaller sized plates. This is particularly useful to remember in view of the appeal made by Mr. Malby at the annual meeting. He specially wished to draw the attention of all workers for the association to the recording of events of our every day life. Small events of present day industries, customs, manners, and even costume, that are not important enough for the illustrated press, would, if carefully portrayed by the camera, be of immense value to the historian in the future. This is quite in agreement with our suggestion made in last week's "Ex Cathedra," and we are pleased to see from Mr. Scammell's letter on the subject—published in another column, that a certain amount of this type of record work is being accomplished. But, as Mr. Malby pointed out, it should go further than endeavouring to record customs, etc., that are dying out. The golden opportunities to record present every-day customs in full vigour should also be taken advantage of, and in this we fully concur.

* * *

Sir Benjamin Stone and Photography.

The president of the National Photographic Record Association made his views on the practical application of photography very clear at the annual meeting on Tuesday last. He stated that the two points he would like to insist on were, first, that photography should find a prominent place in every school for educational purposes in the shape of lantern slides. The intelligence of every child could be more readily appealed to through the eye than the ear; and, secondly, that every photographer should apply his knowledge to the duplication of all national documents to which they could have access. It was deplorable to think of the priceless documents that had, even in recent years, been destroyed by fire or otherwise, and of which copy remained that could have the authenticity of a photographic replica. In support of this Sir Benjamin produced photographic copies he had made of certain valuable documents in the British Museum, which were usually kept hidden from the public gaze. They included the oldest written document relating to this country—a letter of King Arthur, and copies of Magna Charta, and other historic relics of the same nature were also shown. He contended that such photographic copies had a distinct educational value, as they showed the beginnings of our country's history in a manner nothing else was capable of, and said that in every town and in every city there were valuable documents and charters, etc., that ought to be duplicated by photography, and without delay. That this was not being done was owing to the fact that there was so much photographic waste—owing chiefly to photography having become such an easy process. A higher level of photography was wanted, and then its application to serious record work would be assured.

* * *

Mercury Ointment.

A paper in the "American Journal of Pharmacy" discusses the preparation of the mercuric ointment suggested in our issue of May 19, as affording relief from bichromate disease. The use of metallic mercury in compounding the ointment is considered inadvisable since it gives both mercuric and mercurous nitrates in the final product. As the method of preparing the most effective ointment may be of interest in carbon-printing establishments, we quote the formula and instructions:—

Red mercuric oxide	2½ oz.
Nitric acid	6 oz.
Lard oil	27 oz.

"Heat the lard oil in a clean glass or porcelain vessel to a temperature of 212 deg. Fahr., or the dish may be placed into a bath of hot water until the temperature of the oil has risen to about 212 deg. Fahr. Then withdraw the heat, gradually add 3½ oz. of nitric acid, and when the reaction moderates, re-apply the heat until effervescence ceases. Positively at this point in the process, the liquid should not be disturbed by stirring. Now when all the nitric acid has been decomposed, the temperature can be considerably raised without causing further effervescence, and the liquid simply boils. This elevated temperature may be maintained for ten or fifteen minutes, whereby the volatile fatty products will be more or less completely dissipated. Then allow the mixture to cool to about 104 deg. Fahr. Having dissolved the red mercuric oxide in the remainder of the nitric acid without heat, by adding the former to the latter in small portions, add this solution to the nearly cooled fatty product. Now raise the temperature of this mixture to 130 deg. Fahr., and maintain it at this until no further evolution of gas takes place, and then withdraw heat entirely. When the mass has become entirely cold, mix thoroughly by trituration, preferably by the use of a glass rod."

PHOTOGRAPHIC PRINTING PROCESSES.—IV.

SEMI-PLAIN PAPERS.

The following processes may be considered to stand practically between the plain papers already described and those in which an emulsion in collodion or gelatine is used; the image is entirely on the surface, and they have a semi-matt appearance. The resin and shellac papers are rather prone to yellowing of the whites unless used within a very short time of their preparation, and further they are not so suitable for gold as for platinum toning. The shellac paper is prepared as follows:—

White shellac (powdered)	96 grains
Distilled water	2 ounces
Liquid ammonia .880	50 minims

The shellac should be rubbed up with the water, the ammonia added, and the mixture heated till solution is effected. A little more ammonia is added if necessary, and the solution cooled and filtered. It will keep indefinitely.

The size is prepared by first making an arrowroot solution:—

Arrowroot	60 grains
Distilled water	2½ ounces
Ammonium chloride	54 grains

to which is added, whilst warm

Shellac solution	1 ounce
------------------	--------	---------

and after well stirring, the mixture is spread on the paper in precisely the same way as with the other sizes, allowing half an ounce for smooth papers and three quarters of an ounce for rough-surface drawing papers. The paper must be dried as quickly as possible.

The silver bath must be stronger than for plain paper, and it is advisable to use rather more water so that our formula for 480 square inches becomes

Silver nitrate	60 grains
Citric acid	40 grains
Distilled water	¾ ounce.

The ammonia nitrate must not be used, as this dissolves

out the shellac and gives a lumpy surface; but it is advisable to fume the paper before printing.

After printing the prints should be immersed in salt and water, and toned in the following bath, heated to 80 deg. Fahr.:—

Potassium chloroplatinite	2 grains
Phosphoric acid (dilute)	$\frac{1}{4}$ ounce
Water	2 ounces

The most economical way of using this bath is to place the print, face up, on a sheet of glass, remove the surface moisture and brush the bath over it; in about three minutes it will have acquired the necessary depth of tone.

The resin paper is a little troublesome and rather more care is required in the preparation of the size, as it is easy to obtain a lumpy mixture, which is useless.

Pale yellow resin	40 grains
Distilled water	2 ounces
Liquid ammonia .880	q. s.

The resin should be obtained in clear, clean lumps, not in powder form, as the latter gives a darker film. It is, however, finely powdered before use. Water should be heated to boiling point and some ammonia added, and then the resin added by degrees, with constant stirring and the heating and addition of ammonia continued till a clear solution is obtained. This is not a pleasant operation as the heat, of course, drives off the ammonia, and further, some little resin seems to refuse to dissolve. In any case the solution must be filtered.

The next procedure is to make a solution of gelatine, thus:—

Hard gelatine	40 grains
Distilled water	2 ounces

Allow to soak for half an hour and dissolve by the aid of heat, and if necessary filter, and to this, whilst still warm, should be added the resin solution with constant stirring, then should be added very slowly and with constant stirring:—

Ammonium chloride	96 grains
Distilled water	2 ounces

If now the solution smells of ammonia, pure hydrochloric acid should be added till it is neutral, and then enough saturated solution of citric acid until the reaction is

distinctly acid. This is not an easy matter, as the incautious addition of the acid instantly throws out the resin in lumps instead of in fine grains. The total bulk of the solution is finally made up to 10 fluid ounces.

The sensitising solution may be of the same strength as that recommended for the shellac paper, but the citric acid should be reduced to half the quantity. The remarks as to the use of ammonia-nitrate for fuming also apply here.

By using a preliminary gold-borax bath, washing, and then employing the above-mentioned platinum bath, warm black tones are readily obtained.

We now come to a process, suggested first by von Hübl, which is by no means difficult, and permits considerable variations in effect by ringing the changes on proportions of the various ingredients, particularly as regards the ratio of albumen to arrowroot. The more of the latter, the less the characteristics of the paper approach those of ordinary albumenised paper.

White of egg	1 oz.
Arrowroot solution, 2 per cent.	1 oz.
Salt	30 grains

This is the size, and it can be brushed over the paper as already described. The albumen must be, of course, whipped to a froth, allowed to stand for a day and the clear portion only used. It is mixed with the arrowroot solution only when the latter has cooled to about 90 deg. Fahr., coagulation being avoided by taking this precaution.

The silver solution for this process may be either neutral or acid, the former being suitable for gold toning, and the latter for platinum. If the acid sensitiser is used the formula should be:—

Silver nitrate	40 grains
Citric acid	5 grains
Distilled water	$\frac{1}{2}$ ounce

which can be applied as described on page 363, in our issue of May 12.

The paper should not be sensitised with ammonia-nitrate, and if for platinum toning, must not be fumed. In these latter formulæ variations in gradation may also be obtained by using phosphate or bichromate as previously described, and the principles set forth in the previous articles are generally applicable to these semi-plain papers.

THE WEEK IN HISTORY.

The First Platinotype Process.

NEXT Monday, June 5, exactly thirty-two years will have elapsed since the first patent for platinum printing was taken out. In 1873, Mr. William Willis, junior, filed with the Patent Office a description of "Improvements in Photo-mechanical Printing," the importance of which, perhaps, even he did not place at a sufficiently high value. Platinotype, as set forth in his specification, is a more complex process than that of to-day. A fixing bath of sodium hyposulphite, or ammonia, figures prominently in the specification, and its use was apparently considered an essential part of certain forms of the process. I believe it was necessary to use it so long as oxalic acid was employed as the final clearing bath, and at this stage of the process no mention is made of hydrochloric acid as the clearing agent or remover of the iron salts.

It is rarely that one sees a printer's error in a patent speci-

cation, but in this one "ferric oxalate" in one place is printed "fabric oxalate."

Commenting on this first platinotype process, THE BRITISH JOURNAL OF PHOTOGRAPHY wrote, "The specimens of this process which we have seen are exceedingly fine and possess the most delicate gradation with much vigour" — words which surely can bear further emphasis in reference to the modern results of platinum printing.

It was some years after its introduction before the platinotype process met with much favour amongst photographers, and it was introduced before its time, like some other processes. At that time glossy albumen paper, with its purple tones, had all the run, and the public then did not appreciate the beauties of matt surface pictures with the rich blacks that platinotype yields. The case is very different now with the more refined portion of the public.

HISTORICS.

THE OPTICAL CONVENTION.

The Optical Convention opened on Tuesday evening last, May 29, under the presidency of Dr. R. T. Glazebrook. The aims of the Convention are to increase the interest taken in optical science in this country, to promote an improvement in technical education in optical matters, and to aid the development of the British optical industry. In selecting the Northampton Institute as the seat of its operations the committee were fortunate in associating their work with that of the optical department of that institution, the director of which, Mr. S. D. Chalmers, M.A., has actively taken up the arrangement of an important programme of papers and discussions. Among others to whom the Convention is indebted for great help is its honorary

secretary, Mr. F. J. Selby, Dr. J. M. Walmsley, the Principal of the Northampton Institute, Mr. W. Rosenhain, and Mr. E. B. Knobel, who has acted as treasurer of the Convention funds. The movement has received the support of such leading scientific men as Lord Kelvin, Lord Rayleigh, the Earl of Rosse, Lord Blythswood, Professor Poynting, Professor Schuster, Professor Silvanus P. Thompson, Sir William Abney, Sir Howard Grubb, etc., etc. The Optical Society, the Spectacle Maker's Company, the British Optical Association, and the various optical associations in the provinces have given active help, and most of the leading makers of optical instruments are taking part in the Convention.

THE PRESIDENTIAL ADDRESS.

Dr. R. T. Glazebrook, in the course of his address on Tuesday last, after explaining the origin of the proposal to hold a Convention, and the steps taken to realise it, gave an outline of the history of optical progress during the past two hundred and fifty years, with a view of illustrating the close union which has existed between theory and practice at times of marked progress, and of showing how each has reacted on the other in assisting this progress.

The growth of the science at the end of the seventeenth century was due to two men, Christian Huyghens and Isaac Newton. Each appears to have been directed to theoretical optics from a desire to improve the telescope for astronomical purposes. Each was in his own way a mechanic: Huyghens built telescopes and clocks; Newton, at the beginning of his optical work, applied himself to the grinding of optical glasses to figures other than spherical. Huyghens and Newton were the authors of the two rival theories of optics which held the field for not more than one hundred years to the days of Young and Fresnel. That period was not very fruitful, either in theory or practice, but Fresnel by his work established Huyghens' theory, and though

he did not directly add much to practical optics, he entirely changed the position from which the theory of optical instruments has to be regarded. Recent progress in the theory of the telescope, the microscope, and the spectroscope is based on his work.

In the address the work of the two Herschels and Airy at the early part of the last century was alluded to, and the important part in the development of English optics taken by Messrs. Chance through their introduction of optical glass was described. It was pointed out, however, that by the middle of the century there was a marked separation between the theoretical and practical workers, so that when photography was invented by Daguerre, Airy's work on the aberrations of a lens and Hamilton's important theorems on rays were unknown to the lens designers. Thus for many years the photographic lens developed empirically.

Some account of the change in the position due to the work of Ernst Abbe, and the development of this work at Jena and elsewhere, brought the address to a close.

THE SPECIFICATION AND MEASUREMENT OF OPTICAL ABERRATIONS.

(A Paper read before The Optical Convention on Wednesday, May 31.)

Among the subjects which it is desirable to have discussed before this Congress with a view to arriving at some consensus of opinion, perhaps none are so important as the defining of the meaning of the various optical aberrations, and the standardising of methods of testing and comparing the performance of different instruments.

The importance of this discussion is threefold. In the first place, it may be of important assistance to the designers and manufacturers of optical instruments, who at present are somewhat at variance on some of the criteria leading to design. In the next place, the possibility of having the various aberrations numerically stated would enable the users of such instruments to select them with reference to their special requirements. It is a well-known fact that in the higher class of optical instruments, extreme perfection of one or more attributes of the instrument is frequently attained by the sacrifice of perfection in others; and in the absence of exact information, an individual frequently obtains an instrument which, though of the greatest excellence in several respects, may be deficient in the most important feature for which he requires it. As instances may be quoted, the employment of microscope objectives of very high N.A. for work where depth of focus is required, and the use of photographic lenses working to apertures of $f/4$ for process work, in which the zonal spherical aberration when used for apertures of $f/22$, as is common in process work, may be larger than with a cheap lens of small aperture. Lastly, and most important, the adoption of some definite tests and the certification of optical instruments would deal the death-blow to the worst feature of the optical industry, namely, the continued misrepresentation, both unintentional and otherwise, as to the quality of the various instruments. It is an open secret that at the present time there are no official tests or certificates which will discriminate between the performance of the better types of instruments; and while this remains the case, it is obviously impossible to expect manufacturers to refrain from claiming the greatest perfection, or that much encouragement will be given to the attainment of it. The adoption of a satisfactory method of defining and measuring the aberrations of optical instruments will be the most important step towards raising the status of the optical industry in the country.

In dealing with the general principles of aberrations in optical instruments, it must not be forgotten at the outset that optical image-forming instruments fall naturally into two distinct classes—objective and subjective. To the former class belong all instruments in which an image is formed upon a screen, such as photographic lenses, projection apparatus, etc., while the latter includes instruments such as the telescope and microscope, in which the image is virtual, and is only visible to a single observer. In the former case the instrument is complete in itself, and its only function is to produce a perfect image upon the screen, but in subjective instru-

ments the final object is to produce a perfect image upon the retina of the observer, and this depends upon the visual apparatus as well as upon the instrument. Instruments for subjective use, therefore, should have their aberrations defined with respect to the normal eye, and the tests made on them should either be visual in character, or preferably objective and corrected for the errors of the normal eye.

Next, aberrations should be specified absolutely and relatively, the former with the object of stating the actual performance of an instrument, the second in order that the comparative merits of various forms can be arrived at. The basis of this comparison needs settling.

Lastly, aberrations may be classified into primary, secondary, tertiary, etc., depending upon the degree of approximation. This distinction is mainly of importance to the designer and manufacturer.

It is evident that a great many complex questions are involved, and it is hoped that discussion following this paper will settle them.

We have therefore made the following classification of aberrations into—

A. Objective or Subjective.

B. Absolute and Relative.

C. Primary, Secondary, or higher.

and it is proposed to very briefly discuss this classification.

Aberrations of Objective Systems.

At the outset it seems necessary to come to some decision as to the definition of an aberration. Aberrations have been specified as the distance between the foci of two sets of rays or longitudinal aberrations. This is notably the case with radial astigmatism, where the distance between the primary and secondary focal lines is usually taken as a measure of the defect. In other cases, the diameter of the circle or patch of least confusion is regarded as the criterion. Neither of these are perhaps the most suitable method of expression. The ultimate object of an optical system is to give an image of as perfect a character as possible on a surface that is usually a plane. What we are therefore concerned with is simply the lateral departure of the edges of a pencil from the point in a plane to which they should be brought in a perfect optical system.

It only remains to select the plane and define the perfect optical system. Now the simple approximate formula of Gauss would, if true for large apertures and angles of view, satisfy the conditions for perfectly sharp images in collinear relationship, and would at the same time specify the image plane. We may therefore define the perfect optical system as one in which all the light emerging from one point of the object plane is focussed to a single point on the corresponding Gauss image plane and in the exact position given by the Gauss formulae. Any departure of the light from this position constitutes what should be termed the lateral aberration or absolute

aberration of the pencil, while this lateral departure divided by the distance of the image plane from the principal plane of emergence may be termed the angular aberration of the pencil. These definitions are consistent with the all-important mathematical theory of Von Seidel, and may be said to be the fundamental assumptions upon which the whole of his work is based.

The primary aberration, or aberrations of the first order are of seven well-known kinds:—

- (a) Chromatic aberration of the image plane.
- (b) Chromatic aberration of the magnification.
- (c) Central spherical aberration.
- (d) Coma.
- (e) Radial astigmatism.
- (f) Curvature of the field.
- (g) Distortion.

Definitions of the Various Aberrations.

If the general definition of an aberration above stated be accepted, little need be said about the separate errors.

Central Chromatic Aberration.

In this case there can be little doubt that, so far as instruments intended for visual observation are concerned, whether objective or subjective, the standard plane should be that for the D line, and the chromatic aberration of the image plane should then be the diameter of the disc formed on the axis at full aperture for either the C or F line, whichever is larger. For photographic instruments the standard plane might still be for the D line, and the size of the disc for the F or G line might then express the chromatic error.

Chromatic Differences of Magnification.

Here the amount of the error would similarly be the distance of the focus of a narrow pencil passing through the centre of the diaphragm for the C, F, or G light respectively from that for the D light on the plane at some specified angle of view. This angle would probably be the extreme nominal covering power of the system when this is known.

Other Aberrations.

Spherical aberration would be on this basis the diameter of the disc produced at full aperture on the axis on a plan focussed for a narrow central pencil using sodium light.

Coma might be defined as the difference between the distances of the top and bottom edges of the patch formed by an oblique pencil at the specified angle, and at full aperture from the position on the plane to which the centre of the incident pencil is refracted.

Radial astigmatism would similarly be expressed by the difference between the diameters of the elliptic patch formed on the standard plane at full aperture and at standard obliquity, or their sum if the primary and secondary foci lie on opposite sides of the standard plane.

Curvature of the field might be measured by the mean diameter of the patch, or the half difference of the diameters when the focal lines fall on opposite sides of the screen at full aperture and standard obliquity.

Distortion on the basis of these considerations would be measured by the displacement of the image for a narrow pencil at the standard obliquity intersecting the axis at the centre of the diaphragm, from the position given by the Gauss relations. If x_2 is the lateral distance of the image from the axis, x_1 that of the object, then $x_2 - mx_1$ will be the distortion, m being the Gauss magnification $\frac{v}{u}$.

Subjective Aberrations.

In dealing with aberrations from the subjective point of view it is necessary to first decide upon an important point. We may either consider the eye as fixed, in which case the function of the instrument is to produce a perfect image over the whole of the retina; or as rotating, which implies that both central and oblique pencils from the optical system should be of the same character, such as to be focussed sharply upon the macula when the optic axis is coincident with the axis of the pencil. Of these two it would appear that the second is the more rational, as when the eye is fixed, all but the one point is seen by indirect vision; in which case small errors of definition are not of consequence, while, if an object is intentionally viewed obliquely, the axis of the eye is rotated into that direction. We may therefore take the view that for an optical instrument to be perfect for subjective use, both oblique and central pencils should be of exactly the same character, and have equal and opposite chromatic and spherical errors to those of the normal eye.

So far as the writer is aware, no determinations of the amounts of the spherical and chromatic defects of the eye have been published, and it seems advisable that investigation should be made on these points as, if definite figures were available, designers could use them in their calculations. No great difficulty should be experienced in determining the amount of chromatic aberration. The writer has found it convenient to employ a pair of small

apertures which can be placed in front of the eye and separated until a distant point of light can only just be seen through both. When this is the case the two apertures are at the extreme edges of the pupil, and the point of light appears coloured. By interposing a prism of suitable angle in the course of the light to one of the apertures the colouration may be compensated. The writer has used the Risley rotating double prisms for this purpose, and from rough measurements on his own eyes is inclined to think the amount of chromatic aberration in the eye between the C and F lines amounts to about .7 dioptré, or approximately the same as for an uncorrected lens of the same focal length as that of the eye, as would be expected.

The determination of the spherical aberration appears to be much more difficult owing to its small amount. Perhaps the most convenient method would be to use a microscope with a small source of monochromatic light and a correction collar objective, or any other instrument into which a variable amount of spherical aberration can be introduced. By adjusting the objective until the spherical aberration was apparently perfectly eliminated according to the eye, and objectively testing the microscope so adjusted, the amount of the error might be found. It appears essential that any tests of the errors should be made on normal living eyes.

Measurement of Objective Aberrations.

There are three principal methods by which the amount of the aberrations of an objective system may be measured. First, we may actually examine the image formed in the Gauss image plane by a microscope or eye-piece in the manner employed by Mr. Conrad Beck in his apparatus for testing photographic lenses, and directly measure the dimensions of the patch of light so formed. In the second place, we may actually find the foci for different colours and for various portions, zones, or meridians of the system, and thereby deduce the amount of the various defects. This method has been followed by most of those who have worked at this subject up to the present, and forms the basis of the tests made at Kew and by Moessard with his tourniquet. Thirdly, we may deduce the amounts of the aberrations from observations taken considerably inside and outside the focus, the beam of light passing through the system being preferably split up into a number of narrow pencils by means of a perforated disc interposed before the system. This is the basis of the Hartmann test.

The writer's experience does not allow him to speak with any degree of certainty as to the relative merits of these various methods of procedure. Were it not for diffraction troubles, the preference should lie with the first method, as a high degree of magnification of the disc could be obtained and the amount of the defects directly determined with the aid of a perforated diaphragm, as in the Hartmann test. The use of such a diaphragm might also do much to eliminate diffraction troubles, as the centre of the diffraction system formed by a narrow partial pencil would indicate the true axis of that pencil. Should this not be practicable, the Hartmann test is to be preferred to the second method, as diffraction troubles are always greatest at the focus. The Hartmann test is practically unaffected by diffraction, and it has the further advantage of requiring fewer observations on the system itself, although the after measurement may be somewhat lengthy. If this method could be used equally well visually instead of photographically, it would be an advantage, and there seems no great difficulty about this.

Before dismissing the subject of the measurement of objective aberrations the writer would like to call attention to the advantage of employing reflection of auto-collimation as an aid to the other tests. If by means of a plane or spherical mirror the light is made to traverse the system twice by approximately the same path, its aberrations may be doubled in magnitude and thereby be more easily estimated. If the optical system is mounted axially, and the mirror is normal to the axis, the central chromatic and spherical aberration will each be doubled. Coma will be eliminated owing to the symmetry of the equivalent optical system about the mirror. By using a microscope or telescope with a plane unsilvered mirror in its interior, both as the luminous origin and the testing arrangement, great convenience and accuracy can be secured.

It will not be necessary to deal with the measurement of the aberrations of subjective instruments separately, as such instruments should be tested in the same way as objective instruments, and the correction for the normal eye applied to the results. The only essential difference in treatment is due to the fact that in subjective instruments the emergent beam is approximately parallel, and cannot therefore be directly focussed on a screen. By the employment of an auxiliary convergent lens of low power, or of which the aberrations are already known, the aberrations of the instrument should be readily terminable.

Relative or Comparative Aberrations.

Coming now to the expression of the results in a comparative form, the mathematical investigation of the aberrations of the first order leads to the following:—

The angular central chromatic aberration (the size of the chromatic disc on the standard plane divided by the second conjugate distance)

proportional to the relative aperture of the system (effective aperture divided by equivalent focal length).

The angular oblique chromatic aberration (distance between the images for lights of standard colours divided by the second conjugate distance) is proportional to the angle of obliquity.

The angular spherical aberration (of the first order) is proportional to the cube of the relative aperture.

The angular coma is proportional to the square of the relative aperture, and to the obliquity.

The angular astigmatism is proportional to the relative aperture to the square of the obliquity.

The angular size of the disc produced by curvature of the field is proportional to the relative aperture and the square of the obliquity.

The angular distortion is proportional to the cube of the obliquity.

As in the mathematical investigations of these aberrations, angles and their tangents are convertible, and the tangent of the angle of obliquity is immediately obtainable by dividing the lateral distance of the image from the axis by the emergent conjugate distance, it would appear most convenient to adopt the following definitions:—

Relative Central Chromatic Aberration.

This would be the angular central chromatic aberration, divided by the relative aperture. Or in symbols, $C_c = \frac{\Delta \omega}{v} \frac{f}{d}$ where $\Delta \omega$ is

the diameter of the chromatic disc, v the emergent conjugate distance, the equivalent focal length, and d the effective aperture of the stop. For microscopic objectives the numerical aperture would be substituted for $\frac{f}{d}$.

Relative Oblique Chromatic Aberration.

Following the above lines, this would be obtained by dividing the angular oblique chromatic aberration by the tangent of the angle of obliquity. This is obviously, however, the same as $\frac{\Delta \omega}{m}$ or $\frac{\Delta x}{w}$ where x is the lateral distance of the point from the axis, and Δx chromatic displacement.

Relative Spherical Aberration.

This will simply be the angular spherical aberration divided by the cube of the relative or numerical aperture, or $\frac{\Delta \sigma}{v} \frac{f^3}{u^3}$.

Relative Coma.

In the same way the relative coma will be expressed by dividing the angular coma by the square of the relative or numerical aperture, and by the tangent of the angle of obliquity or $\frac{\Delta \sigma}{x} \frac{f^2}{u^2}$.

Relative Radial Astigmatism.

This will be the angular astigmatism divided by the relative or numerical aperture and the square of the tangent of the angle of obliquity, or $\frac{v \Delta \sigma}{x^2} \frac{f}{d}$.

Relative Curvature.

From the definitions above given we have relative curvature as the angular curvature divided by the relative or numerical aperture and the square of the tangent of the angle of obliquity as with astigmatism, or $\frac{v \Delta \sigma}{x^2} \frac{f}{d}$. But on working out we find that this

expression becomes $\frac{f}{2r}$ where r is the radius of curvature of the field containing the circles of least confusion. The relative curvature therefore on this basis simply depends upon the ratio of the absolute radius of curvature to the equivalent focal length as would be the natural way of expressing it.

Relative Distortion.

Finally, relative distortion will be expressed by dividing the angular distortion by the cube of the angle of obliquity, or $\frac{\Delta \omega}{v} \frac{v^2}{w^3}$, which

may be written $\frac{\Delta x}{x} \frac{v^2}{u^2}$ or $\frac{\Delta m}{m} \frac{v^2}{x^2}$ or $\frac{\Delta x}{w \tan^2 \theta}$.

In the above we might have taken the angle of obliquity in degrees, but it would obviously have given us extremely small values for the relative errors.

Aberrations of Higher Orders.

It is not proposed to deal here to any extent with the subject of the higher aberrations, as they are so numerous and their relations are so complicated. A few words will, however, be devoted to one or two of them, in so far as they affect any of the conclusions above stated.

Dealing first with chromatic aberration, the definitions above given would not require modification for secondary or tertiary spectra. Chromatic differences of spherical aberration could be dealt with by stating the amounts of spherical aberration for two or more monochromatic lights.

Spherical aberration requires more consideration. The higher orders of this defect, or even the "spherical aberration" of the first order for figured lenses, will not depend on the cube of the relative aperture as above stated. In fact, the spherical aberration may be absolutely corrected for full aperture or any particular zone, and be of fairly considerable amount at lower aperture. Should this be found in testing, the best course would probably be to state the values on precisely the same basis as before for two or more values of the aperture.

The oblique errors of higher orders might perhaps be similarly expressed for one or two different apertures, and for, say, two values of the obliquity, the full covering power and half that angle.

It appears to the writer, however, that such great advantages would accrue from merely settling the tests and expressions for the elementary aberrations, that it would be better for the higher aberrations to be left on one side for the present.

In concluding this purely suggestive paper, the writer would call attention to the proposition made by Mr. Ryland at one of the recent meetings of the Optical Society, that a scale of marks should be adopted for optical instruments similar to that applied to watches at the Kew Observatory. Of course, much will have to be done in the direction of making a satisfactory scheme of tests before this would be possible, but in view of the impetus given to accurate watch-making by the Kew certification, the proposition seems worthy of being kept in sight, and acted on as soon as it may be found practicable. The summary of the properties of the lens might perhaps be on a schedule stating the equivalent focal length of the system, the positions of its principal or nodal points, and its magnification if a subjective instrument. There should also be stated the maximum numerical or relative aperture, the maximum illumination for visual or actinic light, the maximum field of view, and the uniformity of the illumination, with marks for each, while marks should also be given for the perfection of the mounting, freedom from flare-spot, parallelism of axes in binocular instruments, etc. Finally, dealing with the aberrations, a form of the following kind might be adopted:—

NATURE OF DEFECT.	ABERRATION.		MARKS.	
	Absolute. mm.	Relative.	Maximum.	Awarded
Central chromatic aberration at full aperture.....				
Oblique chromatic aberration at specified field.....				
Central spherical aberration at full aperture.....				
Coma, at full aperture and specified field.....				
Radial astigmatism at full aperture and specified field.....				
Curvature of field at full aperture and specified field.....				
Distortion at specified field.....				

The writer regrets that time has not permitted his consulting any authorities on this important subject, and is conscious that many of the suggestions and statements made above are open to criticism. He hopes, however, that they may form the basis of a useful discussion.

C. V. DRYSDALE, D.Sc.

ABERRATIONS.

(A paper read before the Optical Convention on Wednesday, May 31.)

Progress in the design of optical systems is dependent to a very large extent on the exact specification of the aberrations of the system, whether these aberrations be obtained from the theoretical calculation or the actual performance of the system.

It is of the utmost importance that the numerical specifications in these two cases should be directly and strictly comparable, and the methods employed should be of sufficient generality to permit of a

thorough test of the system. In addition it is desirable that these results should be capable of expression in a form which gives a definite numerical value to the definition at any point: the numerical measure of the aberrations should be sufficiently definite and detailed to allow the excellence of definition to be determined from the calculation of the aberrations only.

The only method of calculation universally applicable is the tri-

gonometrical method; this permits the ready calculation of the path of any ray through the system, though the calculation of rays not in one plane involves considerable labour. The results enable us to express the points in which the ray intersects the focal plane and any plane parallel to it. In this way the positions of the intersections of various rays proceeding from the same object point may

It will be noticed that the calculations also give directly the definition at any plane parallel to the focal plane. Various rays have been calculated through the lens $R_1 = +100$, $d_2 = 6$, $R_2 = -100$, $n_2 = 1.5168$, the object being taken on the axis. The rays through three points on the lens are considered, on the axis, at a distance of 10 mm. from the axis, and at a distance of 5 mm.

Fig. 1.

Fig. 3.

Fig. 5.

Fig. 2.

Fig. 4.

be determined, and one of these rays being taken as chief ray, will give the distortion expressed as a lateral aberration; while the definition at this point is indicated by the lateral aberration of the other rays relative to the chief ray.¹

¹ Formulae for this purpose are given, Steinheil u. Voit, *Angewandte Optik*; and Everett, *Proceedings Physical Society*.

The intersections of these rays with the focal plane are drawn out on a scale of 50 : 1. Fig. 1 represents the intersections of a ray with the focal plane. If any other plane be chosen as focus, the intersections can be immediately expressed. It is, however, convenient to indicate in this diagram the aperture to which the intersection corresponds.

The aperture of the lens is drawn out on any convenient scale, and the lateral aberration of each ray relative to the chief ray is measured from the corresponding point on the aperture diagram (Fig. 1). In this figure the aperture diagram is indicated by ●, and the actual rays by +, thus the distance between ● and the + represents the lateral aberrations on the scale shown.

Measurement of Aberrations.

Our standard method of testing the actual system should give the same information as the trigonometrical method of calculation. It should be absolutely universal and exact, and allow a subsequent choice of the best focal plane (which may be other than the theoretical Gauss plane or the plane which gives the best central definition). The method devised by Professor Hartmann² gives this information (although it has not yet been applied to microscopic objectives) for as many rays as may be desired.

Various beams of light, proceeding from a small circular source are isolated by means of a diaphragm with a number of small circular apertures (Fig. 2); these beams converge to form on the focal plane the image of the source of light, but may be intercepted on two planes at equal distances inside and outside the focal plane. If these distances are suitably chosen, the centre of the section of each beam can be determined, and thus the direction and position of the ray from the centre of each aperture is obtained; thus we have the point of intersection on the focal plane and on any parallel plane. The sections of the beam are most frequently obtained by exposing a photographic plate at the desired positions, and the final values of the lateral aberrations are obtained exactly in the same form as by trigonometrical calculation.

The method is susceptible of very great accuracy, and can be used to test how accurately the design has been carried out, the same rays being tested as were originally calculated. In addition, other rays can be tested, thus avoiding much of the labour involved in calculating the oblique rays of a system, especially those not in one plane. It is specially applicable to telescopic and photographic, including spectroscopic, apparatus.

The methods of measurement are, however, in their original form, much too laborious except for large astronomical refractors, and I have in practice found considerable simplification possible when dealing with photographic lenses. To make the results readily expressible in terms of the usual aberration specifications, the diaphragm is placed at the plane of the stop. The principle of obtaining the lens about the back nodal point enables the lens to be tested at various angles, a fixed collimator or distant source of light being used; a series of photographs inside focus can be taken on one plate and a corresponding series on another provided the lens can be set at definite angles. For this purpose the Beck lens-testing bench is used, a special fitting being attached to permit of the plate swinging with the lens holder, thus allowing all exposures being made on plates which are kept parallel to the focal plane. The photographs are examined microscopically, and a camera lucida used to draw a diagram showing the centre of each of the spots; when the first diagram is complete the other photograph is placed in the stage of the microscope, being reversed to bring corresponding spots in corresponding positions and compared with the other.

Where the visual best focus corresponds exactly with the best photographic focus, the two diagrams should be as nearly as possible coincident; but the magnification can be altered (within small limits) till the two central diagrams are as nearly as possible coincident; the whole series of diagrams are then drawn off, care being taken to bring each central spot into exact coincidence with the corresponding spot of the other diagram.

The distance between the two corresponding spots will then represent the lateral aberrations of the ray, on the scale of $m_1 + m_2$; 1 where m_1 and m_2 are the two camera lucida magnifications.

To permit of the focus being modified subsequently, it is desirable to redraw the second diagram with a different magnification m_3 . This corresponds to a change in the position of the focus.

$$= \text{distances between exposures} \times \frac{m_3 - m_2}{m_1 + m_2}$$

In drawing diagram—● indicates inside focus.

In drawing diagram—* indicates outside focus, magnification m_2 .

In drawing diagram—⊙ indicates outside focus, magnification m_3 .

Fig. 3 represents the photographs with the single lens calculated above, the separation between the photographs being 2 cm.

The photographs are taken on the axis and at an angle of 5 deg., and it is especially interesting to compare them with the corresponding diagrams of Fig. 1.

The results would be more nearly in accord if the photographs were taken with the monochromatic light used in the calculations. But the results are sufficient to show the possibility of checking the calculations for the case of one positive lens.

² Zeitschrift für Instrumentenkunde, translated *The Optician*.

In the case of telescope objectives in which the crown is in front, it would be possible to check the calculated rays through the system. This is also possible whenever the lens system remains positive when any number of the back lenses are removed; thus in a double symmetrical like the Unofocal photographic lens, the results at the end of the first lens, the first combination, and the whole system could be obtained to compare with the trigonometrical results.

Fig. 4 shows the results of a test on a modern anastigmat of 150 mm. focal length. It is interesting to note the behaviour of the rays which pass out of the one plane, these corresponding to the apertures on vertical lines.

It is thus possible to obtain the aberrations of a system either by calculation or measurement, and to express them in the same diagrammatic form; but it would be exceedingly desirable to deduce from these aberrations a numerical value which should give the definition; and thus the latter could be absolutely predicted from the value of the aberrations, as calculated or measured.

There are two methods of procedure in attempting to set up such a standard; the one, purely empirical, to determine by a series of observations the aberrations which give good definitions, and the behaviour of each combination of aberrations; the other method is to determine theoretically the effect of aberrations on some important factor which we know influences the definition, such as the distribution of light intensity, and to determine how far results deduced in this way agree with observation and experiment.

An attempt at the solution of this problem has been made by Strehl and others, for the case of central definition for telescope objectives and also for microscope objectives, though in the latter case the impossibility of accurately measuring aberrations has precluded the testing of the results. But the results of the method in the case of telescope objectives have so far confirmed the theory, and it is with the hope that those of you who have the opportunity may make further tests that I give a short description of the method.

In the case of telescope objectives it is easy to determine the brilliance of the central image as compared with its possible value. In Fig. 5, F is the focus of the system, OQ the emergent curved wave, OP the spherical wave of equal curvature at O. The light proceeding from Q to F will traverse a distance QF instead of OF=PF.

And thus there will be a difference of phase at F of $2\pi \frac{PQ}{\lambda}$.

$$\text{The total aberration FN} = \frac{\sin RQF \cdot QF}{\sin QNF}$$

$$\begin{aligned} \text{But } \sin RQF &= \sin(\sigma_1 - \sigma_0), \\ &= \tan \sigma_1 - \tan \sigma_0 \times \cos \sigma_0 \cos \sigma_1. \end{aligned}$$

$$\text{The lateral aberration FN} = \frac{\sin RQF \cdot QF}{\sin QNF}$$

$$\begin{aligned} \text{But } \sin RQF &= \sin(\sigma_1 - \sigma_0), \\ &= \tan \sigma_1 - \tan \sigma_0 \times \cos \sigma_0 \cos \sigma_1. \end{aligned}$$

$$\tan \sigma_1 = \frac{d\beta_1}{dx}, \text{ where } x \text{ is the ordinate of Q, and } \beta_1 \text{ is its abscissa}$$

$$\text{Similarly } \tan \sigma_0 = \frac{d\beta_0}{dx}$$

$$\text{We have FN} = QF \times \frac{d\beta_1 - d\beta_0}{dx} \cos \sigma_1$$

$$\therefore \frac{d\beta_1 - d\beta_0}{dx} = \frac{\text{lateral aberration}}{QF} \frac{1}{\cos \sigma_1}$$

$$\beta_1 - \beta_0 = \int_0^x \frac{\text{lateral aberration}}{f} dx,$$

where f = OF and σ is taken small.

$$\text{Thus the light reaching F from Q has } \int_0^x \frac{\text{lat. aberr.}}{f} dx \text{ difference}$$

$$\text{in path, i.e., } \frac{2\pi(\beta_1 - \beta_0)}{\lambda} \text{ difference of phase.}$$

The intensity at F is proportional to the square root of

$$\left\{ \int_{x=0}^{x=h} \left\{ 2\pi x dx \cdot \cos 2\pi \frac{\beta_1 - \beta_0}{\lambda} \right\}^2 + \int_{x=0}^{x=h} \left\{ 2\pi dx \sin 2\pi \frac{\beta_1 - \beta_0}{\lambda} \right\}^2 \right\}$$

Thus from a knowledge of the lateral aberrations of the objective the brilliance at the centre can be determined as a fraction of the possible brilliance, and this is a number associated with the definition of the objective.

It would be very desirable that this theory should be subjected

to as severe a test as practicable, as the results of such tests might furnish us with a means of expressing the definition of the objective as a definite number.

The papers of Strehl give various modifications of the method, enabling it to be applied to test the best position of the focus, and to allow for this element in the final estimate of the brilliance of the

image; the calculations are much simplified by the adoption of certain graphical methods for which I must refer you to the original papers.

S. D. CHALMERS, M.A.,
Head of Department Technical Optics,
Northampton Institute.

THE EXHIBITION AND ITS CATALOGUE.

Lenses.

The large hall of the Northampton Institute is devoted to a collection of optical and general scientific instruments, arranged in classes and very fully listed and described in a most comprehensive catalogue of 276 pages. Naturally, a large proportion of space is allotted to materials and apparatus not directly photographic. Astronomy, navigation, surveying, meteorology, and microscopy are thus very fully represented. Photography and optical projection do not come in for so large a share of attention, but are, none the less, very prominently in notice. Of the lens makers, Messrs. Aldis & Prothers show the Aldis anastigmat; Messrs. R. and J. Beck the Unofocal Beck-Steinheil orthostigmat, biplanat, and telephoto attachments, with other photographic apparatus. Messrs. J. H. Dallmeyer, Limited, exhibit portrait lenses, series C and B, the Dallmeyer-Berghelm lens, stigmatic lenses, telephoto attachments, the Adon lens, and a whole series of rapid rectilinears and wide angles. J. Fallowfield and J. Lizars show portrait lenses; and Messrs. Ross, Limited, exhibit the cabinet portrait lens, the Ross Homocentric and Ross-Zeiss, and Ross-Goetz anastigmats. The Holostigmat and other lenses of W. Watson and Sons concludes the section. The catalogue will probably interest the optical student even more than the actual exhibits, as almost every lens is the subject of a drawing showing the curvatures, and accompanied in most cases by brief particulars of the glasses employed.

Shutters and Cameras.

Apparatus of this class by leading makers occupies nearly twenty

pages of the catalogue and a goodly space in the exhibition. R. and J. Beck, J. H. Dallmeyer, Limited, J. Fallowfield, Houghtons, Limited, J. Lizars, Newman and Guardia Limited, Ross Limited, and W. Watson and Sons. Most of the instruments, as also those in the "Enlargers" Section, are well known to photographers.

Optical Projection Apparatus.

As interesting a section as any is that which includes artificial lights and optical devices for projection. The Nernst lamp is prominent in the exhibits of Messrs. John J. Griffin and Sons, Limited, and Robert W. Paul; the latter firm showing some extremely compact lanterns specially designed for this form of lamp. Arc lamps, their leading features briefly summarised in the catalogue, are shown by Mr. Paul, by Messrs. Ross, Limited, by Messrs. A. and J. Smith, and John Wrench and Son. Messrs. Newton and Co. have a striking exhibit of projection lanterns, and optical lanterns of various forms are shown by several firms. Cinematographs are represented by the manufactures of only three firms: Mr. Robert W. Paul, the Prestwich Manufacturing Co., and Messrs. J. Wrench and Son.

Optical Measuring Instruments.

We ought not to omit the mention of various scientific instruments for measurements of photographic lenses, or for other measurements applicable to photographic research. The Beck lens-testing bench is exhibited by Messrs. R. and J. Beck; and spectrographs and spectrophotometers by Adam Hilger, Limited.

NOTES ON THE SECTIONS.

One feature of the catalogue which commends it to the student of optics is the introduction to each section, in each case evidently the work of a competent writer. Thus the notes introductory to the photographic section very succinctly sum up a number of points in regard to the choice of lenses, which might well be consulted by photographers as a guide in their choice of an instrument. In other respects also the catalogue is a valuable work of reference, as affording a glance over British optics of the present day. The Convention, as the president states is his preface, has one "frankly practical aim to improve

the position of the optical trade, and to increase the demand for English goods." In that object the catalogue should certainly fulfil the task expected of it. To quote Dr. Glazebrook's preface again: "It contains a classified description, not only of the objects exhibited, but of the other work of many representative firms, arranged in such a way that any one consulting it can easily find by whom the goods he is in search of are made, and where to go to see specimens, or to obtain information. Such a work, if well done, cannot fail to have a real value to the trade, and to increase in a marked degree its prosperity."

THE PHOTOGRAPHIC CONVENTION OF THE UNITED KINGDOM.

TWENTIETH ANNUAL MEETING: DUBLIN, JULY 10 TO 15, 1905.

THE meetings will be held in the Engineering School, Trinity College. The exhibition of apparatus, pictures, etc., in the Leinster Lecture Hall, Molesworth Street.

President for the year: Professor John Joly, F.R.S., D.Sc. Retiring President: G. Herbert Strutt, Esq.

Past Presidents: J. Traill Taylor, Andrew Pringle (Vice-president), C. H. Bothamley (Vice-president), George Davison (Vice-president), William Bedford, George Mason, Sir Howard Grubb, A. Haddon, H. P. Robinson, F. P. Cembrano (Vice-President), John Stuart (Vice-president), William Crooke (Vice-president), Thomas Bedding (Vice-president), Sir William Herschel, Bart., Sir Robert S. Ball, Sir Robert Pullar (Vice-president).

Members of the Council: G. B. Bainbridge, Morpeth; Harold Baker, Birmingham; Robt. Benson (Hon. Local Sec.), Dublin; Godfrey Bingley, Leeds; Henry Coates, Perth; W. J. Croall, Edinburgh; T. R. Dallmeyer, London; H. C. Draper, F.R.S., Dublin; W. E. Dunmore, London; Alfred Ellis, London; S. H. Fry, London; H. Goodwillie, Dublin; T. K. Grant, London; Dr. E. Collier Green, Derby; H. M. Hastings, London; E. J. Humphery, London; C. B. Keene, Derby; Sydney Keith, Hounslow; Furley Lewis, London; C. Phipps Lucas, London; J. W. Marchant, London; A. F. Mowll, Liverpool; John Noaks, Croydon; G. W. Norton, Oxford; Rev. T. Perkins, M.A., Blandford; Arthur Priestley, Birkenhead; Ralph Robinson, Redhill; J. A. C. Rathven, Dublin; P. R. Salmon, London; F. H. Sanderson, Cambridge; J. A. Scott, M.D., F.R.S.C.I.,

Dublin; T. Scotton, Derby; A. Seaman, Chesterfield; E. Webb Smith, Dublin; Henry Spink, Brighton; W. Taylor, Leicester; J. H. Walker, Leeds; E. J. Wall, London; H. Snowden Ward, London; Major-Gen. J. Waterhouse, I.S.C., London; S. B. Webber, London; J. B. B. Wellington, Elstree; A. Werner, Dublin. Messrs. H. A. Chapman (of Cambridge), Alex. M. Rodger (of Perth), and W. Crowther (of Derby), are by Rule XII. *ex-officio* members of Council for one, two, and three years respectively. Vice-presidents are by Rule X. members of Council *ex-officio*. Trustees: Major-Gen. J. Waterhouse, I.S.C.; Frederick Albert Bridge, Hon. Gen. Sec. and Treas.: F. A. Bridge, East Lodge, Dalston Lane, London, N.E.

Reception Committee: The Right Hon. Lord Ardilaun, D.L.; Sir Walter Armstrong, C.B., J.P., Director National Gallery of Ireland; W. E. Adeney, D.Sc., F.I.C., F.C.S., Curator Royal University; Wm. Anderson, J.P., Managing Director Dublin United Tramways Company; Charles Ashworth, M.R.I.A.I., M.I.C.E.I.; Sir Charles Ball, M.D., F.R.C.S.; Professor W. F. Barrett, F.R.S.; Arthur H. Benson, F.R.C.S.I.; Wm. Bewley, B.A.; Wallace Beatty, M.D.; James Boydell, J.P.; James Brennan, R.H.A., M.R.I.A.; Robert Browne, M.D., F.R.C.S.I.; W. H. Brayden, B.L.; Richard S. Baker, Cork; Sir Charles Cameron, K.C.B., M.D., F.R.C.P., F.R.C.S.; Professor G. H. Carpenter, B.Sc., M.R.I.A.; J. W. Chancellor; Sir Ernest C. Cochrane, Bart.; Professor Grenville A. J. Cole, M.R.I.A., F.G.S.; Alexander Conan, J.P.; Professor MacDowel Cosgrave, M.D.; F. W. Crossley; Arthur Chance,

resident Royal College of Surgeons; Professor H. Dixon; H. C. Rapier, F.C.S.; Sir Thomas Drew, President Royal Hibernian Academy; Hamilton Drummond, J.P.; Charles Eason, M.A., J.P.; John Ribston Garstin, D.L., F.S.A.; Samuel Geoghegan, M.I.Mech.E., M.I.C.E.I.; John P. Griffith, M.Inst.C.E.; Henry Goodwillie; Sir Howard Grubb, F.R.S., F.R.A.S.; H. Harrison, Dublin and Lucan Electric Railway Co.; W. S. Haughton, M.D.; Richard A. Hayes, M.D., F.R.C.S.I.; J. Hewitt; James Inglis, P. John Irwin, J.P., T.C.; Professor John Joly, F.R.S., D.Sc., President of the Convention; Sir Robert W. Jackson, C.B., F.R.C.S.I.; Wm. Lawrence; The Right Hon. the Earl of Meath; George Mansfield, J.P.; Lieut.-Col. Edward Macartney-Filigate; Professor E. J. McWeeney, M.A., M.D.; Charles J. MacCarthy, F.R.I.A.L.; Thomas Mayne, F.R.G.S.I.; Louis Meldon; Right Rev. Monsignor Molloy, D.D., D.Sc., Vice-Chancellor R.U.I.; John Cooney, J.P.; Sir James Murphy, Bart., D.L.; W. Kaye Parry, F.R.I.B.A., M.Inst.C.E.; Charles W. Pearson; James Talbot-Power, M.D.; Hugh Pollock, B.A., B.L.; Lieut.-Col. Henry Plews, General Manager of G.N. Railway; Colonel G. T. Plunkett, C.B., Director Dublin Museum; G. N. Count Plunkett, B.L., F.S.A., M.R.I.A.; George Prescott, A.M., I.E.E.; The Right Hon. the Earl of Rosso, K.P., LL.D., F.R.S.; J. Emerson Reynolds, M.D., F.R.S.; A. C. Ruthven, C.E.; Professor J. Alfred Scott, M.D., F.R.C.S.I.; George Scriven, M.D., F.R.G.S.; Walter Scott; R. F. Scharff, M.D., M.R.I.A.; Walter G. Smith, M.D.; E. Webb Smith; Leonard R. Strangeways, M.A., M.R.I.A., F.R.S.A.I.; J. Stuttard; Joseph Taplow, General Manager Midland Great Western Railway; Anthony Traill, LL.D., M.D., J.P., Provost of Trinity; James H. Webb, M.R.I.A.I.; Alfred Werner, F.R.P.S.; Berkeley D. Wise, M.Inst.C.E.; J. H. Woodworth; Professor Jas. Wilson, M.A., D.Sc.; H. Vivian Yeo, B.A., B.L.

Local Executive Committees.—Finance Committee: H. Carter Draper, Henry Goodwillie, Thomas Mayne, Sir Howard Grubb (hon. treasurer), J. A. C. Ruthven (hon. treasurer). Excursion Committee: W. W. Crossley, Grenville A. J. Cole, Dr. E. McDowel Cosgrave, Sir Thomas Drew, Louis Meldon, Dr. J. A. Scott. Entertainment Committee: Sir W. Armstrong, W. E. Adeney, James Brennan, Wm. Bewley, Dr. Robert Browne, Sir Charles Cameron, Sir E. Cochrane, Samuel Geoghegan, C.E., James Hewitt, H. Harrison, Count Plunkett, Lieut.-Col. Plunkett, Lieut.-Col. Plews, Dr. J. A. Scott, Dr. George Scriven, E. Webb Smith, Joseph Tatlow, Alfred Werner, F. V. Yeo. Press Committee: W. F. Cooper, Hugh Pollock, Charles W. Pearson, Alfred Werner, J. H. Woodworth, Robert Benson, hon. local sec.

Synopsis of Proceedings.

Monday, July 10.—Members of the Local Committee will attend at Trinity College to act as guides, and will arrange for short morning and afternoon excursions to objects of interest in the city (see notice boards). At the Royal Dublin Society's Buildings, Kildare Street: Official reception by the President, 7.30 p.m.; In the New Lecture Theatre: Presidential address, 8.0; followed by a grand conversation in the museum, musical promenade, etc.

Tuesday, July 11.—Excursion to Glendalough: Train leaves Harcourt Street Station for Rathdrum, 9.20 a.m.; cars leave Rathdrum for Glendalough, 11.15; lunch at the Royal Hotel, 1.0; cars leave Glendalough, 5.0; train leaves Rathdrum, 6.8; arrive in Dublin, 7.35. Note.—Should any members desire to visit Kingstown, they should take this opportunity of doing so by leaving Rathdrum by the 6.8, as above, arriving at Kingstown at 7.16; trains between Kingstown and Dublin are very frequent, and the journey only occupies fifteen minutes. There will be no meeting at the Convention Rooms on this evening.

Wednesday, July 12.—At Trinity College: Annual general meeting, election of Council, etc., 10 a.m.; meeting of the new Council, 11. At the Zoological Gardens: Reception and garden party by Sir Howard and Lady Grubb, 3 p.m. At the Gresham Hotel: Annual dinner and smoking concert, 7.

Thursday, July 13.—Excursion to Bray and the Dargle: Train leaves Westland Row Station, 9.45 a.m.; arrive at Bray, 10.20, visit Kilruddery by kind permission of the Earl of Meath; lunch at the International Hotel, 1 p.m.; drive to the Glen of the Dargle, 2; train leaves Bray for Dublin, 5.30; arrive in Dublin, 6.5. At Trinity College, 8.30: An illustrated lecture by Dr. E. McDowel Cosgrave on "Old Dublin."

Friday, July 14.—Excursion to Drogheda, Monasterboice, etc.: Train leaves Amiens Street Station, 9 a.m.; arrive at Drogheda, 9.47, cars to the Obelisk and Monasterboice; dinner (with tea) at Drogheda, 4 p.m.; train leaves Drogheda, 5.25; arrive in Dublin, 6.40. At Trinity College, 8.30: A paper on "The Use of Extremely Rapid Plates," by Mr. T. Thorne Baker (illustrated).

Saturday, July 15.—Morning: Short excursions to places in and around the city will be arranged as may be required (see notice boards). Afternoon Excursion to Howth, etc.: Train leaves Amiens Street Station, 1.52 p.m.; arrive at Howth, 2.18, visit the demesne of the Earl of Howth; electric tram from Howth Station, 3.18; arrive at the summit of the hill, 3.30; tea on the summit, 5.30; electric car leaves summit for Sutton, 6.31; leave Sutton, 7.1; arrive at Amiens Street, 7.25; or arrive at Westland row, 7.40 (for those leaving Dublin by night mail at 8.15).

Cheap Excursions to Ireland.

The London and North-Western Railway Company will run excursions from London, Birmingham, Northampton, Derby, and most of their provincial and country stations, to Dublin, by the short sea route (via Holyhead) on Thursday evening, July 6. Tickets from London (Euston), available for return within sixteen days, 26s. Fares from other stations from 12s. to 26s., according to distance.

Cheap excursions to Dublin will also be run from Liverpool, Manchester, Bradford, Huddersfield, Halifax, Chester, and many other stations in the vicinity of these places, every Thursday (or Friday) and Saturday in July. Return fares, 9s. 6d. to 15s. 6d., according to distance. These tickets will be available for return any day up to the following Monday week.

The Midland Railway Company will have excursions to Dublin from London (St. Pancras) and most provincial stations on their system on Thursday, July 6. Return fare from London (available for sixteen days), 22s. Full particulars, time-bills, tickets, etc., for the Midland Railway excursions may be obtained at any of the offices of Messrs. Thos. Cook and Son.

N.B.—For the advantage of those members who are able to remain after the close of the Convention, the various railway companies in Ireland will, on production of vouchers to be obtained from the Hon. Local Secretary, issue return tickets at single fares to any stations on their lines.

The Honorary Gen. Secretary has arranged with the London and North-Western Railway Company to reserve special accommodation for members of Convention by the excursion leaving London (Euston) on Thursday evening, July 6. Several Conventioners have already signified their intention to travel by this train, and Mr. Bridge will be pleased to welcome any others desirous of joining the party. Applications should be addressed: Mr. F. A. Bridge, East Lodge, Dalston Lane, London, N.E., must be received not later than Saturday, July 1, and must be accompanied by a remittance for the fare (26s.).

Passengers wishing for saloon accommodation on the steamer can obtain saloon tickets at the booking office on the platform at Holyhead—single journey, 8s.; return, 12s.

General Information.

New Members.—Ladies and gentlemen wishing to become members of the Convention should communicate with the Hon. Gen. Secretary and Treasurer, Mr. F. A. Bridge, East Lodge, Dalston Lane, London, N.E.; or the Hon. Local Secretary, Mr. Robert Benson, Claremont, Orwell Park, Rathgar, Dublin. The annual subscription is 5s.

On Monday, July 10, the Hon. Secretaries will attend all day from 10 a.m. at Trinity College. Members are requested to report themselves as early as possible; receive their badges of membership, and secure tickets for the excursions.

Signature Book.—It is desirable that members, immediately on arrival, should enter their names, full addresses, and where staying in Dublin, in the signature book at Trinity College.

Plan of Dublin.—A plan of the central portion of the city will be found at p. 8 in the handbook. Trinity College—the Engineering School of which building has been placed at the disposal of the members of the Convention—is situated on College Green. The Leinster Lecture Hall, where the exhibition of apparatus, pictures, etc., will be held, is in Molesworth Street, only three minutes' walk from the College. The position of both these buildings are distinctly shown on the plan.

Electric Tramways.—Dublin has a very complete system of tramways, and cars for all parts of the city and suburbs run every few minutes. The car routes are shown in red on the plan.

Cabs and Jaunting Cars.—A list of cab fares, etc., will be found on p. 43 of the handbook.

Excursions to Dublin.—For particulars of excursion trains from London and the provinces, see p. 17 of the handbook.

Convention Excursions.—Members should obtain tickets for these as early as possible, in order that adequate provision may be made for their comfort and convenience. With regard to Tuesday's excursion it is absolutely necessary that members wishing to go should write to the Hon. Secretaries, Photographic Convention, Trinity College, Dublin, so that the letter is delivered not later than first post on Monday, July 10.

Permission to Photograph.—Permission to photograph the following places of interest in Dublin has been obtained:—Christ Church and St. Patrick's Cathedral, Trinity College, The Castle and Courtyard, The House of Lords, National Gallery, Science and Art Museum, The Zoological and Botanical Gardens, Prospect and Mount Jerome Cemeteries, St. Audoen's Arch, St. Stephen's Green, The Royal Hospital, Pro-Cathedral, Guinness and Co.'s Brewery, and Phoenix Park.

Dark Rooms.—A list of dark rooms will be found on p. 47 of the handbook.

Notice Boards.—Notice boards will be placed in the meeting room. Members are requested to consult these daily.

Hotels.—A list of hotels, etc., will be found on pp. 44, 45, and 46 of the handbook. A summary of the charges is given, but members are advised, where possible, to obtain a printed tariff on or before arrival; there can then be no misunderstanding as to terms.

Private Apartments.—Members preferring private apartments are requested to communicate with the Local Hon. Secretary, who will forward a list of rooms, with terms, etc.

Annual Dinner and Smoking Concert.—The annual dinner and smoking concert, at which ladies are welcomed, will be held at the Gresham Hotel, Upper Sackville Street. Owing to the inconvenience caused by members not obtaining their dinner tickets until the last moment, it has been decided to close the list at 11 o'clock on Wednesday morning, July 12. Tickets (including attendance, but not wine), 5s. 6d.

Exhibition.—During Convention week an exhibition of apparatus, pictures, etc., will be held in the Leinster Hall, Molesworth Street.

Special Notice.—The times of departure of trains on the excursions during Convention week have been given as correctly as could be ascertained at the time of going to press. It is not expected that there will be any alteration; but in any case, the correct times will be stated on the excursion coupons.

THE PHOTOGRAPHIC SURVEY OF DUNDEE.

An announcement was made in March, 1903, that the project of a photographic survey of Dundee had been taken up by the Dundee and East of Scotland Photographic Society. A Special Committee was then appointed to carry out the arrangements, with Mr. O. B. Hatch as hon. secretary. The city was mapped out on a definite plan, and specific subjects were allotted to members of the society. The purpose was to have for preservation in the Dundee Museum a complete collection of photographs of Dundee at the present day. While antique buildings that still survive would be duly chronicled, modern structures that show the style of the time, churches, public buildings, streets, and all that exhibits the social life of the early twentieth century would be included.

The statement now published by the secretary shows that the total number of prints already made is about 1,000, comprising about 250 from the late Mr. A. C. Lamb's collection, which includes some 80 prints showing the building of the old and new Tay Bridges. The new bridge especially is shown in its various stages of construction, and is minutely described by Mr. Alexander Hutcheson, F.S.A. (Scot.). The most interesting and important series of the Lamb collection is the Howff. Many beautiful examples are shown. This series is specially valuable, as the carvings on the stones are in many cases to-day worn away or destroyed. Mr. A. H. Millar, F.S.A. (Scot.), has undertaken to supply the literary and descriptive matter to this section.

A fine series of whole-plate prints shows the various rooms, laboratories, etc., of the university. The exterior of the university has also been fully shown. The Industrial School, with children at work, drill, and play, has also a set of large prints of excellent quality. The exteriors of many of the Board schools and the Academies and High Schools are also included in this section, as well as a number of prints showing the system of teaching the deaf and dumb. The interiors of the High Schools and system of educating and employing the blind are at present being taken. This section is the educational side of Dundee life, and will be fully described by Professor Steggall.

The religious side of the life of the people is shown by two views of every church in Dundee—one of the exterior and one of the interior. Some thirty churches have already been done, and the remainder are expected to be completed this year.

The trades include some fine views of jute mills and the machinery used in spinning and weaving. The shipbuilding and engineering trades are presently being photographed, as also are Messrs. Keiller's and Messrs. Lindsay and Low's factories. This work would not be complete without these great industries being adequately represented. The municipal works are also being photographed during the next few months, including the Cleansing and Water Departments. The Gas Department and electric lighting system have been done, and a most complete and interesting set of views is the result. Mr. Andrew Yuill will write up the history of the Gas Department.

The streets and buildings include many picturesque and interesting views of closes and wynds with much of antiquarian and historic interest. Messrs. T. S. Robertson, F.S.A., ex-Councillor Elliott, and Alexander Hutcheson, F.S.A., have kindly undertaken to write up and describe this large section. It is satisfactory to note that this series has now almost been completed. The harbour forms another section. Many beautiful prints of large size show the docks full

of sailing craft. The four-masted jute fleet and many changes in the docks, etc., are well illustrated. Mr. Watson, the Harbour Treasurer, has kindly taken the literary and descriptive matter to this section in hand.

It is satisfactory to see such a volume of work completed in the short space of eighteen months, and great credit is due to the Dundee and East of Scotland Photographic Association for the manner in which its workers have given their time and labour to this work. The money which the Town Council has so generously given towards this work is being well spent. Without this aid from the Town Council the whole scheme must have failed.

It should be stated that all the prints are done by the largest and best firms in this class of work, and are in carbon or platinotype. The whole work when complete will be bound in one or more volumes, and presented to the Town Council for preservation and use in the Museum.

AN APPEAL TO CHARITY.

A CASE has recently been brought to our notice which, after investigation, we pass on to our readers in the belief that they will be desirous of contributing to the relief of one who has himself contributed to the progress of dry-plate photography. It is that of Mr. Peter Mawdsley, one of the pioneers in the commercial exploitation of dry plates, and now, at the great age of eighty years, ill and poor in a suburb of Liverpool. Mr. Mawdsley's name is well known to photographers of twenty or thirty years' standing, and the volumes of the "British Journal Almanac" of the seventies and eighties in the last century show him to have frequently contributed articles and notes for the information of the craft. His case was brought to our notice by Sir Henry Trueman Wood and Major-General Waterhouse, and we have ourselves learnt from the Rev. R. F. G. Smithwick, vicar and rural dean of Seaforth, Liverpool, of the necessitous circumstances under which Mr. Mawdsley finds himself at the end of a life which in the ordinary course of nature cannot be much longer protracted. We have therefore thought it our duty to bring his case before our readers: a small donation will go far to ensuring the ordinary comforts of life to one who at the end of his days is not in a position to provide them. Sir H. Trueman Wood contributes a guinea to the fund, and on his recommendation Sir Wm. Abney sends an equal amount. These, with other donations, are duly acknowledged below, and any further sums may be sent to ourselves to be handed to the Rev. Mr. Smithwick, who has interested himself in our friend's unfortunate circumstances. The following list represents the contributions already received:—

MESSRS. JAMES A. SINCLAIR AND CO., 54, Haymarket, London, W., write:—"On Wednesday, May 17, a customer of ours left a small crocodile leather bag on a seat in St. Paul's Cathedral, which contained a card case, a note book, and a Zeiss convertible protar lens, No. 3 series VIIa. The numbers of the combinations are 22,014 and 16,145. On returning to the spot where the bag was left it had vanished. If the lady or gentleman now guarding these things wishes to have honesty rewarded, we shall be pleased to pay the sum of £1 for their recovery."

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

The following applications for Patents were made between May 15 and 20:—

MEASURING PHOTOGRAPHS.—No. 10,339. Apparatus for measuring a photograph or the like both ways simultaneously at any reduction. Ernest Alfred Stidston, 29, Coronation Road, Basingstoke, Hants.

FILMS.—No. 10,372. Improvements in the manufacture of films for photographic and other purposes. John Henry Smith, 65, Chancery Lane, London.

ROLL FILMS.—No. 10,394. Improvements in roll-film photography. William Fraser Claughton, Kelly and John Arthur Bentham, 7, Southampton Buildings, Chancery Lane, London.

WASHERS.—No. 10,485. Improvements in apparatus for washing and drying photographic prints. Charles Francis Pease, 28, New Bridge Street, London.

FOCAL-PLANE SHUTTERS.—No. 10,514. Improvements in focal-plane or other roller-blind shutters. Arthur Lewis Adams, 26, Charing Cross Road, London, W.C.

PANORAMIC CAMERAS.—No. 10,569. Improvements in panoramic or other photographic cameras. John Boulton Brooks, 24, Temple Row, Birmingham.

CAMERAS.—No. 10,600. Improvements in photographic cameras. Arthur Lewis Adams, 26, Charing Cross Road, London.

CINEMATOGRAPHS.—No. 10,602. Improvements in cinematographs. Alfred Wrench, 4, South Street, Finsbury, London.

LIMELIGHT.—No. 10,603. Improvements in limelight apparatus. Alfred Wrench, 4, South Street, Finsbury, London.

COMPLETE SPECIFICATIONS ACCEPTED.

Specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

HAND CAMERAS.—No. 14,590, 1904. The claim is for a sliding block, carrying the lens of a hand-camera, which can be wholly or partly removed from the camera, and this permits of the lens being easily obtained for cleaning. The block is provided with light-excluding flanges and plate. Alfred Sidney Spratt, Tudor Works, Tudor Road, Hackney, London.

HAND CAMERAS.—No. 4,106, 1905. The claim applies more particularly to magazine cameras with shutters in which the rate of exposure is controlled by friction brakes and which require periodical adjustment through atmospheric changes or other causes, and also to magazine cameras provided with opening front doors. The improvement consists in an auxiliary opaque lens-cover or shutter, attached to a sliding rod, which projects through, preferably, the top of camera where it is furnished with a knob. The object of the lens-cover or shutter is to cut off all light passing through the lens to the magazine beyond when the exposing shutter or the door at the front of camera is opened during the process of adjustment or preliminary testing, the projecting rod serving as a signal and a safeguard against attempting exposures when the lens is covered, which has hitherto frequently happened, where auxiliary covers have been operated by turning a milled head or cranked arm. Houghtons Limited and Edgar William Houghton, 88-89, High Holborn, London.

COPYING TRACINGS.—No. 21,367, 1904. The claim is for a machine on which to print from long tracings by electric or other light. A glass plate, A, is bent to a suitable curve and mounted be-

tween two standards, B and B'. An endless band, F, of textile fabric passes between feed and discharge rollers, D and D' and E and E', over the convex side of the glass plate, A, the mechanism being driven by a drum, K, which is actuated by heavy

weights attached to the drum by a flexible coil. The escape-ment of the drum is controlled by clockwork, and there is gearing to provide for various speeds of passage of the sensitised paper. The tracing and sensitised paper are placed together beneath a guide, h, at the front of the feed-rollers, D and D', and the train set in motion. The tracing and sensitised paper are thus carried at a regular speed by the band F in close contact with each other and with the glass plate A around the convex surface of the glass to the discharge table H'. B. J. Hall, 39, Victoria Street, Westminster.

The following complete specification is open to public inspection before acceptance under the Patents Act, 1901:—
9.806, 1905. Petrie. Apparatus for developing and fixing photographic plates.

THE many friends of Mrs. Catharine Weed Ward will regret to hear that she is at present suffering from the effects of a carriage accident, incurred whilst travelling in North Devon. Her injuries, we are glad to say, are temporary, but some weeks' rest will be necessary before she is in a condition to be moved from the out-of-the-way village on the edge of Exmoor, which was the scene of the accident.

WE have received the catalogue of the International Photographic Exhibition at Genoa. It is a pretentious book of considerable bulk and undoubted originality in conception. Of a long oblong shape, bound in dark blue with terra cotta coloured leaves, it gives particulars of the 1,015 exhibits which form the exhibition, and is further embellished with reproductions of some of the pictures. The exhibition, which remains open for some time, appears to be a great success, if the number and quality of the exhibits have a bearing on the matter, as most of the best-known English, American, and Continental pictorial workers are represented.

AN exhibition of selected works, submitted in competition for art scholarships and exhibitions in connection with the London County Council (Education Department), was opened at the Medical Examination Hall, Victoria Embankment, W.C., on Friday last, May 26. Some very interesting and excellent work was on view.

New Materials.

"Bertha" Brilliant Spangles. Made by the Vanguard Manufacturing Company, Maidenhead.

In addition to supplying the photographer with a series of useful transparent colours for tinting prints and postcards, the Vanguard Company has now placed on the market a series of "Brilliant Spangles" for "Jewelling" portraits, picture postcards, and Christmas cards, etc. The spangles are composed of finely-ground and extremely brilliant metallic particles of various colours, intended to represent various styles of jewels. The set includes diamond, ruby, emerald, sapphire, and iridescent spangles, and they are applied with the aid of "Bertha" adhesive medium. For applying the spangles in fine lines or points, the "Bertha" Jewelling Tube is supplied. This is a glass tube drawn to a finely-pointed orifice. It is charged with strong gum, or "Bertha" adhesive, and drawn over the parts to be jewelled, leaving a fine line of adhesive. The spangles are then brushed over the surface, and adhere to the sticky lines. The price of the set of seven different coloured spangles in boxes is 1s. 6d., and they are good value for the money.

The "Ensign" Non-curlable Roll Films. Sold by Houghtons, Ltd., 88 and 89, High Holborn, London.

This well-known make of films, manufactured by Austin Edwards, of Warwick, is now placed on the market coated with gelatine on the back. This renders it more easy of manipulation, and is a preventive of curling when in the developer and afterwards when drying. The characteristics of the new film are similar to the older product, and are distinctly favourable to good photography. Latitude in exposure and ease of development are noticeable features, and, in our hands, exposures ranging from a very brief fraction of a second to several seconds have, where the film has been developed in its entirety, given excellent negatives, all of first-rate printing quality. It must be borne in mind by users of "Ensign" films, when drying the new variety, that nothing must come in contact with either side, as the back is as liable to abrasion as the front. Pyro and ammonia is not recommended as a developer for this film, but either pyro-soda—of which a good and reliable formula is given in the instructions that accompany each film—or hydroquinone and metol can be employed to obtain good, clean negatives, but the latter will not permit of quite so much latitude in exposure. To these notes on the behaviour of the film in outdoor work we may add the figures obtained for us by sensitometric tests by Mr. C. E. Kenneth Mees, B.Sc.

Batch No. 5736 (marked F 111 Wynne).

Inertia (i. H and D pyro-soda) .279.

This figure may be converted into the speed numbers of the various

systems by simple calculation. $\frac{34}{8} =$ the H and D number, $\frac{50}{8} =$

Watkins' number, and the square root of this latter, when multiplied by 8, gives the Wynne number. On this basis the "Ensign" film works out at F 109 Wynne, a figure which is very close to that claimed by the makers. $\gamma \infty$ (the greatest possible steepness of gradation) is 1.6. K (velocity constant of development with standard ferrous oxalate) .112, a figure which gives a time of nine minutes for a standard gradation of 1 in the standard developer. O (opacity of plate to blue light, and an index of the latitude of the plate). 10. The chief conclusions from these figures are that the film tends to softness and develops fairly quickly.

NOTICE.—In consequence of the large demands upon our space made by the report of the Optical Convention this week, a number of articles, including the concluding part of the series dealing with "Modern Chemistry," by Mr. Mees, are held over.

News and Notes.

DEATH of Horatio Nelson King.—As we go to press we regret to hear of the death of Horatio Nelson King, which took place on May 25, at the age of 75. Although not the oldest photographer in the world, Mr. King was one of the oldest in the profession, having commenced his practice in the year 1851. His business embraced an immensely wide field of portraiture and landscape, and the palmy days of the stereoscope and the view-publishing trade. He introduced the extensive series of negatives was rarely idle. He introduced photography to the railway companies, and made tours of many

THE LATE HORATIO NELSON KING.

Born, 1830. Died, May 25, 1905.

of the country in the interests of several of the great lines. King may be named as one of the pioneers in photography for the illustrated press, for his connection with it dates back to 1858, when a photograph of his appeared in the "Illustrated London News." He was early in the field when reproduction fees promised to add to the photographer's income. By his death still another link with the past is severed, for few of his compeers remain to mark his demise. He was associated in one way or another with most all the ancient fathers of the craft, and was a supporter, as he himself admitted last year, of THE BRITISH JOURNAL OF PHOTOGRAPHY from its first number.

ROYAL Photographic Society.—On Tuesday next, June 6, Miss A. Acland will deliver a lecture on "A Visit to Gibraltar, demonstrating the use of three-colour photography in giving a more favourable impression of a place than can otherwise be obtained."

AN exhibition in the East-End is projected with the object of demonstrating what can be done towards the conversion of London into a "garden city." It will probably be held at the Whitechapel Gallery during the second week in July. Models and photographs showing how successful floriculture can be applied to brighten the life of cities will be shown.

Commercial & Legal Intelligence

PHOTOGRAPHERS and the Use of Town's Water.—Mr. Mathieson, of Messrs. A. and G. Taylor, photographers, was summoned at Dewsbury on Tuesday last in respect of 10s. in respect of town's water used for trade purposes. The defendant, who said he did not live on the premises, contended that the payment he made for domestic purposes was ample. The Town Clerk, however, pointed out that if defendant used the least drop of water for the purpose of photography he was liable to pay the minimum charge for trade purposes, 10s. An order was made for the payment of the money. Mr. H. Hays, Corporation Street, appeared in answer to a similar summons. He stated, however, that he did not use water for photographic purposes at his studio. The Town Clerk pointed out that the water charges specified that a photographer must take water through a meter at 6d. per thousand gallons, with a minimum charge of 10s. per annum. Otherwise, a person could leave plates in a basin, and allow the water to run to waste. That had been done from Saturday to Monday morning, and meters were fixed to check it. Having been sworn, the defendant again stated that he did not use water for photographic purposes, and the case was dismissed.

PHOTOGRAPHIC FRAUDS.—Three charges of obtaining money by false pretences were preferred at West Bromwich last week against Albert Evans, aged thirty-seven, alias J. R. Wilson, described as a canvasser, of no fixed abode. It was alleged that the prisoner had committed a series of photographic frauds. His plan appears to have been to call at houses and obtain orders for photographs on the representation that he was canvassing for "The Midland Art Photographic Company," of High Street, West Bromwich. In most cases he obtained a deposit of 6d. or 1s., giving a receipt signed J. R. Wilson. Mr. Smith, of the Midland Art Photographic Studio, said he never employed canvassers, and had no knowledge of the prisoner. The latter was arrested at Bilston, and when shown the receipts remarked: "They are all frauds." A singular feature of the case was mentioned by Mr. C. H. Darby, who appeared to prosecute. He informed the Bench that a man named Underwood, who was convicted of a similar class of offence at West Bromwich Quarter Sessions, and was released from prison by order of the Home Secretary, suggested that the prisoner was the man who was his double, and through whom he was wrongfully convicted. The Magistrates' Clerk pointed out that Underwood was convicted for clothing frauds, but Mr. Darby said it was the same class of fraud. The prisoner pleaded "Not guilty," saying that he represented the Midland Counties Photographic Company, but the names of the two companies got mixed up. He was sent to gaol for six weeks with hard labour.

EMPLOYER and Employee.—At Darlington County Court, on Wednesday of last week, John A. Hebden, 45, Pensbury Street, sought to recover from Bertram Claudius Brown, 62, Victoria Embankment, 8s., the balance of a week's wages, and 16s., one week's wages in lieu of notice. It appears that the plaintiff had, in response to an advertisement, met the defendant, and was engaged as photographer's assistant for one fortnight at 16s. a week, and if he did his work satisfactorily he was to receive 21s. a week. He started on Monday, March 30, and worked a fortnight, and no complaint was made until the last Saturday of the fortnight, when, at four o'clock, he received 8s., and was told to call again at six o'clock for the balance. He did so, but the defendant did not appear. He met him later, when defendant said he would not pay him, and that he would have to take him to the County Court first. The defence was that the plaintiff had wasted £3 10s. worth of material. The Judge made an order for payment forthwith.

HEAVY Penalty for a False Description.—At the Clerkenwell Police Court, on May 23, Messrs. Fordham and Co., 9, Lensden Place, Fins-

bury, appeared before Mr. d'Eyncourt in answer to three summonses taken out by the Great Northern Railway Company, charging them, on February 10 and two other dates, with "being the owners of photographic mounts, consigned to firms at Manchester, and having been brought to King's Cross Station for conveyance by the railway, did unlawfully give to the collector of tolls for the company a false account of such goods, by falsely describing the same as cardboard, with the intention of avoiding the payment of the true tolls." The defendants pleaded guilty. Mr. J. P. Grain prosecuted on behalf of the Great Northern Railway Company, and said the defendants forwarded on three occasions packages of photographic mounts under the description of cardboard, which was charged at a much lower rate. Whereas they should have paid 12s. 3d., 7s. 5d., and 7s. 5d., they were only charged, under the false description, 7s., 4s. 4d., and 4s. 4d. As an instance of the wholesale manner in which railway companies were defrauded in this way, counsel mentioned that recently a large number of parcels were examined at various London termini, and 90 per cent. were found to be falsely described. Mr. d'Eyncourt inflicted a penalty of £30 and 25 gs. costs.

EASTMAN KODAK COMPANY of New Jersey.—The annual quarterly dividends of 1½ per cent. (being at the rate of 6 per cent. per annum) upon the outstanding Preferred stock, and of 2½ per cent. (being at the rate of 10 per cent. per annum) upon the outstanding Common stock, have been declared by the Eastman Kodak Company of New Jersey, payable on July 1, 1905, to stockholders of record at the close of business on May 31, 1905.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

June.	Name of Society.	Subject.
3.....	Manchester Amat. Photo. Soc.	Chetham College. Mr. J. J. Phelps.
3.....	Watford Camera Club	Berkhamsted Common.
3.....	Hull Photographic Society	Bolton Woods.
3.....	Glasgow Southern Photo. Assn.	Scottish Photographic Federation Excursion to Blairgowrie.
5.....	South London Photo. Society...	Special General Meeting. A Paper by Mr. C. H. Oakden, F.R.P.S.
6.....	Royal Photographic Society ...	"The Negative in Three-Colour Work." Demonstrated. Miss Acland, F.R.P.S.
6.....	Sheffield Photo. Society	"Photographic Chemistry." Mr. J. Gilbert Jackson, M.P.S.
7.....	Cricklewood Photo. Society.....	"Hints on Outdoor Photography." Mr. W. Emery and Members.
7.....	North Middlesex Photo. Soc. ...	Lantern Slide and Print Competitions.
7.....	Edinburgh Photo. Society ...	Forty-fifth Annual Meeting.
8.....	London and Prov. Photo. Assn.	"Gun Printing." Mr. C. H. Hewitt.

CROYDON CAMERA CLUB.—May 24. Mr. C. H. Hewitt gave a most interesting address on portraiture, and although most of his hints and suggestions mainly referred to artificial lighting, still many of them were equally applicable to daylight illumination. The president, Mr. W. H. Smith, placed at the disposal of the lecturer an entirely new model of his oxy-magnesium lamp, possessing a universal movement, and a number of excellent portraits were taken during the evening by its aid. Mr. Hewitt prefaced his discourse by disclaiming any intention of treating the matter from the "art" side, and created some amusement by describing the various stages the raw amateur frequently passed through, in trying to record the features of his, or her, friends and relations. As a start, the unfortunate sitter was more often than not, placed sideways to a window, with the line of sight and direction of light at right angles to each other, the natural consequence being a face black on one side and chalk white on the other. This hybrid presentment was generally attempted to be remedied by the introduction of a reflector, so large as to be almost as powerful as the source of light itself, and produced such glaringly false illumination, that on the third shot the

"patient," as a forlorn hope, was placed directly facing the light with the camera in the window. This resulted in a maximum of flatness. The thinking worker adopted a middle course and placed his sitter at an angle of 45 degrees to the source of light, better modelling or roundness of light and shade, with a sufficient amount of contrast being thereby obtained. The "reflex" spots in the eyes also approximated the same relative position, and this was important. Speaking of "eyes," Mr. Hewitt went on to say, great care should be taken not to let heavy shadows obtrude themselves, and more natural drawing was obtained by allowing the more-distant eye to fall a little lower on the plate. As to the question of contrast, he had found that sitters usually preferred too little contrast than too much. The crudeness of the direct light could be softened in three ways, either by a reflector, or a semi-transparent, or diffusing screen, interposed between the sitter and the light, or a combination of the two. With a reflector, in inexperienced hands, there was the ever-present danger of false illumination. Its best position was generally in advance of the sitter, and inclined at a suitable angle, not directly on one side. A reflector, whilst softening the contrasts, did not diminish the intensity of the high lights. A diffusing screen was, perhaps, to be preferred, if placed close to the sitter and away from the light, the softer the contrasts and vice versa. A diffusing screen, unlike a reflector, in all cases lowered the actual intensity of the high lights. Sometimes an oily skin would produce a high light distinctly out of place; in such a case a little powder might with advantage be brought into requisition. At the conclusion of Mr. Hewitt's exposition, the president passed round a portrait lantern slide made by Mr. Kenneth Mees. The interest which it aroused did not centre exclusively in its pictorial qualities, but rather in the method of production of the original negative, which was on a Wratten speed plate, sensitised with homocol. The exposure was half-a-second at f3.5, the sitter being 3 feet from an ordinary incandescent gas jet. The following facts in reference to a particular plate bathed in homocol are also of interest:—

"Speed" plate	288 Watkins.
"Speed" plate (bathed in homocol).....	448 Watkins.
Sensitiveness of bathed plate to blue	2
Sensitiveness of bathed plate to yellow	1

KETTERING CAMERA CLUB.—The first of a series of photographic excursions arranged by the committee of this club took place on Saturday last, when about twenty members availed themselves of the invitation of Sir Arthur de Capell Brooke, Bart., who is a patron of the club, and visited Great Oakley.

LEEK PHOTOGRAPHIC SOCIETY.—This society, which has been established about two years, opened their first exhibition in the Nicholson Institute on Thursday evening of last week. The exhibition was opened by Mr. A. H. Moore, who expressed the pleasure it gave him to attend and see such admirable pictures round the walls. Mr. Robert Hall had several striking photographs, the most admired being "Twice Once a Home," an old untenanted cottage on the way to Rudyard, and "Nancy Study." In Mr. V. Prince's collection were several local views and pictures of cathedrals, the most noticeable being that of "The Abbey Tower, Tewkesbury," and "Tissington Spires, Dove-dale." Mr. E. Howarth had a fine view of "The Fireplace, Moreton Old Hall," and Mr. W. Hill had a good photograph of Cheddleton, taken in the early morning. Mr. H. A. Blades exhibited good pictures of "The Roar of the Waves," and "The Chancel of St. Luke's, Leek." Mr. C. F. Depree showed an interesting study in "Eyes of the Soul." Mr. Nithsdale had a number of views of the district, and other exhibitors were Messrs. S. T. Johnson, J. C. Miller (of the "Old Church, Rush-on"), W. E. Brindley, J. K. Hyde ("The Interior of St. Mary's, Leek," and the "Old Wooden Horse"), C. Brassington, J. Marsden, T. Wardle, D. Fergyson, and J. W. Sutton.

BARROW NATURALISTS' FIELD CLUB.—The first outing of the newly-formed Thursday photo-section of this club took place on Thursday last week to Cartmel and Holker, when several members took advantage of the opportunity of visiting the Priory for photographic purposes.

THE FEDERATION OF THE PHOTOGRAPHIC SOCIETIES OF NORTHUMBRIA AND DURHAM.—The annual report of the federation shows that the successful year has been passed, and that the total membership is over 800. The questions of holding a field day and also a large photographic exhibition in Newcastle have been abandoned for the present, but it is proposed to hold a dinner and social evening at some suitable centre later in the year. "The Federation Record" has completed its first year of publication, and reflects much credit on its Editor, Mr. R. Borrow, and its business manager Mr. S. Thomson, through whose efforts it has been successful, both from a literary and financial standpoint. The finances of the federation are in a satisfactory condition. The federated societies are as follows:—Bishop Auckland, Haydon, Consett and District, Crook and District, Darlington, Gateshead, Gateshead Teachers N.H. Society, Hartlepool P. and S., Jarrow and District, Newcastle-on-Tyne, and Northern Counties, Seaham and District, South Shields, Sunderland, and Borough of Tynemouth. All communications in connection with the Federation should be addressed to the secretary, Mr. J. B. Scott, 1, Bedford Terrace, Bedford Street, North Shields.

THE Hull Photographic Society's outing last Saturday, to Thornton Abbey, was very successful. Architectural and pastoral studies constituted the bulk of the work done.

ABERDEEN PHOTO ART CLUB.—The Photo Art Club held its quarterly business meeting at 62, Fonthill Road on May 26. It was decided that the club, during the quarter, should visit the following places:—Cove, Waterton Braes (Ellon), Cowie (Stonehaven), Fintray, Nicholls Rocks, Udry Castle, and Crathes Castle. It was agreed that the competitions remain as arranged last quarter—namely, best slides of castles of Aberdeenshire, best print illustrating Tennyson's "Brook," and best slide and print taken from negative of Thursday excursions. There were an unusual number of entries in the monthly competition. Messrs. David and Findlay, the judges, awarded them places as follows:—Prints, Mr. Clerihew, Miss M. R. Smith, Miss Smith, and Mr. Dalgety (equal); slides, Miss Dalgety, Mr. Dalgety, Miss M. R. Smith, and Mr. Bow (equal). Mr. Christian gave a demonstration with acetylene, showing what comparison it bore to the oxy-hydrogen light.

PURCHASERS of "Glazeit," the new preparation for P.O.P., announced elsewhere in our pages, are being asked to accept certain nuances. The first order opened in reply to the advertisement entitles the applicant to one of Butcher and Sons' cameras, and the next entry will receive a box of plates.

DEATHS in a London Studio.—Mr. W. J. Le Couteur, known in connection with the Amateur Photographers' Association, Brook Street, London, W., and his wife were found dead there on Wednesday morning of last week. They did not reside at the premises in Brook Street, but Mr. Le Couteur was seen in the neighbourhood late on Tuesday night. When the studio was opened a smell of gas was noticed, and inside a small room, sitting near a gas stove, were Mr. and Mrs. Le Couteur, dead. Four of the taps of the gas stove were turned on. On the table in the room was a glass containing some chromate of potash solution, but at the inquest the evidence showed that none of this had been drunk. Both Mr. and Mrs. Le Couteur were known to be in financial difficulties, although witnesses stated they had a splendid connection, but appeared to be lacking in business instincts. The jury returned a verdict of "Suicide whilst in a state of unsound mind in each case."

Correspondence.

* * *Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

* * *We do not undertake responsibility for the opinions expressed by our correspondents.*

PANORAMIC CAMERA.

To the Editors.

Gentlemen,—I have seen a camera, which I believe was made in Italy by Luino and Co., that is designed to take a panoramic view of an entire circle, to do which the camera revolves. Can any one give me the address of the makers or of their English agents?

PANORMOS.

PREPAID POSTAGE?

To the Editors.

Gentlemen,—In the *BRITISH JOURNAL OF PHOTOGRAPHY* of May 26 is proclaimed that the poor workman—in or out of employment?—should, or has to pay, "postage both ways" for specimens he may submit in and with an answer to an advertisement in "Situations Vacant."

This is levying a tax on a poor fellow who cannot help himself; this demand is also questionable, and even unjust.

The case is plain:—Two parties enter into communication, and each party is wanting or is offering something in exchange—viz., money for work or work for money. Both parties are logically under the same obligations to each other, and should therefore pay their own share in postage rate. Anything else is simply an imposition of the stronger on the weaker.

Your advice is legitimate if specimen and offer of work are submitted to a party without being first asked to do so.

I should like to see the Masters' Association give their view on this matter.

May 28, 1905.

AUDACIOUS.

THE COBALTAMINE REDUCER.

To the Editors.

Gentlemen,—Regarding your reference last week to my article in the *PHOTOGRAPHIC JOURNAL* on "Cobaltamine Reducers," may I point out that I was particularly careful to compare these with the reducers at present used in general terms only, preferring to leave it to others to decide whether the compounds I have recommended are more selective in their reducing action than any particular one of the reducers known up to now. I certainly mentioned ammonium persulphate in the above article, but only as regards its use with cobaltamine solutions in place of a plain diluted acid alone. It was its use in this respect that I found unsatisfactory. I had no wish to appear to depreciate the value of any reducer at present in use, by comparing it unfavourably with a cobaltamine reducing solution, but at the same time, since your reference may be read in this light, I may perhaps be pardoned for mentioning the fact that my experiments with a Chapman-Jones plate-tester tend to show that ammonium persulphate attacks the lightest deposits to a greater degree than an acidified solution of Erdman's salt, for instance.

With reference to your remark as to the inadvisability of using sulphuric acid of $7\frac{1}{2}$ per cent. strength, may I say that I point out in my article that hydrochloric or nitric acid may be used in place of sulphuric acid. It is agreed, I believe, that this strength of nitric acid has no harmful effect on the gelatine. Apart from this.

however, I have not found in my experiments that sulphuric acid of this strength has a bad effect on the film.

Most of my experiments carried on during the last winter and early spring gave no indication of trouble from frilling. Latterly, however, the temperature of the tap-water being considerably higher, I have experienced a few cases of frilling, but nearly all where the negative was developed, fixed, and washed, and reduced at once with a cobaltamine solution, without being allowed to dry. I do not find any trouble from frilling with negatives that have been allowed to dry before being reduced, and have not had any trouble with films at all.

In any case, during the warmer weather, I find that the ammonia bath may be reduced to 5 per cent. strength, or even less, with advantage, in which case, unless the plate is left in the ammonia bath too long, no trouble from frilling should be experienced.

Negatives may, of course, be treated with formaline or alum to prevent a tendency to frill, and I do not find that negatives so treated take appreciably longer to reduce.

I may say that I have tried many reagents in place of the ammonia, but none of them seem to possess its double advantage of clearing a slight deposit (which I believe to be a silver salt) from the film which may often be noticed, and at the same time neutralising any trace of acid left in the gelatine, forming a soluble salt easily washed out. Perhaps I may mention that this process of reduction forms the subject of a patent application, and suitable cobaltamine salts will probably be put on the market shortly.—I am, gentlemen, yours faithfully,

H. E. SMITH.

May 26, 1905.

PLATINUM PRINTERS' CATARRH.

To the Editors.

Gentlemen,—We have been considerably interested in your letter from an "Old Platinum Printer" in the current number of your journal. One of our own printers, whose attention during the last year has been given to platinotype work almost entirely, has developed all the distressing symptoms mentioned by your correspondent. Medical treatment has apparently been useless—the printer has now had to give up work entirely and go to the country for a prolonged rest in the hope of ultimate recovery.

These cases may be nothing more than coincidences, and we may say that we had no thought of placing the cause of the trouble to platinotype paper till we noticed the curious incidents mentioned by your correspondent.

It would be interesting to know whether any further cases have been observed, and such cases may be, of course, comparatively rare, just in the same way that only certain constitutions are effected by metal poisoning.—Yours faithfully,

JAMES A. SINCLAIR AND CO., LIMITED.

May 26, 1905.

LOCAL CUSTOMS AND PHOTOGRAPHY.

To the Editors.

Gentlemen,—With regard to your remarks in last week's "Ex Cathedra," as to recording some of the old customs, may I say that the National Photographic Record Association have already received many photographs of such subjects, principally taken by the president, Sir J. Benjamin Stone. The ceremonies photographed include "The Distribution of the Maundy Gifts, April 7, 1898"; "Locking the Tower Gates"; "The 'Well Dressing' at Tissington, Derbyshire"; "The 'Mops' Fair' at Stratford-on-Avon and at Bidford"; "Procession, etc., at the Shakespeare Festival at Stratford-on-Avon, 1900"; "Ceremonies in Connection with Tynwald

Day, Isle of Man"; "The 'Furry Dance' on Flora Day, Helston, Cornwall"; "The Pole Fair at Corby, Northampton"; "The Eisteddfod held at Bangor in 1902"; "Clipping the Church, Painswick, Gloucestershire"; "May-Day Customs at Knutsford, Cheshire"; "Hock Tide Proceedings at Hungerford, Berkshire"; "Collecting the 'Wroth Money,' Knightlow Hill"; "The Sports at Inverness, 1903"; and "Of Beating the Bounds." Needless to say, I shall be glad to receive further prints of other local or ancient ceremonies.—Yours truly,

GEORGE SCAMMELL,

Hon. Sec. National Photographic Record Association,
21, Avenue Road, Highgate, May 29.

PHOTOGRAPHIC COPYRIGHT IN FRANCE.

To the Editors.

Gentlemen,—I enclose you a translation of the recent decision of the Tribunal at Paris respecting photographic rights. I have translated it from "Le Journal" of the 25th inst., as I thought you might like to insert it in B.J. I think you will find it rather interesting as showing the French sentiment towards artistic work—that it should be protected, and the photography was capable of artistic work.—Yours truly,

W. R. KENNAN.

Arcachon, May 26, 1905.

The report is as follows:—

"The Seventh Chamber of the Civil Tribunal, presided over by M. Salvador, has just decided an important point relating to copyright in photographs. The question has been raised as to the right of photographs to be regarded as works of art, and to be therefore entitled to protection under the Act of 1873. The ownership of a copyright in a photographic portrait was also discussed.

"The decision of the Tribunal is that the point at issue is not to separate examination of every photograph as to whether it is a work of art or not, but the recognition of photography itself as an art. It is held that the achievements of photographers entitle them to be classed as artists, and that therefore their works should be accorded protection under the law of artistic copyright.

"As to the ownership of the copyright of a portrait, the Tribunal has ruled that, in the absence of special agreements, granting the ownership of the negative to the sitter, the latter should not assign copyright without the consent of the photographer."

[We will refer to this matter further in our next issue.—EDS. B.J.P.]

A GOOD MOUNTANT.

To the Editors.

Gentlemen,—I have frequently seen inquiries in the "Answers to Correspondents" column of the B.J. for a reliable paste for mounting photographs—and, moreover, one that will keep and be always ready for use. Starch paste is, of course, usually first favourite with professionals who have a lot of mounting to do, and who do it regularly; but even then the amount of moisture present in ordinary starch paste always tends to make even the stoutest mounts bend or cockle—especially when the prints are mounted wet.

The dry-mounting process appears to be an ideal method, but the price for a large installation is against its use in many studios. A paste that contains a minimum of moisture and great adhesive qualities, is easily applied and soon dry, and keeps ready for use is, definitely, is, therefore, likely to be of considerable advantage to many photographers. I make such a paste myself—very cheaply—and perusal of Mr. Ellington's letter in last week's B.J. tempts me to send the formula to you in the hope that it may prove of service to some of your readers. I take a pound of the best white dextrine—obtain

sible from any chemist at about 6d.—and mix it with sufficient cold water to make a stiff paste. Do not add the water to the whole of the dextrine, or an unmanageable clot of very lumpy paste will result. Stir a little water in a little of the powder at a time until all is mixed. When the pound of dextrine is a paste, free from lumps, add half a pint of cold water and a few drops of oil of wintergreen or cloves and stir well. Then pour the whole mixture into a clean enamelled saucepan and bring to the boil. When boiling, the solution will be like thin clear gum. It should then be poured into pots, covered up, and put away in a cool place to set. This takes from twelve to twenty-four hours, and the paste is then quite hard and white—like lard in appearance. Its application to the backs of prints is easily accomplished with either a stiff brush or the fingers, and very little is needed, as a small quantity can be spread over quite a large surface like grease. I have found it as sticky as any paste I know, and it is, I think, quite pure, and has no ill effects on the most delicate prints. The only thing to remember when buying the dextrine is to ask for the best white. If an inferior quality, or brown dextrine is used, the paste will not set when cool, but remains in the consistency of treacle.—Yours truly,

DERBYSHIRE.

[We are much obliged to "Derbyshire" for his letter. The method of paste-making he advocates is not new, but we can recommend it as being quite reliable. We are pleased to note that our Editorial in the B.J. for May 19, on an Editorial Millennium, is having some effect, and shall be glad to hear from readers who have hints and methods of their own practice that they can communicate for the benefit of other readers of the B.J.—Eds., B.J.P.]

"TABLET" Pyro-metol Prize Competition.—The large number of entries and the high artistic and technical merit of much of the work submitted in connection with this competition have rendered the task of judging extremely difficult. Messrs. Burroughs, Wellcome, and Co. inform us that they are engaged in making the final selections, and will announce the names of the winners at an early date.

ROYAL Portraits Rejected.—Mr. Henry J. Brooks, the well-known artist, entered an action in the King's Bench last week against the Committee of the United Service Club to recover £700, the alleged agreed price for a pair of full-length portraits of the King and Queen. The defence was that the portraits were painted subject to the approval of the Committee, and that this approval was not obtained. There being no evidence to go to the jury on this point on the plaintiff's behalf, Mr. Justice Wills entered judgment for the defendants, saying that he was sorry Mr. Brooks had entered into a contract containing such a condition.

It often becomes necessary to decide what is 20 ft. or 20 yards or 200 yards distant, and it is a most difficult task for a beginner to undertake observes a writer in the "Oxford Chronicle." One rough way is to pace out the distance in long strides, when the total steps will be (roughly speaking) the number of yards. This, however, is a rough task when 200 yards is the distance. We pity the man who has to pace 400 yards (for he must return to his base) for one calculation. For ladies, too, the yard strike is inconvenient and inelegant, and likely to attract attention and amazement. Besides, one cannot "pace" off of Strassburg Cathedral tower to estimate the distance of the nearest roofs. This difficulty of judging distances has to be faced by the soldier—or at any rate the officer—and "trial and error" can alone secure final efficiency. Take the road you are now in. Find the width of it from your door, from your window, to the opposite pavement, and to the opposite doorway. Measure distances down the road at an angle. By conning all such distances over, before and after correction, and applying the data to other streets and other places you will soon learn to judge all distances.

Answers to Correspondents.

. All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C. Inattention to this ensures delay.

. Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

. Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington Street, Strand, London, W.C.

. For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED :—

RETOUCHING.—Enclosed please find printed and toned specimens of my retouching. 1. I am a beginner, and am told that my work is too closely done. 2. My usual time for a head such as enclosed is half-an-hour. 3. I have been practising for about four months, and I am told that I have improved a great deal. 4. Should be pleased if you would publish in your journal any faults you can see; also what salary I could get?—HOPEFUL.

1. Your retouching is too minute and ineffective on the man's face, and not nearly fine enough on the women. 2. Time taken is insufficient for the best finish on such faces as sent. 3. You have not done badly for the short period you have been studying, but you have much to learn yet. 4. Your faults consist in leaving too many edges of light and shade, and general raggedness of texture. You need finishing lessons. You did not forward prints before retouching, so we cannot comment upon the treatment of the likeness—a vital point. Your retouching should command about 25s. per week, when you have improved your solidity of texture as suggested above.

FOREIGN PERIODICALS.—Would you kindly give me, through the medium of your paper, the names and addresses of the Swiss, German, and Austrian photographic journals or publications?—E. GROMANN.

You will find a full list in the "British Journal Photographic Almanac."

INSTRUCTION IN ENLARGING.—I shall be very grateful to you if you will be kind enough to inform me whether there is a private or public institute where I could learn enlarging of photographs in all its branches during the summer months.—A. CEIFER.

The Photographic School, Polytechnic, Regent Street, W.

UNDECIDED.—You do not state the purpose for which you require the camera. If for general all-round photography in addition to hand-camera work, you will probably find No. 3 the best. If bulk and handiness are considerations No. 1 can be recommended. No. 2 is, of course, the same as No. 1, but with more convenience in the shape of extra extension and square reversing back, which would be useful if the camera was used much on a tripod.

COPYRIGHT.—Some twelve months ago you were kind enough to get copyrighted for me a photograph, and I now find that another photographer had made enlargements from it and sold them five or six years ago. I shall be glad of your opinion as to whether I have any legal claim against him for selling the photographs before the negative was registered.—EQUITABLE.

You have no claim whatever for anything done before the copyright was registered. You can now prevent any future copies of the picture being made, either as enlargements or otherwise.

D. BOOTH (Nice).—The views of the Riviera do not interest us, as we are not publishers of photographs. But perhaps one or other of the postcard firms would be glad to take them up.

HAND-CAMERA QUERY.—I am having my quarter-plate stand camera fitted with rapid lens and shutter in order to enable me to take snapshots. Will you please tell me:—1. If the finder, fixed on camera, must be of the same focal length as the lens in order to secure the amount of subject shown on the focussing screen of camera? 2. As I desire to do accurate work, is a focal plane shutter the best to use, and is it, or is it not, liable to render moving objects out of proportion?—**FOCAL PLANE.**

1. The focal length of the finder lens need not be the same as that of the lens of the camera unless it is desired to use a finder giving a view the same size as that which appears on the ground glass of the camera, which would amount to using another full-sized camera. The best form of finder for snapshot work is the direct-vision finder, which is either a plain wire frame—proportionate in size to the plate used—or a rectangular plano-concave lens mounted in a frame and fixed to the top of the camera. The view is seen in miniature when looking through this lens, and aiming is assisted by a sighting pin at the rear. Most photographic dealers sell these direct-vision finders. They are quite cheap and easily fixed. 2. A focal-plane shutter will probably give you all that any other form of shutter is capable of, in addition to which it possesses much higher efficiency. It admits of a quicker exposure or a smaller stop with a given amount of light than any other shutter; and except in very exceptional circumstances, there is no appreciable distortion when using it.

ENAMELLING POSTCARDS.—Can you give me any information how to enamel large quantities of P.O.P. postcards? I have tried squeegeeing them on large sheets of plate glass which have been cleaned with a solution of spermaceti and benzole, and also with French chalk, but I find a difficulty in getting the cards off, although I dry them between washing and enamelling. Ordinary unmounted prints come off the same glass prepared in this way with ease, the postcards and paper being the same

make in both cases. If you could oblige me with a sure and quick method of enamelling same I should feel obliged, as I have to turn out large quantities at a time?—G. B.

There is no quicker method of enamelling the postcards than that which you are employing. If you harden the gelatine surface by treating the postcards to a bath of dilute formaline (10 per cent.) after fixing, and then squeegee them on to the prepared glass, immediately after taking from the final washing water, they ought to drop off as soon as dry.

A. H.—You do not state whether you used the solution after the negatives; if so, it would naturally be weakened. Try a freshly-made solution.

E. A. BARTLETT.—The stains are probably due to your not using enough hypo. There would be no difficulty in intensifying with mercury. You could probably remove the stain with 5 per cent. solution of sulphite. For such subjects you should use a slow film, either process or photo-mechanical, with a well-restrained hydroquinone developer. With regard to the copying of the glass positives, see article in our issue for April 21, p. 303.

ASSISTANT AND OTHERS.—In our next.

COPYRIGHT.—Kindly inform me in your next whether anyone could legally object to the issue of a photograph of a street view simply because their own portrait happened to be in it, being taken instantaneously while they were walking near.—**FOCO.**

They cannot, unless the photograph is libellous.

THE TYRANNY OF THE CAMERA.—In the old days, when special artists used to be sent to make a sketch of the lawn at Ranelagh or Hurlingham, the Enclosure at Ascot, or some special function graced by the presence of Royalty and smart folk, we possibly may have got less accurate pictures, but at least they made people look their best. Now that all such scenes are snap-shotted we get, writes Ambrosia in the "World," the most unbecoming studies of well-known people. We see how badly this one was walking, how shockingly another holds her arms, while the wind catching another's dress at the psychological moment gives her the appearance of being lop-sided. Men generally seem to be walking as if treading the tight rope or under the influence of severe pain. The King is caught sometimes in the act of taking a step forward which gives him the appearance, in an illustration, of playing at hop, skip, and jump.

BON VOYAGE.—Mr. William Gamble, editor of "Process Work" and the "Process Year Book," is at present in America. We are certain he will have a good reception at the hands of our cousins across the pond, and expect him to come back brimful of information as to how process is done in the States.

*** * NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

EX CATHEDRA.

Danger in the Dark Room.
The note by Mr. J. B. B. Wellington which we print on another page draws attention to a point which is certainly worthy of notice. Advocates of sulphide toning in the warmth of their encomiums of the process have laid too little emphasis on the fact of the escape of sulphide vapours from the final solution. It has been stated that a neutral solution of pure sodium sulphide is perfectly odourless, but we have never met with one which was beyond reproach in this respect. Delicate a test of danger as the organ of smell is, it must be remembered that the action on plates and papers of traces of hydrogen sulphide in the air is cumulative, and infinitesimal discharges of the deleterious compound from the sulphide bath may have their effect on the photographer's stock of sensitive material before very long. We suppose anybody with even an elementary knowledge of chemistry will have had this danger in the back of his mind, but Mr. Wellington's warning, coming as it does from one whose writings have never outrun his experience of the facts, should confirm the practisers of sulphide toning in more carefully guarding plates and papers.

Diffusing Screens.

We referred lately to the danger of getting, with the brighter summer light, contrasts beyond the compass of the plate. The landscape photographer must, of course, expose for the shadows, and develop for the high-lights, and it is almost certain that the brighter portions of his picture will be over-exposed. In portraiture, contrast is almost completely under the photographer's control, and it is one of the aims in lighting so to arrange things that by the time the shadows are exposed the high-lights will not be over-exposed, or at all events, not sufficiently over-exposed as to produce any flattening. We do not think the value of moveable head screens or side screens is sufficiently recognised in this direction. Light-coloured muslin diffusing blinds, close

against the glass roof, may soften the light and consequently the contrast in the subject; but the actual degree of softening in each particular instance is not under control to anything like the same extent, or with the same ease, as when the distance between the diffusing screen and the subject can be varied at will.

A Flashlight Lawsuit.

In the District Court, Sydney, New South Wales, damages of £5 were granted to a photographer who had been supplied with a flash powder in place of pure powder magnesium. On using the mixture in a flash lamp he sustained slight injuries to his face, and the lamp was impaired. His claim for damages was £200, a somewhat large amount considering that his injuries did not prevent him from attending his place of business the following day. In granting £5 damages the court declined to allow the plaintiff his costs, and hence he is probably out of pocket by his action. The case is one which photographic dealers may bear in mind. And, indeed, the incident, like many others in which large damages are claimed, is not without its lesson to photographers in general. In cases of copyright infringement, which frequently come under our notice, the photographic plaintiff will depreciate his own claims by putting fancy figures on the value of photographs which have been reproduced without permission. No sooner does a photographer imagine he has a publisher "on the hip" than he develops a tendency to extravagant demands. Such over-reaching policy frequently fails in its purpose, and our advice that a more reasonable tone should be taken is penned as the result of having had under our notice, only within the last few days, a case in which the photographer would have been several pounds in pocket by so doing.

Photographic Copyright in France.

The recent decision in a civil court as to photographic copyright in France gives some measure of definition to the law as it stands at present in that country. The translation from "Le Journal," which we appended last week to our correspondent's letter, was a fairly free one, and it would appear that the decision of the court is capable of a narrower interpretation than that: Photography is an art; therefore photographs are entitled to share in the protection granted to works of art. The actual French text runs:—"Le tribunal a décidé qu'il n'avait pas en l'espèce à examiner si toute photographie était une œuvre d'art, mais que le photographe devait être considéré en raison de sa notoriété, de ses œuvres et de son passé artistique comme un artiste; que, par conséquent, ses œuvres devaient être protégées par la loi (1793) en question." The passage may be applied thus:—Monsieur X. is known to be an "artistic" photographer; therefore, photographs by him are entitled to protection; which is not very much

better than the present state of things, in which the courts decide the claim of individual photographs to be works of art. If the only effect of the decision is to shift the point at issue in a case from photographs to photographers, there is not, we think, very much to be said for it. The present ruling is inequitably favourable to the established men, and makes it difficult for a young and rising photographer to obtain protection of his works. But apparently the decision is that of a minor court, and may be reversed. The just course, it seems to us, is to admit photographs as "works of art," and to grant to them the protection provided by the Act of 1793. The further ruling of the court, that the copyright of a portrait taken in the ordinary course of business is partly vested in the photographer, strikes an English reader as extraordinary, and it will be interesting to hear of cases in which it is sustained.

POISONS USED IN PHOTOGRAPHY.—II.

IN recurring to the subject of the chemicals used in photography it should be mentioned that, with the exception of a very few, they are all of a more or less poisonous nature when taken internally. Pyrogalllic acid is a poison, though it is not generally looked upon as being one by the majority of those by whom it is employed. Yet we remember, a few years back, the case of a lady's death from drinking a solution of pyro which her husband, an amateur, had mixed for photographic purposes. So far as we are aware pyro *pure et simple* has no ill-effects upon the skin, except the stain it produces. When it is used with caustic alkalies the case may be different, but the effects are not serious.

Nearly all, if not all, the newer developing agents are poisons, some more deadly than others. It is not, however, our intention to deal so fully with the poisons used by the photographer as regards their toxicological properties when taken internally, as with the effect they may have on users by contact with them in the ordinary course of their employment, and that varies greatly with different individuals.

Some persons, for example, may use many of them with impunity, while others can scarcely touch them without experiencing inconvenience. Curiously enough it does not follow that because any particular substance may affect one individual that it will every one. A solution of cyanide of potassium, as employed in fixing wet collodion negatives, is used by very many with impunity, yet the use of metal by some of those in a very short time produces trouble. On the other hand, the cyanide may affect those who are immune to the action of metal. The same may be said with reference to most of the other chemicals of an injurious character—such is the idiosyncrasy of the human system.

The deadly effect of cyanide, when taken internally, is well known, and need not therefore be specially referred to here. With the exception of the case referred to a few weeks back we have never heard of a fatality due to this poison from external contact. In this instance it was through a wound on a finger. In wet-collodion days it was quite the usual thing for the workers, whose fingers had become badly stained by silver bath, to take a lump of cyanide, moisten it with water, and then well rub the stained parts with it—quite regardless of small scratches or abrasions; then following on with pumice stone or sand. This is what might well be looked upon as a dangerous practice, but it was the one generally followed by operators, and by printers, for removing silver stains from the fingers and hands, and singularly enough, we have never heard of any serious injury arising from it. Still it is a procedure that is by no means to be recommended.

The fumes of the cyanide produce considerable inconvenience to some, while others are not in the least affected by them. A photographer we once knew could not use cyanide at all for this reason, and had therefore to fix always with hypo. So marked were the effects upon him that he could not remain for more than a few minutes in a dark room where it was being used without suffering from nausea and headache. In connection with the wet collodion process it may be mentioned that the acid iron developer had an unpleasant effect on the skin of some workers, making it hard and cracky. A photographer once, of our acquaintance, had to relinquish his business entirely on that account. The effect with him was chiefly on the palms of the hands; they were in a continual state of inflammation, and the skin cracked as the hands were used. But cases are rare when the sulphate of iron acts injuriously on anyone.

Again, the fumes of ammonia as they escape in the dark room, where pyro-ammonia is used as the developer, have an unpleasant effect on some, while they are quite inert with others. The usual effect is nasal catarrh. The best preventative is to have the room well ventilated and, as a palliative, plenty of outdoor exercise should be taken after the dark-room work of the day has been completed. While this is being taken, the breathing should be done through the nostrils as much as possible.

Platinum salts are found to affect some who use them continually, either in the platinum process proper or in toning silver prints, although it is quite possible that it is not the platinum salt, which, in every instance, is the cause of trouble. A case recently came under our notice of a platinum printer who was suffering from lung troubles which his medical adviser attributed largely to the fumes of the hydrochloric acid used for fixing the prints. It was alleged that this, if not the primary cause of the trouble, was a contributory one. He has now had to give up working the process. Again in a recent issue of "Wilson's Photographic Magazine," Mr. A. J. Jarman has a long article on "Platinum and Oxalate Poisoning." The early symptoms, as described by him, are a cracking of the skin on the backs of the fingers and slight pain when working with the solutions. Later on sores are formed on the backs of the fingers and pimples come on the wrists. The writer is here referring to the toning of silver prints with the phosphoric acid platinum bath, and he attributes the trouble more to the phosphoric acid than to the platinum salt, and, for this reason, recommends the employment of citric acid as the acid of the platinum toning bath. With regard to the injury arising from working the platinum printing process Mr. Jarman attributes the ill-effects to the corrosive action of the oxalate of potash developer, more especially when it is employed hot. Here, he says, the fingers become attacked at the base of the nails or between the nails and the flesh, often followed by festering. The writer of the article speaks of salivation being produced and the teeth loosened; this he puts down to the presence of mercury. We may here say that up to the present we have not heard of any authentic case in England of salivation arising from the use of sepia platinum paper, though we have of the other troubles described, but these, so far as we are aware, have only been experienced by those who work the platinum processes continuously, and on a commercial scale. In the case of amateurs and those who work platinum on a small scale there need be but little fear of suffering, particularly if the hands be thoroughly washed when the work is finished.

There are several other poisons that have to be referred to, and they will be dealt with later on.

ON THE DETERIORATION OF PLATES, PAPERS, AND FILMS.

A WARNING.

te, thanks to Messrs. C. Winthrop Somerville and R. E. Smith, the toning of bromide prints has become popular, especially with the formulæ worked out by the above-named man, which are exceedingly simple, and give tones of a pleasant and pleasing nature. In fact, there are many good reasons in favour of the sulphide bath. It is as well, however, to give a warning of the danger which lies in the fumes of sulphur which are given off from the sulphide of sodium bath. The evil is manifest when we note how the minute quantities of sulphur contained in one of our November fogs attack our articles in the house, producing a thin tarnish of sulphide of iron. We also know how easily these same articles are attacked when kept in a room where ordinary gas has been used as an illuminant, this being due to a small remnant of sulphur from the manufacture of the gas. How much more deleterious must be the large quantities given off from the sulphurising bath of sodium sulphide on the still more delicate bromide chloride of silver which go to make up the emulsions used on plates, papers, or films. Now, if these latter are kept in the same room where sulphide of sodium is employed, in a

few weeks these plates, papers, or films, as the case may be, will be unusable.

Take the plates first. These will develop with an iridescent stain, with general deterioration and fog.

Bromide and "gaslight" papers will also be affected in practically the same way, producing a dirty, flat, miserable print, so different from the first sheet one has used with so much pleasure before storing same where the sulphide bath has been constantly employed.

With P.O.P. the surface will assume a metallic lustre, and will be difficult to tone.

Naturally, a user of photographic material immediately jumps to the conclusion that the manufacturer is at fault, and that the plates, papers, or films are of poor quality, whereas sulphur is at the bottom of the whole matter, and the cause of the trouble is the sulphur fumes.

My advice to all who indulge in the toning of bromide or "gaslight" papers with the sulphide bath is to see that their papers, plates, and films are stored right away—in fact, in another room altogether—where no sulphur fumes from sulphur salts are liable to affect them. Such fumes act as a slow poison, but deadly in the end.

J. B. B. WELLINGTON.

MODERN CHEMISTRY FOR PHOTOGRAPHIC WORKERS.

V.—THE VELOCITY OF REACTIONS—i.e., CHEMICAL DYNAMICS.

may consider any chemical reaction from two points of view—either from the point of view of the final product reached, or from the point of view of the rate at which the reaction proceeds to form that final product.

In the fourth of these papers* dealt with the final statical result of reactions, and it is now desirable to consider the rate at which that result is attained. A chemical reaction proceeds in somewhat the same way as a ball thrown into the air, if one imagines that the ball, when thrown up, stays up and does not come down again; and one can consider the winding up of the ball either from the point of view of the height to which it attains or of the rate at which it attains that height.

In this paper for the first time we shall find it necessary to adopt mathematical methods, for this reason, that ideas of velocity, and rate of action, are essentially mathematical ideas. Attempting to get an idea of the course of a chemical reaction is met at once by a difficulty. This difficulty is found in the fact that as a general rule we can only form a theory for the progress of an infinitely small portion of a reaction, while we can only measure practically the effect of a very considerable portion. Consequently we have a great gap between our theory and our practical measurement. And this is bridged by casting our views of what happens in the infinitely small portion into the shape of an algebraical formula—which we call a differential equation—and we can then extend this to the whole time by the mathematical process of integration, which

gives us our original theory in a form in which we can verify it experimentally. We do not improve our theory by this process; we only make it possible to test it.

Velocity.

To give an example. Suppose we throw our ball into the air and wish to obtain a theory as to the rate at which it travels. We may suggest that at each second of its journey it travels somewhat slower than it did the last second, until presently it stops. It is difficult for us to measure the rate at which the ball does travel during each second, but if, taking our hypothesis, we add together the amounts by which the ball travels each second until it stops, and find the total, we can easily see whether this accords with the experimental result.

A velocity is defined as the amount of change taking place in unit time. If, for instance, a train travels a hundred miles in two hours, its velocity is fifty miles per hour. But this is the average velocity of the train; it is quite conceivable that the train might travel forty miles in the first hour and sixty in the second, in which case the velocity at any time would not be the average velocity for the whole distance.

Suppose, for instance, we drop a ball forty-eight feet, it will take two seconds to fall this distance, that is to say, it will travel with an average velocity of twenty-four feet per second. But as a matter of fact the velocity is increasing from beginning to end of the fall, starting with a velocity of 0 and ending with a velocity of forty-eight feet per second. So that we see that the instantaneous velocity at any time is quite a different thing from the average velocity. Now, velocity is measured

* "The British Journal of Photography," May 26, 1905.

in units of space divided by units of time, or, to put it algebraically,

$$V = \frac{s}{t},$$

and if we make our units of space very small and our units of time equally small, we shall get an instantaneous velocity. We write these very small units ds and dt , so that for an instantaneous velocity we get:—

$$V = \frac{ds}{dt}.$$

If we look at the subject graphically we may get a clear idea of what happens. On the curve we have traced the falling of a ball.

In the first second the ball falls... 16 ft. = 16 ft. from zero.

In the second second the ball falls 32 ft. = 48 ft. from zero.

In the third second the ball falls... 64 ft. = 112 ft. from zero.

In the fourth second the ball falls 128 ft. = 240 ft. from zero.

The average velocity for the first second is represented by line A; the average velocity for the first two seconds is represented by line B; the average velocity for the first three seconds is represented by line C; and the average velocity for the four seconds is represented by line D. But the instantaneous velocity of the ball at any time is represented by the slope of the curve itself, and this varies from start to finish. It can be found, as at E, by dividing a very small portion of space traversed by the correspondingly small portion of time taken to traverse it.

Velocity Constant.

Now let us turn to a chemical reaction. The simplest case of a chemical reaction is that of a substance in solution which splits directly up into something else. For instance, if we dissolve sugar in water which has been made slightly acid, the sugar will slowly turn into a mixture of glucose and levulose. In our fourth paper we saw that the mass law stated that the amount of reaction which proceeded in a given time was proportional to the mass of the reacting substances. Consequently we can see that the instantaneous velocity of the inversion (as this reaction is termed) of sugar will be proportional to the mass of the sugar which is not yet changed. That is, if m is the mass of the sugar to start with and x is the mass which has been changed, then $m-x$ will be the amount which has not been changed, so that

$$\frac{dx}{dt} = K(m-x),$$

where our $\frac{dx}{dt}$ is the instantaneous velocity.

This K is very important, because it fixes the rate at which the reaction progresses; it is called the velocity constant.

Integration.

In order to work with this equation it is necessary to change from an instantaneous velocity which cannot be measured to the amount of change which has taken place in a fixed time t , which can.

That is to say, it is necessary to add up all the values of $\frac{dx}{dt}$ from the beginning to the end of the reaction.

This is called integration. The mechanism is not simple; it really consists in a series of guesses until one fits, but the results can be given here. They are, for the integration of the equation

$$\frac{dx}{dt} = K(m-x)$$

that

$$K = \frac{1}{t} \log \frac{m}{m-x}.$$

The meaning of this is, that if we measure m , the total mass of substance at the beginning and then measure x at various times, and divide the value of $\log \frac{m}{m-x}$ by the time taken to reach x , we shall always get the same result.

For instance, the inversion of cane sugar was measured by Wilhelmy in 1850, and he gives the following results:—
 $m = 10.023$.

t	x	$K = \frac{1}{t} \log \frac{m}{m-x}$
0	0	—
30	1.001	.00152
60	1.946	.00156
90	2.770	.00156
130	3.726	.00155
180	4.676	.00151

so that we see K really is constant.

Orders of Chemical Reactions.

This is the simplest case of a chemical reaction. Chemical reactions are divided into two kinds—those taking place in systems in which only one kind of matter is present, homogeneous reactions as they are called, for instance, reactions

between gases or between substances in solution; and those taking place in systems where more than one kind of matter is present, for instance reactions between solutions and solids; these are called heterogeneous reactions.

Reactions are further divided into orders according to the number of molecules taking part in them. If only one molecule takes part they are said to be reactions of the first order, and the instantaneous velocity is proportional to the mass of unaltered substance, i.e.,

$$\frac{dx}{dt} = K(m-x)$$

If there are two molecules taking part, they are reactions of the second order, and the mass law shows us that the

ntaneous velocity will be proportional to the product of unaltered masses of both substances, i.e.,

$$\frac{dx}{dt} = K (m - x) (n - x)$$

e m and n are the initial masses of the substances. arly, we can have reactions of the third, fourth, and fifth s.

both the molecules are of the same kind in reactions e second order we get a very important case, which is attained if, in the case of two different molecules reacting, initial concentrations m and n are made equal. Then

$$\frac{dx}{dt} = K (m - x)^2$$

distinction between reactions of different orders is seen clearly in the fact that for a reaction of the first order velocity is simply proportional to the concentration for action of the second order to the square of the concentra- and so on.

Development a Heterogeneous Reaction.

e most important photographic reaction is, of course, rogeneous, that is to say, it is the reaction occurring een solid silver bromide and the developing ion. In this e we have already seen that we may imagine the silver ide to dissolve and dissociate, then reaction to occur een the silver ions and the developing ion. This reaction, g ionic, will, like nearly all ionic reactions, occur ntaneously, and then more silver bromide will dissolve and ociate.

we imagine the developer to be in such enormous excess e concentration does not appreciably change during loment (which is almost always the case in experimental

work), then the reaction which will fix the rate of development will be the solution of the silver bromide. Nernst and Wilder- mann have shown that we may consider that the rate of solution of a solid is proportional to the surface remaining, so that we may put for our instantaneous velocity

$$\frac{dx}{dt} = K (m - x)$$

where m is the original amount of "latent image" and x is the amount of developed silver at any time, t . It has been experimentally shown that the mass of the developed silver in a plate is proportional to the "density" (as defined by Hurter and Driffeld), while if we develop a plate until we can develop it no more we shall have in the density attained a measure of the "latent image" originally present. We may call this D_{∞} , the final density which we can possibly reach. And now our equation for the instantaneous velocity will be

$$\frac{dD}{dt} = K (D_{\infty} - D)$$

which is of the same form as the equation for a reaction of the first order, and on integration gives

$$K = \frac{1}{t} \log \frac{D_{\infty}}{D_{\infty} - D}$$

This has been experimentally verified.

In closing this series, a hope may be expressed that some of those who have followed it will desire to know more of these powerful physico-chemical methods of investigation, and, daring greatly, will recall sufficient of their earlier mathematics to follow some larger text-book on the subject. To such, the very excellent series of text-books of physical chemistry now being issued by Longmans and Co. are commended.

C. E. KENNETH MEES, B.Sc., F.C.S.

THE WEEK IN HISTORY.

The First Publication of the Calotype Process.

E 10, 1841, was the day on which Fox-Talbot described to Royal Society his calotype process, a patent for which he taken out on the previous February 8 ("The Week in ory," February 3). The description of the process and the ctions for working it are practically the same as those in patent specification. The points of novelty in the process chiefly:—The use of gallic acid or tincture of galls in con- ction with silver nitrate for producing paper of greater sen- siveness; the development of a latent image by washing the er with liquids affecting the light-affected parts; and the use otassium bromide as a fixing agent. Talbot also patented the lication of the method to the portraiture of persons. He impressed with the great rapidity of his paper. He says:— "the aperture of the object-lens is 1 in. and the focal length n., the author finds that one minute is amply sufficient in- ner to impress a strong image on the paper of any building n which the sun is shining."

Talbot's Daylight Development.

ox-Talbot's inventive genius led him, towards the close of his tographic work, to the method of developing plates in the era in full daylight. Many forms of apparatus for this pur- e have been invented and patented, and a good many of them e been more practical than the glass-cell which Talbot built e back of his camera. The back wall of the cell was of und glass, and on this Talbot focussed his picture. The plate e first sensitised in the cell with silver nitrate, and then osed, with allowance for the difference in its position and t of the focussing screen. Developer, water, and fixing solu- e were introduced in turn into the glass chamber, each being

drawn off after use by a cock. Talbot patented this and other devices on May 12, 1851.

Daguerre's Bargain with the French Government.

June 14, 1839, was a great day for Daguerre. On that date the French Chamber of Deputies passed the Bill by which life pensions were granted to himself and Isidore Niepce, the son of his deceased partner, in exchange for the publication of the great discovery. The facts which led to that event were, first, Daguerre's attempt in 1837 to float a company to work his process. A subscription-list was opened in that year, but the public did not respond. Then Daguerre sought the aid of Arago, the lead- ing French scientific man of the time, and himself a member of the Chamber. Through Arago the interest of the Minister of the Interior, M. Duchâtel, was gained, and the next phase was an agreement whereby M. Duchâtel was to ask the Chamber for annuities for Daguerre and his partner of 6,000 and 4,000 francs respectively in exchange for the process. The Bill was passed, and its terms make interesting reading. M. Duchâtel, who pre- sented it, dwells feelingly upon the importance of the new art which Daguerre and his colleague had called into existence. "M. Niepce," says the Bill, speaking of the dead Nicéphore, "in- vented a means of producing permanent images, but although he thus solved the difficult problem, his invention was very in- complete. He obtained only the outlines of objects, and re- quired twelve hours at least for the reproduction of the smallest drawing. In his researches M. Daguerre has followed entirely different methods from those adopted by M. Niepce, with what results we see to-day—viz., the extreme rapidity of the process and the reproduction of aerial perspective and the play of lights and shadows. The method is entirely his own, and is distin-

guished from that of his predecessor as much by the process itself as by the results obtained. However, the existence, before the death of Niepce, the father, of an agreement whereby he and Daguerre agreed to share with each other all the advantages accruing from their discoveries (and as this stipulation descends to M. Niepce's son) precludes us from dealing exclusively with M. Daguerre, even in relation to a process which he has not merely perfected, but has invented. . . . Thus it is clear why MM. Daguerre and Isidore Niepce appear to-day in the treaty which is appended to the Bill. The pension will be assigned thus:—

"6,000 francs to M. Daguerre.

"4,000 francs to M. Niepce.

"Apart from what has been said, there is another reason for this unequal division. M. Daguerre has consented to make known the methods by which he produces his diorama, an invention of which he alone knows the secret, and which it would be a misfortune to allow to be lost."

So Daguerre put his photographic discovery and the diorama

into one parcel and sold the lot for an annuity of about £250 per annum. And when, after a few months, he published a text-book on photography, he added a chapter on the methods of his unique invention, the diorama.

The Fixed-Focus Camera in 1850.

In some previous notes I have dated the era of the hand-camera from the model of Mr. Bolas, shown to the Royal Photographic Society twenty years ago. But the principles of the modern hand-camera are a good deal older than that. I can trace the "fixed-focus" method as far back as 1860, at any rate. On June 15 in that year M. Bertsch exhibited before the French Photographic Society a tiny hand-camera taking pictures only 6 by 4 cm., and he showed also enlargements from these small negatives 78 by 52 cm. The camera carried a lens of very small focal length. All the planes of the subject were sharply rendered without focussing, and, as M. Bertsch pointed out, the user needed no previous knowledge of photography.

HISTORICUS.

THE OPTICAL CONVENTION.

We give below three further papers read during the session of the Optical Convention which closed on Saturday last, June 3. That on "Stereoscopic Vision," by Mr. C. W. S. Crawley, is interesting as indicating the scientific applications of the stereoscopic method. Photographic stereoscopy has already been employed to advantage in the same domain, and no doubt much more will be done towards bringing about the much-talked-of "revival of the stereoscope," not, however, with that instrument in the rôle of popular educator and entertainer so much as in that of assistant in scientific measurements. The paper by Mr. W. Rosenhain draws attention to possible

directions of progress in the making of optical glass, and, although purely suggestive, may prove to have a bearing upon the aims of the photographic optician.

A paper by Lord Rayleigh, on the "Polishing of Glass Surfaces," is yet to appear, and we hope to print it in full in our next issue, in which, also, we shall endeavour to present the discussion arising out of the papers on aberrations by Mr. S. D. Chalmers and Dr. C. V. Drysdale, which appeared last week. These papers were largely suggestive and calculated to provoke discussion, and the full text of the views expressed should be a contribution to the subject even more valuable than the papers themselves.

STEREOSCOPIC VISION.

(A paper read before the Optical Convention on June 1, 1905.)

THE human eyes, faulty as they may be in many ways, are in one respect an instrument of extreme precision. As a means of instantly detecting minute differences of angle, they have a delicacy which is but seldom appreciated. Helmholtz has investigated the matter, and in his "Physiological Optics" describes experiments which show that the eyes are capable of detecting a difference between two angles of as little as one minute. This power of discrimination it is that enables us to judge distance by stereoscopic vision, not indeed to judge distance absolutely, but to say which of two objects is the nearer.

To take a concrete example. Let us place two rods or other suitable objects, the one at the distance of 2 metres and the other 2 centimetres further. Let them be nearly in the same line of sight, be perfectly evenly lighted, and have all surroundings cut off, so that there is no means of judging which is the further except the opinion that we form by looking at them. If we do so with one eye only, we could not say which was the nearer, nor could we even if they were much further apart.

With two eyes, however, no one with ordinary vision would have any doubt. One rod "looks" nearer than the other, though why it does we do not and cannot consciously realise.

This power of judging distance is common to all; it has always been advantageous to every member of the human race to judge distance, and to do so continually the whole time that he is awake. Evolution has consequently had its fullest opportunities, and has seized them with marvellous results.

How are we to judge that one of these rods is nearer than the other? Surely by the fact that when we look at it we have to converge our eyes a little more than when we look at the other.

The Delicacy of Human Stereoscopic Vision.

The proximate physical fact that we unconsciously judge by is an appreciation of the comparative muscular efforts to produce the convergence of the eyes on objects at different distances. Taking the eye distance as 65 mm., which is about the normal, the angle eye-rod-eye at 2 m. is roughly 1'57", while at 2 m. 20 cm. it is roughly 1'56". The difference of convergence of the eyes on the two rods is consequently only about 1 minute, and probably 98 per cent. of the population would have no hesitation about which is the nearer, and the remaining 2 per cent. would be found not to have stereoscopic vision at all. But with all reverence for a great name, Helmholtz put the limit far too high. From numerous tests in all sorts of conditions and ages of men and some women, as will be seen in Table I., we find that only in two cases was the angle even half a minute. The general angle appears to be about 10", and

really good men can appreciate with certainty a difference of 2 to 3 seconds.

TABLE I.

Tests at 7 ft. and 23 ft. 6 in. by two observers. Wax matches with red heads level with each other and with the eye. One match can be pulled towards or away on a slide, but nothing but the matches are visible. + means the movable match was set too far and *vice versa* - "0" means less than $\frac{1}{2}$ mm.

Distance 7 ft. 1 mm. = 2.3 sec.	Distance 23 ft. 6 in. 1 mm. = .28"

18 Res	50	19	81	Chemist.
19 C.P.	4	22	36	Board-school boy.
20 Hadl.	35	40	68	Engineer.

in repeating the experiments, there are one or two points that are to be attended to in order to ensure that the distance is judged only by stereoscopic faculty.

The lighting must be even and regular, and should be exactly the same as the observer, otherwise shadows may be of great help, and too good results unintentionally obtained.

The background should be fairly uniform, and preferably, at least, far off again as the rods. Ordinary wax matches make excellent backgrounds.

The holders, slides, and all surroundings must be cut off by a screen.

The eyes should be on a level with the tops of the matches. A great deal of most excellent work has been done on stereoscopic vision by Dr. Pulfrich, of Jena, and will be found in his various papers. Among other uses, he has applied it to surveying work, two photographs of the same landscape being taken, at a considerable distance apart, to increase the stereoscopic effect. (The Astronomer-royal at the Cape has also worked on this line.)

The Zeiss stereoscopic range-finder also is principally due to him.

The Stereoscopic Principle in Astronomy.

One of the most beautiful uses made of stereoscopic vision is in astronomical work, and is described in a paper by Dr. Pulfrich, read before the Astronomical Convention at Göttingen in 1902.

Photographs of the same region of the sky are taken at a suitable interval, which may be years apart, and viewed stereoscopically. The stars that have moved during the interval parallel to the line joining the eyes stand out in front of the plane of the others, or retire behind that plane, and are spotted instantly and with certainty. This is the very first stereoscopic effect that we can ever hope to see. If we take two photographs at a year's interval in a direction at right angles to the line of the sun's motion in space, that motion being about 35,000,000 miles per year, when we put the two in a stereoscope we get the effect of a stereoscopic base of about 35,000,000 miles, and as photographs are now taken continually, we will steadily enlarge that base year by year, and century by century.

Stereoscopic Radiography.

Dr. McKenzia Davidson has used stereoscopic vision for X-ray work. An X-ray photograph of a leg, for example, is taken; the tube shifted a few cm. to one side, and another photograph taken. When the two photographs are viewed in a stereoscope, instead of having a flat diagram, all the bones stand out in perspective, and any foreign bodies, such as bullets, needles, etc., can be exactly localised. This has gone further. Two tubes, a little distance apart, are worked alternately. A vibrating shutter in front of the right eye is opened when the left tube is closed, and vice versa. A perfect stereoscopic effect is thus obtained. Incidentally the two photographs need not be equal; one may be so bad as to give an extremely weak picture, and yet the stereoscopic effect will be perfect.

In the same way a man may have one eye very defective indeed, and yet have good stereoscopic vision.

The Range Finder.

It was mentioned above that an exceptionally good man will appreciate as little as 2 to 3 secs. Of course, when working with rods as described there is a feeling that the readings may have been assisted by shadows, or in some way unconsciously "cooked." The figure, however, confirmed by tests with the Forbes' Range-Finder. Now in this case no such chance of error can arise, as there is no question of judging by anything but stereoscopic vision, pure and simple.

The instrument is fairly well known, but a few words of description may be given.

The object is viewed through a prismatic binocular. In the focal plane of the object-glasses of the two sides are two absolutely similar photographs of a balloon on clear glass. The two appear one by stereoscopic vision. If they are both at the centre of the field they appear at the same distance as an object at

practically infinite distance, say, the moon. One of them can be brought towards the other by a micrometer screw, and the eyes must converge a little to still see them as one object. The balloon then appears at the same distance as an object on the landscape, on which the eyes have to converge at the same angle. By moving the screw the balloon can be made to appear to approach or recede till it appears the same distance as any particular object; the range of the latter is then shown on the perfectly divided screw-head. With the ordinary binocular of eight magnifying power, and about 3-in. eye-distance, the range that can be taken to one or two per cent. is limited to about 120 yds., but by adding an arrangement of prisms on a base 6 ft. long, the same effect is produced as if the eyes were 6 ft. apart, and distances twenty-four times greater—say 3,000 yds.—can be taken.

The pointer on the scale can be set autonomously, if one may be allowed the expression, i.e., without reference to any known distance. A reading is taken of any object at suitable but unknown distance, first with the binoculars alone, then with the base added. From these two readings an accurate setting of the pointer can be made.

Very numerous trials have been made with this instrument, both in the Army and Navy and with civilians. The sailor might have been expected to have come out far better than the soldier, owing to his having to exercise his sight more, but there is no noticed difference. The common private in the Army can almost always after half an hour's instruction—often indeed after only five minutes—take a range of about 2,000 yds. accurate to 20 yds. This with a 6 ft. base and eight magnification power is equivalent to 17 ins., and in a very few hours he will be taking 3,000 yds. accurate to about 30 yds.

As might be expected, some men are better than others. One or two skilled Army sergeants give very good results, but this may in some cases be due to other marked causes—general smartness—rather than really better stereoscopic power. But there is one observer we have come across who has distinctly greater stereoscopic power than the average. The first time he saw the instrument was at Bisley. He then looked through it at a target distant some 1,140 yds. and ranged it within 2 yds. first shot. There are two of his readings that may be mentioned. A tower of Holloway College at Egham was just visible among the trees on the sky line. It was a nasty object—that is, its surroundings made the stereoscopic effect difficult to get. Five readings of this were taken, and the middle one of them—which has always been found far more reliable than the mean—gave the distance, 10,740 yds. as measured in the Ordnance Map, correct to 100 yds. in 10,000. This gives 7 ins. on a bad object at very long range indeed. Another case was at Gibraltar—same observer. His readings on the corner of a castle were 2,147, 2,149, 2,149, 2,147, 2,147, 2,145.

Here then we have five successive readings, the maximum difference being 4 yds., which, with eight magnifying power at 2,000 yds., means an angle of 2.8 secs. as maximum error. His note on this says:—"The scale of instrument at this range does not permit of accurate reading to less than 5 yds., but knowing that the greatest possible precision was wanted I estimated the values of very slight differences in a set of almost identical readings. I might have entered them all as identical except the last."

When he had finished he was told by the R. E. Captain before whom he was working that the distance was 2,451 yds. He thereupon checked his Range-finder autonomously, found it perfect, and asked to have the R. E. measurements checked, as they were certainly wrong. They were re-checked, and the actual distance was found to be 2,145.7 yds.

Light, atmosphere, and object were no doubt perfect; but that merely means that there were no opposing elements, not that there was any assistance from any other source. The distance was measured repeatedly and accurately by the stereoscopic power, and that alone; that reduces Helmholtz's 1 minute to about 3 seconds.

C. W. S. CRAWLEY.

THE PRINCIPLES OF TRICHROMATIC PHOTOGRAPHY.

(A paper read before the Optical Convention on June 2.)

The most successful processes, up to the present, of photographically reproducing the colours of objects are those founded primarily upon the fact that all common colours can be imitated by mixtures of the three primary colours, red, green, and blue.

Processes of this class readily fall into two groups—those in which a final picture is produced by the addition of the primary colours in projection, as in Ives' Kromskop (positive synthesis), and those where the primary colours are absorbed by the pigments used for printing, such as Lumière's transparency process and typographic colour-printing (negative synthesis). This latter is the only aspect of the subject which has assumed much commercial importance.

Colour-mixture Curves and the Reproduction of the Spectrum.

The idea of reproducing the spectrum by a photographic process

founded on Maxwell's colour-mixture curves is a simple one. The ordinates of these curves give for every part of the spectrum the proportions of the three primary colours necessary to give the closest match to the hue. If three photographic negatives of a spectrum of white light could be obtained whose opacities correspond exactly to these curves, and if from these, transparencies (positives) were made in which the transparency followed the same curves, and then images of these projected on a screen in their proper positions and illuminated each by its own particular primary light, then Maxwell's operation of matching each part of the spectrum by mixtures of red, green, and blue lights would have been accomplished photographically, and the reproduction would be perfect except for a slight degradation with the sensation of white in the yellow and blue-green regions and the loss of the violet if the pure blue had been taken as one of the primaries.

Theories of Colour Photography.

Before entering into detail regarding conditions imposed by the nature of ordinary colours and the properties of photographic plates, it may be well to review some of the numerous hypotheses that have been advanced upon this subject, of which naturally not more than one can be correct, bearing in mind that the usual problem is not necessarily to reproduce all monochromatic hues, but the colours which are commonly met with in Nature.

The principal hypotheses may be grouped under five headings:—
1. *Colour-Sensation Curves.*—These have been made the foundation of a few hypotheses. According to one authority, the densities of the negatives of a spectrum should follow these curves,¹ or the colours photographed should be those most representative of the primary sensations.² This latter would seem to indicate that they should be somewhat narrow bands.

Dr. Clay, taking Sir William Abney's colour-sensation curves as a basis, has worked out the curves that should be followed by the negative records in reproducing the spectrum in order that the degradation of the colours should be with the sensation of white only. In this connection he points out that inks with abrupt absorptions give rise to purer sensations than those with gradual absorptions.

2. *Colour-Mixture Curves.*—Mr. F. E. Ives, one of the pioneers of three-colour work, is the chief exponent of the idea that the density of the negative records should follow the colour-mixture curves,³ Von Hübl admitting the possibility of the hypothesis being correct. Mr. Ives' specification of the printing colours is that they should be those most anti-chromatic to the colours photographed, and evidently intends that the absorptions should be gradual.

Many writers have unfortunately written upon this subject, and confused the sensation and mixture curves, although the functions represented are totally distinct.

3. *Negative Records Derived from the Ink Absorptions.*—The method of adjusting filters and plates put forward by Von Hübl consists in determining the "middle absorptions" of the printing colours and calculating curves for the negative records, whose maxima are in the same positions as these absorptions, and which terminate at the adjacent "middle absorptions." It is, however, interesting to note that he appears to make but little attempt to carry this idea out in practice, relying rather upon the indications given by a colour chart.

4. *Equal Division of Spectrum.*—Both Dr. Adolf Miethe and Mr. Howard Farmer consider that the filters should divide the spectrum into three parts without any overlapping at about λ 6,000 and λ 5,000, although in one of his papers Dr. Miethe describes a method of introducing an artificial overlap effect by giving short supplemental exposures through the other filters.

5. *Regulated Overlap.*—Two considerations, firstly that photographic action does not follow a straight line law, and secondly, that filter records following extended curves would reproduce certain colours with the addition of actual white or the adjacent spectrum colours, have led the author, in conjunction with Messrs. A. C. Jolley and A. J. Newton, to develop this hypothesis, and to follow it out in practice.

In this method of working, negative records of a normal spectrum are made as even, and to terminate as abruptly, as possible. The region of the spectrum in which the red and green records overlap is reproduced by the printing colour of the blue negative, a yellow. Similarly the part photographed by both the green and blue negatives is rendered by the blue-green pigment used in printing from the red negative.

In any photographic process the ink, etc., is printed from the parts which are transparent in the negative, i.e., where the light has not been recorded, so that in printing in pigments these should absorb all the light photographed by the negative from which they are printed and be transparent to the light not so recorded. This gives the following inter-relation between the negatives and printing colours:—That the sum of the colours of the region of overlap between the red and green negatives should accord as nearly as possible in hue with the sum of the colours not recorded by the blue negative, and also that the colours not recorded by the red negative should match those in the overlapping region of the blue and green negatives. These regions have been selected and matched visually,⁵ but owing to the fact that in each case the colours having the more extended composition stimulate the third sensation more than do the colours of the overlapping regions, and also because these latter regions occur in those parts of the spectrum where the hue changes most rapidly, and is not always seen in exactly the same manner by different eyes, the matches cannot be made with any great degree of accuracy. It is, however, interesting to note that filters and plates

adjusted on these principles have given under comparative test superior results to all other obtainable filters (twelve in number).⁶

So far as work along these lines has gone, it shows that the three negative records should, as far as is possible, extend evenly between λ 7,000 and λ 5,800, λ 6,000 and λ 4,600, and λ 5,000 and λ 4,000, the corresponding printing colours absorbing these regions and transmitting the remainders.

This system of three-colour reproduction tends in practice to render the varying hues of the spectrum by five patches of uniform colour.

Some Consideration of Negative Records Intended to Follow Curves.

The adjustment of a light-absorbing medium to correct the sensitiveness of any photographic plate so that the effect should follow some premeditated curve is a matter of great difficulty—so great that, in spite of several claims that have been put forward, it is a matter of great improbability that anything in this direction has even been accomplished, the few filters of this type which the author has examined not being very successful.

Suppose, for instance, that a record was required with a maximum in the orange at λ 6,100, the curve sloping in some particular manner down to the end of the red on one side and to some point in the green on the other. Now, as far as gelatine plates are concerned, the sensitiveness of even the best panchromatic ones is extremely low to the region λ 7,000 to λ 6,300, in but few of them can the record be pushed beyond λ 6,500, unless they are screened from the action of the shorter wave-lengths and given greatly prolonged exposures; so that it would be practically impossible to effect the adjustment required. Again, the various bands of comparative insensitiveness that occur in the green and blue-green with the best modern sensitizers would greatly increase the difficulty of making adjustments to curves in this region.

But if the adjustments were possible, the curve effect required could only be obtained when exposing to the spectrum at some one critical exposure and developing to a particular development factor, for since photographic action does not follow a straight-line law, any increase or decrease in the exposure will cause an alteration in the shape of the curve, the densities of the various parts not increasing or decreasing in the same ratios. Now an ordinary negative consists of a photographic plate which has received various exposures according to the light and shade of the original; such a filter and plate would therefore be acting in a different manner in different parts of the same negative. Variations of this nature can be followed by giving various exposures to a spectrum, in proportion to the variation of light and shade in any picture. These variations have been found to be considerable in some cases.

It is for this reason that test-charts of light colours, such as those published by Von Hübl and by Eder, are of limited utility, since while they may be well rendered, a picture with greater contrast of light and shade photographed on the same negatives may be so indifferently reproduced as to be almost useless.

Relation of Ordinary Colours and Monochromatic Colours as Regards their Reproduction.

It does not of necessity follow that if a set of filters and plates could be made to reproduce a spectrum of pure colours exactly that it would render ordinary colours well, although this point is often assumed as being self-evident.

To render a spectrum correctly by positive synthesis the negatives must follow the colour-mixture curves. Negative synthesis would require either these same curves or some derived directly from them (probably the former), but the ordinary colours of objects would, because of their complex composition, be rendered too light in many cases. A red colour, for instance, which reflects light of the red end of the spectrum up to perhaps λ 6,000, would be photographically recorded to some extent by the green negative as well as the red, instead of by the red only. So that in the reproduction insufficient crimson would be printed on the yellow, resulting in too orange a hue.

An orange colour reflecting the red, yellow, and part of the green of the spectrum might be well rendered, but a yellow which reflects all the light between λ 7,000 and λ 5,000 would be rendered much lighter because of its being recorded in the blue negative. The case in which this effect would be the most marked would be that of a green colour.

Fundamental Requirements of the Reproduction of Colours.

It is necessary, quite apart from their relations to the negatives, that the colours employed in building up the final pictures shall themselves be capable of reproducing all ordinary colours by suitable mixture or super-position. For positive synthesis they must be the primary colours—red, green, and blue, or blue-violet; but they need not consist of monochromatic lights only. Fairly broad bands of the spectrum may be taken provided that they are not more impure than any colours likely to occur in practice. Negative synthesis requires that the primary colours may be produced by superposing the printing colours in pairs—that is to say, the yellow and crimson should give a red as pure as any that are ordinarily met with, which means

⁶ "The Practical Performance of Tri-colour Filters," by A. J. Newton and A. J. Bull (*Photographic Journal*), October, 1904.

that these two colours between them must absorb the spectrum yellow, green, blue, and violet, leaving the red and orange-red only. Similarly the superposition of the yellow and blue-green must effect the absorption of all parts of the spectrum not sensibly green in hue, i.e., the spectrum red, yellow, blue-green, blue, and violet, and the crimson and blue-green must together absorb the red, yellow, green, and blue-green. This indicates that the crimson to be used should absorb the yellow, green, and blue-green; the yellow should absorb the blue-green, blue, and violet; and the blue-green the red and yellow of the spectrum. This corresponds with the properties of the printing colours as indicated by the method of regulated overlap.

Among the defects that occur in the reproduction colours for negative synthesis the most serious are in the blue-green, where there is generally a want of transparency to the green and an incomplete absorption of the red. These cause a darkening of the greens and a difficulty in obtaining blacks and greys free from a red tint.

The crimson is seldom as transparent to the blue and violet as it is to red, so that when superposed on the blue-green it produces a purple instead of a blue-violet, also as the spectrum yellow is often transmitted, the red given in conjunction with the yellow is too orange in hue. There is no difficulty in obtaining a suitable yellow.

In the staining of gelatine reliefs, fast green B.S., erythrosin, and brilliant yellow are very good dyes to use.

Inks for block-printing are generally much inferior in their properties to the dyes for making transparencies. In many cases the makers put forward inks which not only possess the defects mentioned in a most marked degree, but also the yellow is too pale, reflecting more blue than is necessary, and making the hue obtained by printing the blue ink on it a blue-green instead of green. Under these circumstances greens and yellow-greens are only produced by additional fine etching. Another serious defect with tri-chromatic inks is that they are never sufficiently transparent, so that they have

to be printed in the order of their opacities, which is usually yellow, crimson, blue.

The Mutual Adjustment of Filter Records and Reproduction Colours.

The adjustment of the filters to the inks, or the selection of suitable inks for certain filters, is often considered essential. The adjustment usually consists in making the filters reproduce the inks—that is, each filter and plate must record two of the inks equally while not photographing the third.

With the red negative there is no difficulty in recording the red and yellow inks equally, but in order to make the blue-green ink photograph equally with the yellow, the green record must be extended into the blue considerably, with a consequent loss of green. The effect of this is prejudicial to the reproduction of greens, as the whites are recorded with greater densities in the negative than any bright greens, so that more crimson is printed on the greens than on the whites.

The blue negative, if it records the visible blue and violet only, will photograph the blue ink more than the crimson, because of the deficiency of blue in the latter. But as most of the crimson inks in use reflect more ultra-violet than violet, the records of these two inks may be approximately equalised by recording the violet and ultra-violet rather than visible light only. This adjustment produces its own defects on certain colours. Many reds, browns, and oranges, for example, reflect some ultra-violet, and this being recorded in the blue negative prevents sufficient yellow being used in their reproduction, thereby giving them a violet tint. Blue colours, too, may also be affected. So that, if the filters and plates are adjusted to copy the inks when these are defective, incorrect effects will be introduced in the rendering of colours which differ from them. The better plan is to adjust the filters and plates to approximate as closely as possible to theoretical requirements, and to independently follow the same course with the reproduction colours.

A. J. BULL.

POSSIBLE DIRECTIONS OF PROGRESS IN OPTICAL GLASS.

(A paper read before the Optical Convention on June 3.)

THE epoch-making work of Schott and Abbe, and its developments at the Jena works, have made and are still making their mark in every field of optics; but while fully valuing this work and the results which have flowed from it, the writer is inclined to deplore one consequence to which it seems to have led—namely, a species of contentment with results already achieved, and a concomitant slackening of the demand for further advance. The progress in optical glass during the past twenty-five years has not, in all probability, exhausted the possibilities of homogeneous transparent media which might be made available to the optician. Quite recently we have witnessed the introduction of microscope lenses made of fused silica, and of glasses made particularly transparent to ultra-violet light, while the use of the natural mineral fluorite in certain microscope objectives illustrates the fact that the glass-maker has not as yet met all the desiderata of the optician. The probability is, however, that in this field all the easier tasks have been accomplished, and that thus the fairly obvious commercial possibilities of optical glass have been exploited. If this be so, further progress must depend upon investigations made for scientific purposes and not undertaken commercially. It is, of course, more than likely that commercial success might ultimately reward an investigation of that kind, but the probabilities of such an issue are not sufficiently clear to encourage anyone to embark on such a task on purely business principles. It is interesting to recall the fact that the great development of optical glass, which has originated at Jena, began as a purely scientific research, rendered possible by the timely financial aid of the Prussian Government. It is perhaps permissible to express the hope that if on fuller consideration the investigations outlined in the present paper are found sufficiently promising to be put into practice, this forward step may not be left to be taken by workers in other countries.

Media other than Glass.

Leaving aside for the time all questions of ways and means, the present paper is intended to point out some possible directions in which transparent media, widely different from optical glasses as now available, might be sought. For obvious reasons, the author proposes to deal with the question rather from the physico-chemical standpoint of the modes of production of such media than from the point of view of their most useful application; he is, however, sufficiently acquainted with the requirements of opticians to be aware that a wide extension of the available range of optical materials would be warmly welcomed, and would be likely to lead to great advances in optical systems. It should perhaps be explained that the term "transparent media" has been designedly used in preference to the more familiar word "glass," because the author believes that, at all events in certain cases, the substances in question can only be obtained in the crystalline state, to which the term "glass" cannot be legitimately applied.

Conditions of Glass-making.

On looking at the lists of optical glasses now available, one is struck by the fact that the limits between which the chief optical

constants vary throughout the entire range of glasses are distinctly narrow. The refractive index always lies between 1.46 and 1.90 while the constant generally designated by the symbol ν varies from 67 to 29, and in estimating this range glasses are included which are not well suited to most practical uses. The question naturally arises whether these limits are purely accidental or whether there is some physical fact at their basis. In favour of the latter view considerable evidence is to be found, principally in the nature and behaviour of the glasses which form the extreme members of the existing series, and particularly of those in which the relation of dispersion to refraction is abnormal, i.e., in which a high refractive index is combined with a low dispersion. In order to appreciate this evidence, and also with a view to leading up to ideas required in a later part of the present paper, it will be desirable to briefly consider the physico-chemical conditions governing the production of a glass.

In the fused state a glass may be regarded as a homogeneous solution of a number of chemical compounds; in solidifying when cooling, such a solution may behave, so far as the final result is concerned, in either of two ways: in one case solidification begins sharply at some definite temperature dependent only on the chemical composition of the mass, and the absolute pressure, and the resulting solid mass, when cooling has been carried far enough for complete solidification, forms an aggregate of crystals; in the other case, cooling continues without the occurrence of a definite change at any definite temperature, the liquid gradually becomes more and more viscous, until at a sufficiently low temperature the viscosity is so great that the mass has most of the properties of a solid, and crystallisation is permanently inhibited. It is probably a sound generalisation to say that, under suitable conditions, any fluid could be made to undergo either of these processes, i.e., could be caused to solidify in the vitreous, amorphous state, or in the crystalline state.¹

The conditions which govern the mode of solidification resulting in any particular case vary considerably with the chemical nature of the substances in question; as in our ordinary laboratory and industrial operations the rates of cooling do not vary very widely, it is ordinarily stated that some substances, such as silicates, naturally assume the vitreous state, while metals habitually assume the crystalline state; but—theoretically, at all events—this is merely a question of the rate of cooling and of the absolute pressure. As a matter of fact, in the case of 153 substances chosen at random by Tammann, 59 could be obtained in the vitreous state, while only 22 could not be seriously undercooled; on the other hand, every known vitreous substance, with the exception of boric anhydride, can be caused to crystallise by suitable treatment.

Artificial Conditions of Cooling.

Taking, then, the conclusion that glasses are simply greatly undercooled liquids produced by a rate of cooling sufficiently rapid to

¹ For some of the facts and many of the theoretical deductions contained in this section the author is indebted to Prof. G. Tammann, whose book, "Kristallisieren und Schmelzen" (Barth, Leipzig 1903), is an exhaustive treatise on these questions.

prevent crystallisation from setting in during the passage through the critical range of temperature, the behaviour of extreme glasses in this respect may be considered. It is a statement amply justified by experience, that when the chemical composition of a glass flux is altered with a view to obtaining extreme optical properties, the tendency towards crystallisation increases rapidly. Up to a certain point this can be and is overcome by accelerating the cooling of the glass, but it cannot be carried further without breaking the mass down into useless fragments, and this forms one of the limits to the range of optical glasses in several directions. Possible means of overcoming this difficulty is, indeed, suggested by one of Tammann's conclusions. He has shown that, for certain chemically homogeneous bodies the melting-point is raised by raising the absolute pressure, ultimately reaching a maximum value. It follows that a more rapid passage through the critical range would be possible when the position of that range on the temperature scale was considerably raised. Consequently glasses which show too great a tendency to crystallise under ordinary conditions might be retained in the vitreous state by cooling rapidly under pressure. The pressures required are, however, enormous, and under existing conditions the application of this interesting theoretical conclusion to practice does not seem possible.

Chemical Limits to Variations in Optical Glass.

Returning to the natural limitations in the production of optical glass, it is a further fact of some importance that all extreme glasses are of the nature of very active chemical agents, both in the fused state and in the ordinary solid condition. The latter fact has eliminated from practice a large number of glasses of most desirable optical properties, as they proved entirely unstable in contact with the atmosphere; while the former condition imposes a limit on the production of such glasses on account of the destruction of the vessels in which the glass is melted. It is, however, a curious fact that the tendency of such extreme glasses in the fused state is to take up from surrounding bodies such substances as will tend to change the optical properties of the glass *towards*, and not away from, the "normal" condition.

The conclusion to which the author is thus inclined to come is that the range of optical glasses is limited by physical and chemical conditions which are intimately connected with the optical effects of the glasses, the most serious of these limiting causes being the tendency to crystallisation. On Drude's electro-magnetic theory of refraction and dispersion, the optical constants of a glass depend upon the position of its absorption bands in the ultra-violet or the infra-red region of the spectrum, and it is possible that the constitution of molecules, or groupings of molecules, requisite to effect the absorptions correlated to "abnormal" optical constants, is such as cannot readily exist without the additional support or stability derived from crystalline arrangements.

Crystallisation—the Direction of Experiment.

From the considerations here advanced, the author is inclined to draw the conclusion that any considerable extension of the range of available optical glasses is not likely to be made on lines at all analogous to those pursued in the production of glasses. The most promising direction of progress is to be found, in his opinion, by accepting the limitations discussed above, and in fact taking the line of advance indicated by the most serious of those limitations, viz., the tendency to crystallisation. The object to be aimed at, then, becomes the production of crystals of composition and properties suitable for optical uses. It must, of course, be admitted at the outset that the task is an exceedingly difficult one, but probably not more so than the problem of the production of homogeneous optical glass in large masses must have appeared to the men who attacked that problem a century ago. Before, however, dealing with some of these difficulties in detail, it will be well to consider some of the definitely known factors of the question.

In those cases which have so far been measured, a considerable difference has always been found in the optical behaviour of the same chemical substance in the vitreous and the crystalline condition. This is well known in the case of silica, and in the case of several experimental glasses produced by the author, of chemical composition identical with that of certain minerals, the same fact was met with, but to a still more marked degree. In these latter cases, the optical behaviour of the crystalline mineral was very "abnormal," and here again the change produced by the conversion into the vitreous state was in the direction of more normal optical properties. The author has also studied the crystals formed during the slow cooling of some optical glasses of extreme properties, and so far as microscopic methods would permit of their determination, these crystals also differed widely in optical behaviour from the glass in which they had been formed. These facts are referred to here because the author wishes to emphasise the fact that he is not advocating the attempt to produce novel glasses by the imitation of the composition of minerals of promising optical properties, nor yet the attempt to obtain in optically

useful form the crystallisation resulting from the "devitrification" of extreme optical glasses, as he does not regard either of these processes as particularly promising. The course that is most likely to lead to valuable results is arrived at from considerations of the conditions to be fulfilled by a crystalline material that is to be used for optical purposes.

Practical Requirements for Crystalline Refractive Media.

The first of these conditions is, of course, transparency, and the exclusion of all colouring oxides thus becomes imperative; the great majority of natural minerals are ruled out by this condition. The condition of perfect transparency also demands that individual crystals of sufficient size can alone be used, crystalline aggregates being useless; for anything beyond the smaller microscope lenses, therefore, the production of large and perfect artificial crystals would be essential. Also, where the optical system is intended for the transmission of rays at a considerable angle to the axis, double refraction in crystals would be a fatal objection, and this condition restricts the available materials to those which crystallise in the regular system. Finally, the optical properties of the artificial crystals sought must be of special value to the optician.

Guides to Experiment.

The only possible preliminary guidance in the study of this question is to be derived from a knowledge of the optical properties of natural crystals of the regular system. Unfortunately, the optical properties of most of these have only been studied hitherto with a view to their identification by the mineralogist. A preliminary to the course of investigation here suggested would therefore consist in the detailed investigation of the optical properties of natural minerals, from the optician's point of view, and for a reason to be presently given, the coloured minerals should not be excluded from this study. Even this preliminary investigation is beset with difficulties, owing to the fact that many mineral varieties could only be obtained in very small pieces. Modern optical appliances should, however, overcome this difficulty. As a preliminary indication of the range of optical properties likely to be met with, the following table of refractive indices of minerals crystallising in the regular system is given, being taken from Rosenbusch's "Hilfstabellen zur Mineralbestimmung."

TABLE OF NATURAL MINERALS CRYSTALLISING IN THE REGULAR SYSTEM.

Name of Mineral.	Optical Properties.		Empirical Chemical Formula.
	n_D	v	
Opal	1.45	...	$\text{SiO}_2 + i q$
Spinel—			
Spinel	1.715	...	MgAl_2O_4
Hercynite	1.749	...	FeAl_2O_4
Gahnite	1.765	...	ZnAl_2O_4
Chromite	2.096	...	FeCr_2O_4
Fluorite	1.4388	95.4	CaF_2
Garnets	1.747 to	...	(Ca, Fe, Mn, Mg)
	1.812	...	(Al, Fe, Cr, Si, O) ₁₂
Leucite	1.508	...	(K, Na, Al, Si, O) ₁₂
Sodalite	1.484	...	(Al, Fe, Cr, Si, O) ₁₂ + NaCl
Hauyn	1.496	...	2(Ca, Al, Si, O) ₁₂
Zeolite	1.483	...	Na, Al, Si, O ₁₂ + 2Aq
Perowskite	2.38	...	CaTiO_3

(From H. Rosenbusch, *Hilfstabellen zur Mikroskopischen Mineralbestimmung in Gesteinen*, Stuttgart, E. Koch, 1888.)

It will be seen from this table that a very considerable extension of optical properties would be made available by the artificial production of these minerals in an optically useful form, but it must be remembered that the minerals shown in this list do not represent the available extremes, as a large number of crystalline bodies are known in the laboratory of the inorganic chemist whose properties of hardness and permanence would fully equal those of the natural species, while their artificial production would probably present no greater difficulty. Further, our knowledge of the nature of crystals enables one to foresee that in all probability a very great range of intermediate species, and even of more extreme varieties, might be produced, principally by two well-known methods of changing the properties of crystals—viz., by the substitution of one chemical element for another of the same group, either wholly or in part, and by the production of mixed crystals or solid solutions. In connection with the former mode of procedure, it would be interesting, for example, to obtain a fluorite in which the calcium had been replaced by magnesium, or by strontium or barium, substitutions which would in all probability be readily effected once the method of artificially producing fluorite crystals had been mastered. Colourless analogues of coloured minerals might also be obtained in this way.

Mechanism of Artificial Crystallisation.

With these indications of the possibilities of the field, it remains to consider what is our existing knowledge of the artificial production of mineral crystals, and especially of large crystals. It is, of course, well known that a great number of natural minerals have been produced artificially, but so far as the author is aware, considerable gaps remain to be filled up; that these minerals have as yet been produced in large crystals is also well known elsewhere the world would long have been flooded with artificial precious stones. On the other hand, recent advances in physical chemistry have greatly extended our knowledge of the mode of formation of crystals, and have elucidated some of the conditions which govern their rate of growth and the size attained. In a general way, it has long been known that gradual solidification, either in the molten or dissolved state, is favourable to the formation of large crystals, but the work of Tammann has thrown further light on this subject. He has studied the formation of centres of crystallisation in variously undercooled liquids, by exposing the liquid in question to a certain degree of under-cooling for a fixed time. A certain number of centres of crystallisation are formed under these conditions, but if the under-cooling is sufficient to remain entirely invisible for a very long time, as, owing to the diminution of the rate of crystalline growth with fall of temperature, the rate of crystallisation is too slow; this rate is, however, readily accelerated by raising the liquid to a temperature below its normal freezing point, and the previously invisible centres of crystallisation are then developed into small crystals, which may be counted. This process is interesting in the present connection because it suggests a means, in certain cases, of regulating the number of centres of crystallisation formed in a given mass of liquid by suitably timing its exposure to a low temperature; only a very few such centres be allowed to form, and the liquid reheated to a suitable temperature and maintained there.

comparatively rapid crystallisation might be allowed to take place compatibly with the production of large individuals. It should perhaps be recalled in this connection that the matrices from which crystallisation takes place are frequently solid, and that, no doubt, the above order of ideas is equally applicable to these. Perhaps the most important inference in the present connection from these results of modern physico-chemical research is that extremely slow cooling through very wide ranges of temperature is not, in many cases, essential to the production of large crystals, but that the rate of passing through certain easily ascertained critical temperatures is the governing condition; this renders the whole problem much more hopeful of practical solution, since modern electrical methods render the accurate measurement and control of high temperatures possible. The natural process of mineral formation has no doubt, as a rule, involved extremely slow cooling through the entire range, but it seems that for practical purposes it will only be necessary to imitate a very small part of this process, so that hours instead of centuries may suffice.

Another large class of crystalline bodies is formed without the intervention of fusion, and the mode of production of large crystals from aqueous solutions is already well known where their production depends on deposition from ordinary solution. Further possibilities are presented by the gradual formation of crystalline substances insoluble in the liquid present, by gradual chemical action between dissolved bodies. Crystalline bodies may also be formed by deposition from the gaseous state, and the influence of temperature, pressure, and ionisation on these actions remains to be studied.

The object of the present paper being rather to indicate the possibilities of progress, it would not be profitable to pursue these questions any farther. The author believes, however, that enough has been said to show that in the study of the nature and mode of production of large mineral crystals may well lie the key to further progress in optical materials.

WALTER ROSENHAIN, B.A.

REMINISCENCES OF THE DUBLIN CONVENTION OF 1894.

As often been asked which might be considered the most successful Convention held since the movement or gathering was first inaugurated in 1886? Well, as Dogberry observes, "comparisons are odious," and it might seem invidious to single out one particular meeting. The majority have been good; several have been very enjoyable without leaving any particular mark on the memory; but among those standing out in bold relief must certainly be included the Dublin Convention of 1894.

Those who were present have alluded to it scores of times, and they are undoubtedly looking forward with pleasant anticipation to the meeting which will take place in Ireland from the 10th to the 15th of next month.

"Dear, Dirty Dublin."

Ireland is unlike any other place that I am acquainted with, the people are unlike any other people; and a very beautiful country and a very charming people they are. "Dear, dirty Dublin," has many attractions, and even the three hours' sea passage which divides us from it is a most enjoyable time to many.

Of course, the St. George's Channel is a little breezy at times; but the English Channel; so are several other Channels; but good weather should prevail in July, and the Convention meetings in that month have been very fortunate in this respect.

In recounting a few reminiscences of the 1894 meeting it will perhaps be better to begin at the commencement, and take them in order.

En Route.

Common with many others bound Dublinwards, I started on the evening, and nothing very remarkable occurred until the train arrived at Chester. Here we heard a well-known voice inquiring if the train went to Ireland. We opened the door and let him in. It was accompanied by a stereo camera, and the speaker informed us there were several "more of us" in other compartments—a statement fully borne out on our arrival at Holyhead.

We duly embarked, and then began the transfer of the luggage. Well, I've seen luggage knocked about pretty considerably in my time, but nothing to be compared with this. It was simply disgraceful. One can understand there is not much time to spare, but that is no fault of the passengers. Better start a little earlier, or arrive in Dublin a little later, than get your luggage ill-treated like this.

A Traveller's Story.

I mentioned the matter to a gentleman I met in Dublin, but he did not seem to think much of it. "I've heard that same before, Sorr," he said, "but I don't know it. When I went to London awhile ago with my brother-in-law and his wife, we took a trunk with us that had been in the family for generations. Well, Sorr, when we came back again, after three weeks, that ould thrunk was as good as new!" Notwithstanding this story, I recommend all conventioners not to let their cameras or plate-boxes out of their possession.

The journey over was fairly good; the boats commodious (although infinitely inferior to those running at the present time), and beyond some of us looking a little pale, we were none the worse when, in the early morning, we came in sight of beautiful Dublin Bay; a slow journey up the Liffey, and then we made fast at North Wall. A jaunty car (hold tight, please!), and in a few minutes (and, of course, an argument with the car driver) we were comfortably housed at Hammam's. By-the-bye, attached to Hammam's there are Turkish baths. These were such a fascination to one of our members that he had one every day, sometimes two. By the end of the week his weight had been considerably reduced—he could button his waistcoat the whole way down, and wear his dress suit without discomfort.

Observant Church-goers.

Sunday.—It need scarcely be said that the Executive of the Convention never attempts to exercise any direct influence over the

members with regard to their devotions. Whether they are Protestants, Catholics, nothingites, or belong to the various sects which the Irish sergeant called "fancy religions," they "gang their ain gait," and go anywhere or nowhere, according to their own sweet will. Still, whether it is due to the excellent example set them by members of Council or not, one thing is quite certain, viz., if they arrive on the Saturday or Sunday morning previous to the Convention, their attendance at the more important churches is a very noticeable feature; and in this respect the Dublin meeting was all that could be desired. Some went to Christ Church, some went to the Cathedral, some to both, and seemed all the better for it—at any rate, photographically. The way they went to the best spots the next day and planted their cameras unhesitatingly in the various naves and aisles was little less than inspiration.

There are some excellent pictures to be obtained in both the above-mentioned edifices. Christ Church—restored a few years ago by a Dublin merchant at a cost of something like £25,000—is a very fine building, with a very fine organ. St. Patrick's Cathedral—with its memories of the eccentric Dean Swift—is also very interesting, and an entire day could be well spent in either of these buildings.

Possibly the verger at the Cathedral is not the same now as in 1894. The gentleman who obligingly explained things to us at that time was so mixed in his dates that we had to come to the conclusion that in some instances the windows had been put in before the church was built.

Penalties of Fame.

One incident on this particular Sunday I have never forgotten. I have mentioned before that the Hotel Metropole was regarded as headquarters. Passing there about six o'clock, we were surprised to find quite a number of people looking up at the first-floor balcony. The road was partially blocked by jaunting cars, and everybody seemed on the tip-toe of expectation.

There is a story told by a lady member of the Convention that when she was going away for her honeymoon some years ago, she was much perturbed because every time the train stopped at a station she heard the church bells ringing a merry peal; she naturally connected it with her wedding day, and quite forgot the fact that it was our late Queen's Jubilee. Just in the same way I concluded this excitement must have to do with the Convention, and felt quite flattered at the interest taken in it by the populace. I had during the day heard that the Lord Mayor had invited the members to a garden party at Killiney, and thought possibly he had come to our headquarters to make the personal acquaintance of some of our principal members who were staying there—or, possibly, it was the people's appreciation of our President, Sir Howard Grubb, who had called to see some old friends.

More people, more Jarveys, more shouting. On the balcony stood many prominent conventioners, including (if I remember rightly) Messrs. York, Cembrano, Cox, Lawley, Traill Taylor, Henderson, Kidd, Howson, Cowan, Welford, Stuart, Keene, Fall, Hindley, Sturmev, etc., all looking pleased and interested. After some further delay and manifest impatience on the part of the crowd, the centre door of the balcony opened, and there stepped forward a strapping young fellow of about thirty. His appearance was greeted with deafening shouts, waving of handkerchiefs, and whips. The uproar was terrific. It was a little puzzling—not Sir Howard Grubb, evidently; must be the Lord Mayor. So I remarked to a gentleman standing near. "Rather young for the Mayor of a large city like this, isn't he?" "Mayor!" said he; "don't you know who that is? That's Corbett, the prize-fighter!"

(Curtain.)

F. A. BRIDGE.

[Further reminiscences of the 1894 Convention will appear next week to strengthen the intentions of any who may not yet have finally decided on going to Dublin this year.—E.S., B.J.P.]

AN APPEAL TO CHARITY.

THE MAWDSLEY FUND.

WE are glad to record a liberal response to our appeal of last week for Mr. Peter Mawdsley, who now, at the age of eighty years, finds himself without the means to provide those slight comforts which his present illness renders all the more necessary. It is our pleasant duty to thank those who have lent a helping hand to our old friend in his distress. We have been in communication with the Rev. Canon R. F. G. Smithwick, who has been good enough personally to interest himself in the case, and to whom we are indebted for assistance in the administration of the money. A small sum has been disbursed to relieve immediate necessities, and we will announce in a later issue the manner in which it is proposed most advantageously to apply the total sum which may be subscribed. As announced last week, any small donation may be sent to ourselves or to Canon Smithwick. The following are the further donations received up to going to press (Wednesday morning):—

FORTHCOMING EXHIBITIONS.

May 10 to June 19.—Salon of the Photo Club de Paris. Secretaries, Paul Bourgeois, 44, Rue des Mathurins, Paris.

July 4 to August 12.—Northern Photographic Exhibition. Secretaries, F. G. Issot, 62, Compton Road, Harehills, Leeds.

July 15-25.—Sixth International Salon Association Belge Photographie, Liège. Secretary, Mr. Servais, 34, Rue du Sai Esprit, Liège.

September.—Royal Photographic Society, New Gallery, Regent Street, London, W. Secretary, J. McIntosh, 66, Russell Square, London, W.C.

October 28-November 4.—Sheffield Photographic Society. Joint Hon. Secretaries, J. W. Charlesworth, 1 Joshua Road, Sheffield, and James W. Wright, 62, Vale Road, Sheffield.

November 14, 15, 16.—Ipswich Camera Club. Hon. Sec., R. Sutton, 37, Henley Road, Ipswich.

November 21-25.—Southampton Camera Club. Hon. Secretaries, S. G. Kimber, Oakdene, Highfield, Southampton.

December 1-6.—Hove Camera Club. Hon. Secretary, A. R. Squant, 55, The Drive, Hove.

December 12-20.—Southsea Photographic Society. Hon. Secretaries, F. J. Lawton, 5, Pembroke Road, Portsmouth.

March 3-10, 1906.—South London Photographic Society. Hon. Sec., H. Creighton Beckett, 44, Edith Road, Peckham, S.E.

March 6-20, 1906.—Glasgow Southern Photographic Association. Hon. secretary, William H. Frame, 28, Bank Street, Hillhead, Glasgow.

FORTHCOMING COMPETITIONS.

June 15.—Warwick. Money prizes for members of photographic societies for pictures taken on Warwick Dry Plates. Warwick Dry Plate Company, Warwick.

September.—Kodak. £400 in prizes for results on Kodak products Kodak Ltd., 57-61, Clerkenwell Road, London, E.C.

Photo-Mechanical Notes.

Orthotype—Vilim's Asphalt Grain Process.

Under this title, Herr J. Vilim, of the well-known printing establishment, "Unie" of Prague, has patented a process of half-tone on metal or stone, in which the light-sensitiveness of asphalt is applied and an ordinary negative is used. The process is described in the current number of the "Zeitschrift für Reproduktionstechnik" by Herr J. K. Vilim, who points out that several experiments have been previously made in this direction, and notably by Lemerrier, Leresbours, Barreswil, and Davanne, of Paris, in 1853, who worked with a thin asphalt solution on stone; this did not give a varnish, but a grained surface, which was due to the porosity of the stone.

In the same year MacPherson, of Rome, experimented in a similar way; he was the first who broke up the closed tones of photographic negatives by grained surfaces. Other methods were those of Poitevin and Lemerrier in 1856, the details of which were not published, and which led to no practical results, and are therefore only of historical interest.

The principle of orthotype is founded on the fact that a solution of asphalt in chloroform is precipitated by the addition of alcohol and forms a grain.

Asphalt consists of two substances, both of which are soluble in etherial oils, but the one more easily than the other. These can be separated by mixing chloroform with alcohol; the easily soluble constituent dissolves in the alcohol, the insoluble is precipitated, and this is less sensitive to light.

If asphalt is dissolved in chloroform and alcohol added, a certain quantity of the black insoluble asphalt is precipitated, corresponding to the amount of alcohol added.

If the solution is coated on a flat surface and dried, there remains on the support a black and yellow grain. The quantity of the latter depends upon the purity of the asphalt; some is always necessary, otherwise the image would be broken up. The grain consists of fine serpentine lines which cannot be seen by the naked eye.

Although the mixture of chloroform and alcohol was well known as a solvent of asphalt, it has not been practically used. This solution cannot be flowed over smooth surfaces, as the chloroform and alcohol repel one another. In order to obtain a smooth coating some ether should be added. The solution then flows smoothly, but dries in an amorphous condition, and does not withstand an acid etch. The requisite hardness of the film is only obtained by the addition of some benzole.

The formation of the grain is dependent on the action of certain solvents at given temperature and duration of action. For orthotype, Syrian asphalt is the best; hard blue litho stones are preferable to the soft.

The light-sensitive solution is prepared by dissolving, by constant agitation, asphalt in chloroform with the addition of benzole, alcohol, and ether in the proportions of 2:20:2:8:10.

Zinc and copper plates are prepared with this solution in the same way as for the ordinary half-tone process. The plate to be coated is placed by yellow light on a stand, which is either fitted with a semi-spherical head (to facilitate its handling) or else on a stand with arms which will enable it to be moved vertically or horizontally.

The plate must be carefully freed from dust and coated with the asphalt solution, which should have been filtered several times. This operation is done in a similar manner to coating glass plates with negative emulsion, save that the coating must be done quicker in order to obtain a regular grain.

The grain obtained with the above solution is suitable for lithography on account of its fineness; for bookwork a coarser grain is required, which is obtained by the addition of a little alcohol. A very important factor in the manipulation is the temperature which should vary from 60 deg. to 85 deg. Fahr. After coating, the prepared surface must be exposed to the vapour of benzole, which is effected by flooding a glass plate covered with blotting paper, which should be inverted over the prepared surface at a distance of about 1 centimetre. Too strong an action of the benzole has the same disastrous results as an excess of benzole in the asphalt solution. The grain then becomes rounder, and is enlarged till it finally becomes quite flat.

The plate is now ready for printing, which is effected under a reversed negative, of about the same quality as is required for collotype, so that the grain in the dense parts does not run together. This principally applies to monochromatic black reproductions.

Printing with a normal negative in sunlight takes about an hour.

For development, rectified French oil of turpentine is used, or the ordinary if it does not contain resin, petroleum, or benzine, which residues would be thrown down in washing, and would form a precipitate between the grain on the stone or zinc, with disadvantageous consequences. In order to accelerate development, as well as to increase the quality of the image, an addition of benzole to the turpentine may be made, but this should not exceed one-third of the total volume, and the correct temperature should also be maintained.

Development is effected by light treatment of the plate or stone with a soft pad, or, better still, by merely pouring the turpentine and benzole over the surface as in the wet plate process. As soon as the image appears, the plate should be washed under a strong stream of water and dried with damp filter-paper, so as to retain the details.

It is advisable, especially if the printing has been done in a bad light, to expose the plate before development to the vapour of turpentine. The more exposed places absorb less, whilst the less exposed places absorb more of the turpentine vapour, so that the image appears equally lightly put on the surface. In this case the plate is again exposed to the sun for a quarter of an hour before development, by which means the shadows are strengthened and give a greater resistance in development; they then appear more contrasted and more closed up.

Development may be interrupted at any time without harm, and, after rinsing, may be continued in parts or wholly.

Different parts may be protected with gum to which a little honey should be added to prevent the gum drying too quickly and to counteract the splitting of the asphalt film.

If the retouching is repeated, water should not be used, for the intermediate rinsing of the gum would be washed away, and it should be merely dried off with a pad of linen. Thus the plate may be covered five or six times, which is a great advantage for colour printing.

When the plate is developed it should be exposed to the sun, then allowed to cool, and washed.

The further treatment is normal; the stone is etched, washed, dried, and left for five or six hours under the gum; this then washed away with water, the asphalt removed with turpentine, the printing ink rolled on the stone, and this again washed off.

The Process Workers' Trade Union.

We have before us the annual report of the Amalgamated Society of Lithographic Artists, Designers, Engravers, and Process Workers, which shows that in spite of bad trade the society has made progress during the past year, its nineteenth, having admitted 206 new members (or, allowing for deaths, etc., has a net gain of 107), while its funds have been increased by £597, and its total assets now stand at £5,774.

The record of work accomplished is certainly a considerable one, and includes particulars of the superannuation, sick, and unemployed benefits which are available to members' subscription. The society contemplates taking a London office, and meanwhile has appointed an organising secretary for the South, Mr. F. C. Tolhurst, of 102, Clapham Road, London, S.W.

The Union and Technical Education.

The society has always been friendly to technical education, as stated in their rules, and evidenced by the fact that they helped to initiate the L.C.C. School of Photo-engraving in Bolt Court; but they view with some alarm the formation of process classes at many industrial centres without due regard to the condition of the trade at those places, thus tending to add to the number of apprentices, when there may already be too many. Bradford was a case in point, and therefore the society approached the Education Committee, and induced them to frame some regulations concerning such education, which are acceptable both to the society and the employers of that district—an eminently satisfactory result of such common-sense action.

Town versus Country.

Some of the principal firms producing three-colour work are finding it advantageous to be out of the London smoke. Thus the Hentschel Colourtype have separate works at Norwood; the Anglo Engraving Co. do their colour work at Raynes Park, Wimbledon; and Messrs. Dent and Co. have their works at Clapham. In the recent colour postcard case, the Anglo Engraving Co.'s work was evidently looked upon as excellent, since the defendant produced a postcard done from the same subject to show how much better the work could be than that with which he had been supplied!

PHOTO-MECHANICAL PATENTS.

Application for Patent.

10,175. Bogdan Gisevius, 7, Southampton Buildings, Chancery Lane, London. Improvements in and relating to the manufacture of printing plates.

10,803. A. J. Boulton, 111, Hatton Garden, London, for Franz Otto, Munich, Germany. Improvements in or relating to photo-mechanical colour printing.

Printers, and probably some process-men, will be glad to be informed of the appearance in the "Allgemeiner Anzeiger für Druckereien" of a list of German synonyms of technical and shop terms used in the printing trades. Even the general reader may obtain some relaxation in a study of the dictionary. We see it stated that "to rat" (whatever that is) is equivalent in Germany to "unter Tarif arbeiten."

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

The following applications for patents were made between May 22 and 27:—

DAYLIGHT DEVELOPMENT.—No. 10,630. Apparatus for developing photographic dry plates in daylight. Albert Hawkins Clark, Ferncliff, Goodwin, Pembrokeshire.

LANTERN CONDENSERS.—No. 10,799. Improvements in the mounts for condensing lenses of optical lanterns. John Frank Brockliss, 115, Cannon Street, London (La Société Romanet et Guilbert, France).

COLOUR PHOTOGRAPHY.—No. 10,900. An invention for producing photographic prints in natural colours from negatives obtained by the ordinary trichromatic process of photography. Edward Ferdinand Grün and George Albert Smith, The Hall, Southwick, Sussex.

PACKING.—No. 10,955. An improved light-tight packet for photographic sensitised surfaces. Oscar Becker, Birkbeck Bank Chambers, Southampton Buildings, Chancery Lane, London.

MAGAZINE DARK SLIDE.—No. 10,956. An improved magazine dark slide for photographic cameras. Oscar Becker, Birkbeck Bank Chambers, Southampton Buildings, Chancery Lane, London.

COPYING APPARATUS.—No. 10,974. Improvements in quick copying or printing apparatus for reproducing photographs. Ferdinand Oppenheimer, 322, High Holborn, London.

PRINTING PAPERS.—No. 11,077. Improvements in the preparation of photographic printing papers or surfaces. Karl Pfanz, 111, Hatton Garden, London.

COMPLETE SPECIFICATIONS ACCEPTED.

Specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

COLOUR PHOTOGRAPHY.—No. 15,204, 1904. The claim is for a box-accessory, to be fitted to the back of a camera (or itself used as a camera) and containing a red screen at an angle of 45 deg., which screen, C, transmits light to the red sensitive plate, D, at back, and reflects light to the green and blue sensitive plates at D¹. These two plates are placed film to film, separated prefer-

ably by a thin, yellow colour screen, or a yellow screen is placed in the direct path of the rays entering the camera. William Norman, Lascelles Davidson, 20, Middle Street, Brighton.

COPYING DRAWINGS, ETC.—No. 1,753, 1905. The claim is for an apparatus consisting of a rotating transparent cylinder, illuminated from within, round the outside of which the negative and sensitive papers are carried by a number of small bands carried over rollers. Hans Vigo-Stim-Jensen, Blegdams Hospital, 1, Blegdamsvej, Copenhagen, Denmark.

The same patentee claims protection for a very similar apparatus in Patent No. 1,757, 1905.

FLASHLAMP.—No. 4,326, 1905. The construction and mode of action of the lamp are as follows:—The door G is pulled down into its horizontal position against the influence of spring I. A charge of powder is then placed in the tray E, and the wick of the pilot lamp H is lighted, it being understood of course that the glazed front B of the lamp is closed, and the gauze D is either closed up against this front or left hanging down according to the effect desired. When everything is ready for the exposure to take place the pneumatic ball L is squeezed so as to inflate

the bellows K, which thus actuate the catch J, and the spring I then contracting pulls the door G to, and the flame of the pilot lamp H coming into contact with the charge of powder fires it, thus giving the flash. As the door G bangs to also simultaneously with the firing of the powder or probably a little in advance thereof, the door rebounds by virtue of its own elasticity so that at the moment that the explosion is taking place there is a clear way for the expanded gases. It is found in practice that with a lamp about one foot high by eighteen inches across and about eight inches from back to front it is possible to fire about two and a half grammes of explosive without danger and without vitiating the atmosphere surrounding the lamp. Marwood Short, 1, Victoria Colonnade, Ramsgate.

The following complete specification is open to public inspection before acceptance under the Patents Act, 1901.

SMITH.—10,372. Manufacture of films for photographic and other purposes.

VISITORS to the Continent who desire to send picture postcards to this country may be glad to learn that the Postmaster-General, in a recent letter, has admitted the legality of sending such cards for one halfpenny, provided "postcard" or its equivalent is struck out, and the words "printed papers" substituted. Many travellers, observes "The Globe," have been for a long while making use of this concession, which, however, is not so widely known as it deserves to be. With the alteration mentioned, a card can be sent to or from the Continent for a halfpenny so long as, in addition to the name and address of the recipient, it bears only the name and address of the sender and the date.

New Apparatus, &c.

The Planastigmat Portrait Lens. Sold by Messrs. A. E. Staley and Co., 19, Thavies Inn, Holborn Circus, London, E.C.

To their series of Planastigmat lenses, Messrs. Staley have now added another—the Portrait Planastigmat, made in six sizes from 7 to 15½ in. focus. That submitted to us for examination is the No. 3, of 10½ in. focus, and specially adapted for cabinet portraits in short studios where the use of a lens of longer focus would be inadmissible. Inspection of the instrument shows us that the front combination is a cemented rather deep meniscus. The back component, as in the Petzval lens, has an air space, but the elements are differently arranged—practically reversed.

On testing the lens with its full aperture ($f/3$) we find that it yields remarkably good definition over a wide area in proportion to its focal length, and has a greater equality of illumination over the whole field it is intended to cover than is the case with the general run of portrait lenses of the Petzval type. The field is very flat, and the astigmatism is reduced to a minimum, rendering it an excellent lens for portraiture. With slight stopping down the lens will cover the whole plate well to the edges.

A good word may be said for the mounting, which is of aluminium in the more bulky portions, the tube itself being of brass. The diaphragm is of the iris pattern, and permits of the lens being stopped down to $f/36$.

Our general conclusion is that the Portrait Planastigmat can be recommended to any one wanting a really good and rapid portrait lens at a moderate price. The lens submitted to us is listed at £13 10s

New Materials.

Revoli's Magic Photo-Tints. Sold by Marion and Co., Ltd., 22 and 23, Soho Square, London, W.

Put up in convenient little pans, this new series of Photo-Tints is likely to be very popular. The colours include flesh, blue, yellow, brown, purple, magenta, pink, green, black opaque, and white opaque—sufficient for nearly every tint required for colouring photographs or lantern slides. A very useful list of suggestions for mixing the colours to obtain various other tints is given in the introductions. For instance, brick red can be obtained by combining brown and magenta; French red, by mixing magenta and flesh; drab, by adding yellow to purple; and so on; in addition to which, another list is given showing correct colour harmonies and contrasts most useful to photographers whose sense of colour is not all that it might be. The colours are easy to apply, and are very pure and brilliant, so it is necessary to use them very dilute. A little of the solid colour is taken and dissolved in water. The fluid tints should be kept in separate saucers, and not allowed to mix. The photographs should be made surface-damp, and the colour applied in thin washes with a camel's hair brush. Extra moisture should be removed with blotting paper. A point in favour of these colours is that they dry glossy on glossy prints and matt or matt surface papers. The tints should never be used full strength, but repeated washes should be given until the required depth of colour is gained. Collodion papers may be tinted immediately after washing, or by using a weak solution of Revoli's Medium. To obtain different shades of colour, a wash of one colour should be applied over another; the tints should not be mixed and applied, or muddy tones will result. The colours can be also applied with great effect in pyrography or

burnt-wood work." The set of ten colours is supplied in a neat box with full instructions at 1s. 6d. Not at all dear considering its usefulness.

"Eastman" Plates, Rapid and Extra-Rapid. Manufactured by Kodak, Ltd., 57-61, Clerkenwell Road, London, E.C.

Outside of Great Britain the "Eastman" plate has been actively marketed for a number of years, and the manufacturers are therefore not embarking on plate-making without the very essential qualification of a lengthy factory experience. As now issued to the British market, the "Eastman" plates have been modified, and, if we may speak from our tests of them, embody the very highest skill in emulsion making, as they evidence minute attention to the mechanical details of dry plate manufacture. Both brands of plate are exceedingly rapid, and, in general behaviour, the two are very similar. We were particularly anxious to put the "Extra-Rapid" to the test, and, to that end, made hand-camera exposures with a focal-plane shutter at its maximum speed, with very satisfactory results, the subject being a street scene. The behaviour of the plate was such as well qualifies it for photographic work of the most rapid kind: the plate is thickly and evenly coated, and works in the cleanest manner. Messrs. Kodak, Ltd., apparently, are bent on making its virtues widely known, for their formulæ for development are given in the languages of the chief civilised countries, and also in Russian; and we have no doubt that the plates deserve the favours of photographers of every class. For the benefit of those who can appreciate sensitometric measurements, we may quote the following from a report of Mr. C. E. Kenneth Mees, B.Sc.:—" γ_{∞} (greatest possible steepness of gradation, and a measure of the density-giving power of the plate) 2.76. K (velocity constant of development with standard ferrous oxalate) .047 = 94 minutes for a standard gradation of 1. Opacity of the plate to blue light (index to latitude) 15. Coating, good. Extremely clean, quite free from fog. Grain, fairly good. A most excellent plate." The figure obtained by Mr. Mees for inertia (H. and D. pryosoda) is .100, which gives, it will be seen, a very high speed reading to the plate. In fact, this number for inertia is appreciably lower than that obtained by the makers, viz., .123, low inertia giving, of course, a higher speed number. The difference is considerable, but may easily be due to several things. Whichever is taken as correct, the figures demonstrate a very high degree of rapidity.

THE WATKINS SPEED CARD.—The Watkins Meter Co., of Hereford, announce that in future they will send, for a subscription of 1s. per year, a series of the latest speed cards to be used in conjunction with the Watkins Meters. These cards, of which eight will be issued during the year, show the latest speed readings of the various makes of plates, and are brought up to date as new batches of plates are put on the market. The cards, we understand, are issued without any guarantee, implied or expressed, as to their correctness. They merely claim to be a bonâ fide record of independent tests by the Watkins Method.

COLLODION Explosion.—On four workmen employed in M. Oudinot's photographic laboratory at Nancy remarking that a carboy of collodion was leaking, they proceeded to pour the contents into another vessel, without noticing that they were close to a lighted stove. An explosion took place, followed by an outbreak of fire, which was, however, speedily extinguished. Three of the workmen were terribly burnt (the fourth threw himself into a neighbouring pond), and one has already died.

ETHER Explosion.—An explosion took place a few days ago in a pharmaceutical-specialty manufactory at Aix-les-Bains, belonging to M. Dussel, who is a member of the French Parliament. It appears to have been due to the ignition of the vapour of ether. Four workmen were seriously burnt.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

June.	Name of Society.	Subject.

ROYAL PHOTOGRAPHIC SOCIETY.

Meeting held June 6, Major-General Waterhouse in the chair. Miss Sarah A. Acland read a paper on "A visit to Gibraltar, demonstrating the use of three-colour photography in giving a more favourable impression of a place than can otherwise be obtained." Miss Acland's paper did not belie its title. It was very slightly technical, but described in a pleasant conversational style visits paid to Gibraltar, and excursions made by permission of the lecturer's brother, Admiral Acland. The bulk of the illustrations were three-colour slides by the Sanger Shepherd process, and it is no exaggeration to refer to Miss Acland's work as the finest which has ever been publicly shown. In the subjects which lay close to hand on the rock of Gibraltar the lecturer had full scope for the demonstration of the capacity of the tri-colour process, and in comparison with the monochrome rendering of similar scenes the case for colour required no emphasis. Many foreground studies of the luxurious flora of the rock were magnificently reproduced, as were also a number of portraits and several studies of gipsies, Moors and Moorish boys. We would add a special word of praise for the rendering of some scenes in which the colour of the subject came nearer to neutral tints. Certain slides of the sea in grey weather were in excellent tone, and are a severe if less realistic test of the lecturer's mastery of the process. In so far as Miss Acland strayed into techniques she said that her exposures were made on Cadett "spectrum" plates, the times for the blue, green, and red screens being, on the average, in the ratio of 2:6:30. She found it necessary to verify this ratio with each batch of plates, and she found it to alter with time, on the plates being kept. Her test object when determining the times was a piece of white paper and a small bow of red, white, and blue ribbons. The developer used throughout was metol, controlled by time. The exposure through the blue screen was found to be about ten times that required by the unscreened plate, so that in using plates by actinometer, her usual practice, a H. and D. number one tenth that marked on the box was taken. In developing the transparencies it was found best to let them remain as still as possible in the development water, if there was to be good rendering of fine detail. The difficulty of cementing the celluloid monochromes, complained of by some, was not experienced if a little Canada balsam as possible was employed.

A hearty vote of thanks from a large audience brought the meeting to a close.

SOUTH AUSTRALIAN PHOTOGRAPHIC SOCIETY.—The annual exhibition of photographic work for the present year will be opened on September 11. A bronze medal is offered for competition in each of the nine classes of Section 1, or in lieu thereof the sum of one guinea. A silver medal is offered for competition in each of the

eight classes in Section 2. The society offers a gold medal as a champion prize, in lieu of any other prize for the best picture in Sections 1 and 2, such picture to become the property of the South Australian Photographic Society. All exhibits must be delivered at the South Australian Society of Arts' Rooms, Institute, North Terrace, Adelaide, not later than August 30, 1905.

THE SCOTTISH PHOTOGRAPHIC FEDERATION EXCURSION.—On Saturday, the annual excursion of the Associates of the Scottish Photographic Federation was held to Blairgowrie. The arrangements were left in the hands of a local committee. In the forenoon a drive took the party to Meikleour, with the famous Beech Hedge, Kinclaven Castle, the Market Cross, the Jongs, etc. Clunie Loch, then home via "The Lochs" to Blairgowrie. The civic head of the burgh, Provost Smith, welcomed the visitors. President Macdougald, in reply, referred to the good work the Federation had done, and the work it yet hoped to do. The societies in Scotland, instead of being scattered units, were now parts of an enthusiastic whole, working for the betterment of photography in Scotland.

NORTH MIDDLESEX PHOTOGRAPHIC SOCIETY.—Mr. Charles Beadle, the president of the North Middlesex Photographic Society, gave an interesting lecture last week before the members on "The Production of Enlarged Negatives." His method of procedure is as follows:—From the original small negative a positive is made, preferably in carbon; the object being in all cases to get a transparency giving full detail in the shadows without brilliant high lights. If a dry plate is used for the positive, then one with a speed of Watkins 35 to 40 is the best. With a negative of average density placed behind a piece of opal glass the exposure required is about 20 seconds, 12 inches from a kerosene lamp burning half-inch wick. The developer is pyro-soda, without bromide, of a strength of 2 grains pyro to the ounce. For the enlarged negative a plate of the same speed is used as for the transparency, and the same developer is employed. Exposure is regulated in conformity with the density of the positive and the size to which it has to be enlarged.

Commercial & Legal Intelligence

CATALOGUE DISPUTE.—At the City of London Court on Friday last, the Rotary Photographic Company, Limited, New Union Street, Moorfields, sued Mr. O. T. Banks, dealer in electrical fittings, 49, Mortimer Street, for £4 17s. 6d., the balance of £25 17s. 6d. for printing a catalogue. Plaintiffs agreed to print 100 trade catalogues for the defendant for £30. They were well done, but only 92 were printed. Plaintiffs charged for the 92 at the same rate as they would have been paid for the 100. It was well known in the trade, they alleged, that a margin was always allowed both ways. Defendant said he wanted 100 catalogues. He counterclaimed for £5 as damages for not having the full number. The Judge found for the plaintiffs for £10 on the claim, and for the defendant for 1s. on the counterclaim.

At the Leeds Bank Court last week, Cecil Montague Stafford, photographer, 5, Nassau Place, Leopold Street, and carrying on business as Cawkwell and Stafford at 2, Commercial Street, Leeds, appeared for examination. His liabilities were £634 5s. 9d., and assets

Numerous postcards enclosed in transparent covers, with the address written upon the enclosures, have recently been observed in the post. Transparent covers are a source of embarrassment to the Post Office, and the Postmaster-General has decided that correspondence sent in such covers, with the address written upon the enclosures, is to be withheld from delivery, and sent to the Returned Correspondence Office, marked "Contrary to regulations."

News and Notes.

THE Ilford £750 Competition.—The judges made their awards last month, and the prizes were duly forwarded to the successful competitors. Further details will be given in the July number of "Photographic Scraps."

THE Brighton Corporation Exhibition of British Pictorial Photography, closed on June 3. During the six weeks it was open it was visited by upwards of 26,000 persons.

MR. J. F. BENSON, of 7, George Street, Stroud, writes us to the effect that the following goods were stolen from his studio on Sunday, May 14 last, and wishes to caution photographers against having dealings with any person offering these goods for sale, viz:—A perfectly new mahogany folding outdoor view camera (1-1 size, City Sale and Exchange make) in brown canvas case, and brown canvas strap and nickel-plated patent lock, three double dark slides, and other goods to the value of £10.

DEATH of the Liverpool Police Photographer.—Mr. William Malley Gregson, the well-known photographer attached to the Liverpool Police Detective Force, expired somewhat suddenly last week at his residence in Fazakerley. He was about thirty-four years of age, and was well known in connection with criminal photographic work. He had seen about ten years' service, and was looking forward to a career of usefulness and distinction. So late as Monday in last week he was at the office in Dale Street, and appeared then to be in his ordinary health. He was taken rather suddenly ill with colic, and, in spite of every effort and attention, death took place, to the regret of a large number of friends. An operation was performed in the hope of saving the life of the deceased official, but he did not rally from it. Deceased leaves a widow and several children to mourn his loss.

The result of the Warwick competition for May is as follows:—First prize (£10), W. Northwood, Esq., Wordsley, Stourbridge; donation (£5), to the Brierly Hill and District Camera Club; second prize (£5), A. H. Avery, Esq., 319, Queen's Park Road, Brighton; donation (£2 10s.), to the Hove Camera Club.

SOUTH London Photographic Society.—For the benefit of the less advanced members this Society has instituted a series of monthly progressive competitions, to be held during the winter session. In order to give plenty of time to enable members to take advantage of summer holidays, the list of subjects chosen for the session will be announced some months before the first competition is held. Special judges are appointed for each subject, and a progress medal (bronze) will be given to the competitor gaining the highest aggregate by the end of the season.

CONTINENTAL EXCURSIONS for the Whitsun Holidays.—Mr. W. F. Slater has sent us particulars of a photographic excursion to Bruges and Flanders from June 10 to June 17. Announcements of other excursions to the Continent are also included. Full particulars will be sent on application to Mr. Slater, 84, Longhurst Road, Lee, S.E.

THE Great Northern Railway of Ireland send us an excellent illustrated tourist and excursion programme for 1905. It is a book of considerable proportions, is full of information concerning interesting places in Ireland, and is well illustrated. The particulars of excursions should be exceedingly useful to all tourists in Ireland this year.

In the current number of "Arts and Crafts" a writer draws comparisons between the work of artists who make use of photography and of those who do not. While decrying the use of photographs as an aid to drawing and painting, their utility is acknowledged. He says:—An excellent test of his work may be suggested

to the student who can be trusted with a camera. We say advisedly "trusted," for there is nothing more detrimental for the young painter than to copy, with its inevitable exaggerations, a photograph from nature. Let him first make a drawing or colour sketch—preferably the latter—and then take a photograph of the identical subject, making the picture plane within the same limits, as nearly as possible. On comparing the two, there will be many surprises in store for him, agreeable and otherwise; the latter, because he will see how clumsy his drawing of the structural forms is when placed beside the faithful transcript made by the camera; his granite rocks look like dumplings beside these hard, time-polished boulders traced by the sun; while the seams and scars which mark their weather-beaten sides, so full of significance to the geologist, are merely meaningless lines mapped out upon a formless surface in his sketch. Of course, this will be most discouraging, but it will teach him much. In the first place, his compensation will be a certain grace gained by the suggestion in his sketch, where he has chosen the beautiful and ignored the ugly details in what lay before him. The photograph copied all, both good and bad, and the artist who in turn copies the photograph is apt to assimilate as much of one as the other—perhaps more of the latter—and will surely be betrayed by the false aerial perspective and violent foreshortening, which will distinguish the disguised copy from the intelligent work of the freehand draughtsman. Another cause of misrepresentation in the photograph is the confusing distortion of values, consequent upon the tendency of certain light colours to register themselves as dark, and of others of dark complexion to assume under this influence a paler tint, untrue to nature. Lastly, it may cause him to lay aside his camera in despair, and this is something gained at once; for far more artistic is even a faulty sketch from nature, with a grain of truth in it and some beauty, than the most careful representation of the same natural facts when copied from a photograph.

AN Aerograph Exhibition is shortly to be held in London as the sequel to a competition in which 100 guineas is being offered by the Aerograph Company, Limited, for work of various kinds executed with the aerograph. The classes are:—Freehand drawings, photo portrait finishing, finishing for process, aerograph litho work, window tickets or show cards, Christmas cards, decorations on silk or cloth, jewellery and metal ditto, coloured lacquers or enamel, decorations on pottery, mural decorations; and the prizes consist of aerograph outfits and sums of money. They will be awarded by a jury consisting of J. Martin Wood, Esq., of the editorial staff of "The Studio"; William Gamble, Esq., editor of "The Process Year Book," and George E. Brown, Esq., THE BRITISH JOURNAL OF PHOTOGRAPHY. In its preliminary circular the Aerograph Company intimates:—"In a great many classes of work the aerograph is combined with ordinary brush work or other methods; for the most part the awards will be for work displaying the best use of the aerograph, but not necessarily executed entirely with it. Exhibits will be received, unpacked, and packed for return by the company. No liability will be incurred for loss or damage by the company, but the greatest care will be taken of everything entrusted to them. As there may be a limited amount of space for exhibits, early notice from those intending to exhibit is desired. Notice will be given later of the place of holding the exhibition."

ONE HUNDRED Pounds for a Photograph.—Under this alluring title the proprietors of the "Strand Magazine" announce in the current number of that popular publication, particulars of a novel prize competition. Four reproductions of famous portrait paintings are given, and the prizes, which consist of £100, £30, and £20, will be awarded to the photographer who sends the best photograph, taken with the assistance of costume models, and suitable accessories, etc., most closely resembling one of these four originals. The lighting of the picture, the pose of the sitter, the costume, and, as

far as possible, the features and expression, will all be taken into account. The prizes will be divided equally between the sitters and the photographers of the winning prints.

CHANGE of Address.—Mr. Walter D. Welford has removed to Alston Lodge, 61, Mansfield Road, Ilford.

THE engagement is announced of Mr. Alexander Keighley, the well-known amateur photographer, of Keighley, and Miss Lily Hawroyd, of Bradford.

THE Ubiquitous Press Photographer.—While the business of rigging up the boom at Portsmouth harbour was being rehearsed the other day, stringent measures were taken by the police to prevent the work being photographed by unauthorised persons; all amateur photographers who were seen on the spot were ordered by the harbour police to put away their cameras. It is, therefore, somewhat astonishing, remarks "Truth," to find in the London illustrated papers pictures of the whole operation, including the special permanent fittings for securing the shore end of the boom, with a note attached that they are from photographs taken by a local professional photographer. Obviously this photographer could not have done his work in secret; and it is highly characteristic of the muddle-headed way in which our authorities go to work to secure secrecy, when they think it desirable that a professional photographer should be allowed to take large and elaborate views of the whole proceedings for the purpose of publication. An officer from whom this information was obtained states that the photographer in question makes it his business to supply photographs of guns, coaling apparatus, submarines, etc., to foreign papers, as the authorities must be aware, if they take the trouble to acquaint themselves with the contents of foreign military and naval journals. It certainly shows an almost chivalrous generosity on the part of our authorities if under these circumstances they give the photographer special and exclusive privileges for photographing our dockyards and harbour defences.

HUNTINGDON and the Great Ouse, with St. Neots and St. Ives, are the districts dealt with in the latest volume from the Homeland Association, Ltd. The handbook is written by the Rev. H. L. Jackson, M.A., and the Rev. G. R. Holt Shafto, an unusual co-operation of the High Church vicar and the Wesleyan minister. Its object is to draw attention to a little-known and very beautiful stretch of inland river scenery that should appeal to every landscape photographer. The district described will also be interesting owing to its association with both Cowper and Cromwell. The volume is published at 1s., and contains an Ordnance map of the river on the one-inch scale. A full list of the Homeland Handbooks will be sent free on application to Association House, 22, Bride Lane, Fleet Street, London, E.C.

THE Great Eastern Railway Company's new handbook, "Summer Holidays," is an attractive little brochure dealing with the various holiday resorts on the company's system. It is beautifully illustrated, and the numerous full-page illustrations in colours are quite little works of art. They are fac-simile reproductions of water-colour sketches, and give prominence to some of the less known districts in East Anglia. Every prospective holiday-maker should obtain a copy from the publishers, 30, Fleet Street, E.C.

"PRACTICAL Frame Making," by Colonel W. L. Noverre, forms No. 18 of the "Photography" Bookshelf Series issued by Iliffe and Sons, Ltd. The author deals in a practical manner with this important phase of finishing photographs for exhibition purposes, and gives full particulars and working details for the amateur frame maker.

No. 21 of "The Practical Photographer" deals with Orthochromatic Photography (simplified), and the subject is well treated from the practical, pictorial, and theoretical standpoints. A test chart in seven colours is included. The pictorial work of Harold Baker is the subject of the editorial.

Answers to Correspondents.

All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C. Inattention to this ensures delay.

Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.

For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

Palmer, 34, Oakland Road, Dovercourt. Two Photographs of His Majesty's King's Visit to Dovercourt.

West, 98, Victoria Road, Aldershot, Hants. Three Photographs of the King's Memorial to Members R.A.M.C.

Wray, 27, Chapel Street, Chorley. Photograph of Lady Balcarres Crowning the May Queen, May 25, 1905.

Mebaw, 41, Victoria Street, West, Grimsby. Two Photographs of Grimsby Rough Police Force.

IF.—1. Will you kindly inform me as to the best means of fixing crayon-worked bromide enlargements? I have tried the "Fixatif," on the market for black-and-white drawings, but find that it rests on the surface of bromide in a greasy stain. What I want is something that will fix without subsequent discoloration. If you can help me in this matter I shall be much obliged. 2. Will you also tell me what to use for P.O.P. prints in order to tint with aniline colours?

1. We cannot understand why the "Fixatif" gives the results you mention, unless the surface of the print is greasy. Is it the right kind, sold for the purpose? A solution of shellac in alcohol makes the best fixatif for the protection of crayon work on bromide prints. The following* is a good formula:—Pale-yellow shellac, 30 grs.; borax, 15 grs.; soda-carbonate, 5 grs.; glycerine, 15 minims; water, $\frac{1}{2}$ oz. Boil, cool, and add alcohol $\frac{1}{2}$ oz. Add pumice powder, to throw down lac wax, shake up, allow to stand two or three days, and filter. It is then ready for use. It should be applied in a fine spray by means of an ordinary scent diffuser, and if only sufficient is applied to lightly cover the surface of the work, no stains should result. The plan usually adopted by many workers is to hold the worked-up prints over the steam from a kettle of boiling water. This tends to slightly soften the gelatine, and the crayon work becomes firmly incorporated in the surface of the print when the film hardens again. A bronchial kettle is the best for the purpose. 2. There are many mediums sold for this purpose. Use purified ox-gall paste, 60 gr.; distilled water, 16 oz.; rectified spirit, 4 oz. Apply with flat camel-hair brush; when dry, prints will take both oil and water colour.

REIS.—1. Probably it would take about half an hour to wash the chloride out, but it should be left in. 2. If you washed the chloride out you would naturally get a brown stain at once. Perhaps you did not use distilled water—at any rate, you are using far too little chloride. You should allow about 15 gr. of chloride to every postcard, use citric (not tartaric) acid, and allow about 5 gr. of silver nitrate to each

card. 3. The temperature should be about 85 deg. F. It is obvious that you do not allow enough size, if you want a glossy card, and using such a strong silver solution, it penetrates through.

COPYRIGHT.—I have had a small print brought to me with a request to enlarge six copies. The photograph was taken by an amateur, who gave a few copies away to friends, etc. The photograph is a snapshot of three gentlemen (local celebrities), and I should feel extremely grateful if you can inform me:—1. Whether I can copy, enlarge, and sell prints. 2. Whether I can copyright same. The order I have in hand was from a gentleman, to whom one of the prints was given. 3. Can I sell copies without anyone's permission, or must I get the permission of the amateur who took the photograph of the three gentlemen?—Bos.

1. Certainly not; the copyright belongs to the person who took the photograph. 2. Surely you must know that you can do nothing of the kind. We should recommend you to study the Copyright Act. 3. You must not make any copies without the permission of the author of the picture. That is the law, and the owners of a copyright have power to enforce it.

COPYRIGHT.—I was out one day with my camera and came across a party of soldiers with a gun. I asked the officer in charge if I could photograph them. He gave me permission. I did so, and sold several copies. Last week I saw this same photograph (of which I hold the negative) reproduced in a London paper, and copyrighted. I regret to say that I had not copyrighted it. I suppose I have no claim against the paper for reproducing it, but have I any against them for copyrighting my work? An answer will greatly oblige. If I cannot claim damages against the above in either case, can I copyright the picture now, and, if reproduced again, can I claim damages?—SANDHURST.

You can register the copyright now and obtain an injunction against the paper, preventing them from issuing further copies containing the reproduction. You can claim damages for infringement before registration, but it is practically impossible for you to prove the damage. We think you cannot take any action for their employment of the word "copyright": see reply to W. H. J. E. on May 19. After registration you can take action for infringement.

W. ROSS.—1. Possibly Bourne and Co., 73, Ludgate Hill, London, E.C., would meet your requirements. 2. The "British Printer" (Raithby Lawrence, Leicester) and the "Caxton Magazine" (119, Finsbury Pavement, London, E.C.).

R.—If you will send your name and address we will reply to your query. We cannot undertake to answer anonymous correspondents.

PICTURE-FRAME MAKING.—I should be extremely obliged if you can tell me of a house that supplies gilders' whitening, as used in the manufacture of the compo picture-frames.—ANXIOUS.

The whitening used is that sold at the oil shops. Here is a recipe for the "compo": Boil 7 lb. of good glue in seven and a half pints of water; melt 3 lb. of pale resin in three pints of raw linseed oil. When the ingredients have well boiled, put into a large vessel and simmer for half an hour or so. When this is done, pour the mixture into a large quantity of sifted whitening, and mix to the consistence of dough. It is then ready for moulding.

COMPENSATION.—A certain newspaper has reproduced part of a copyright photograph of mine (a bust from a three-quarter length) without even acknowledging same. Please say

through your paper what would be reasonable compensation to claim.—J. E. HEYS.

As to the sum to be asked as compensation, that must clearly depend upon the commercial value of the portrait, etc. Of that we have no information whatever.

L. L.—Certainly it will, if made before publication.

BROMIDE and others.—In our next.

APPRENTICESHIP.—I have served four years' apprenticeship with a photographer, my period of apprenticeship expiring in May, 1904. The first year I received 3s. per week wages, second year 5s. 6d., third year 8s., fourth year 10s. At the end of four years I stayed on for five months for 16s. per week. I left in October, 1904, and since then I have not been able to obtain a permanent situation, as I have not been taught the business thoroughly. For three years I did the printing (P.O.P. only). I was never taught retouching or platinum printing. I was never allowed to try operating—in fact, all my knowledge of photography was self-taught. The result is I can only obtain a situation (with difficulty) as printer at about 25s. weekly. My knowledge of the business consists of printing, P.O.P., C.C., platinum, operating (poor), smooth up a negative, but not retouch as it should be done; developing bromide printing, fair. Could I bring an action for breach of contract with any prospect of success? My employer did not return my indentures at the expiration of my apprenticeship. Should he have done so?—ASSISTANT.

Your case is like scores of others where apprentices are taken solely for the purposes of getting work done for a quite nominal sum. A master is bound to teach an apprentice his trade, according to the terms of the indentures. If these were to teach you printing only, you have no real cause of complaint. But if you were to be taught photography generally, the law will give you redress. Much will depend upon the terms of the indentures. These it is usual to hand over to the apprentice at the end of his term. We should recommend you to consult a solicitor on the matter. We believe your late master can be compelled to produce the indentures in a court of law if called upon to do so. If the case be as you represent, you have, certainly, been badly treated, and should be able to obtain redress.

RETOUCHING.—1. Will you please give me your opinion as to the commercial value of work on accompanying specimen of retouching. 2. And in making application for situation I wish to know the remuneration I might reasonably expect for such work. The time taken to retouch the enclosed negative was an hour and a quarter. Thanking you for your favour.—WALTER S. CORDREY.

1. You ask for the commercial, not the artistic, value of your retouching on specimen print, and we presume that you mean as a trade retoucher. About 1s. 6d. for this quality work, but if done with really first-class finish it should command from 2s. 6d. to 3s. 6d., according to the generosity of the firm employing you. 2. Your second query is covered by our first reply from a trade retoucher's point of view, but if you refer to a weekly salary, then from 25s. to 30s. 3. For best finish a head of this size should occupy nearly two hours, but expert retouchers might manage it in one and a half hours or less.

AGENT.—You will see the advertisement of the agency in our outer pages. As to the insurance company, write the secretary, Professional Photographers' Association, 51, Baker Street, London, W.

PHOTOPHIL.—We cannot trace your previous enquiry. The two books on collotype are by Fithian (2s. 6d.) and Schnauss (both published by Iliffe and Sons).

Correspondence.

*** Correspondents should never write on both sides of the paper, notice is taken of communications unless the names and address of the writers are given.*

*** We do not undertake responsibility for the opinions expressed by correspondents.*

PANORAMIC CAMERA.

To the Editors.

Gentlemen,—In reply to your correspondent "Panormos" re camera to take a panoramic view of an entire circle," Messrs Demaria Frères, 2, Rue du Canal, St. Martin, Paris, make a special panoramic camera, and a special revolving stand top, and which, perhaps, is what your correspondent means.

If your correspondent will call on me I shall be pleased to show him illustrations and specifications.—Yours truly, J. MALLIA
285, Oxford Street, London, W., June 2, 1905.

PLATINUM PRINTERS' CATARRH.

To the Editors.

Gentlemen,—Reading the letters in the last two numbers of your journal re "Platinum Printers' Catarrh," I have been in business now five years, and until about two years and a half ago did nothing but albumen and bromide printing; since then I have done chiefly platinotype work. I do the whole of my platinum printing myself, and have been somewhat alarmed at the development of catarrh in my system, but have not attributed it to anything but constitution until reading "Old Platinum Printer's" experience. Yours truly, H. U. KNIGHT

The Studio, Cranleigh, Surrey, June 2, 1905.

SUNLIGHT DANGERS.

To the Editors.

Gentlemen,—Referring to the ignition of "dark slides wrapped in a black focussing cloth," is it not very likely that the focussing cloth was of black cotton velvet, a fabric almost as inflammable as flannelette, and which would readily be ignited by the focussed sun rays?—Yours truly, T. STOKOR

Clare, Suffolk, June 5, 1905.

*** NOTICE TO ADVERTISERS.—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.*

EX CATHEDRA.

The Trade the Convention.
The trade exhibition in connection with the Dublin Convention bids fair to include a very fine collection of professional photography. Among the prominent photographers Dublin who will exhibit may be mentioned Messrs. Layette, Alfred Werner, Chancellor and Son, Robinson and Son, Bradshaw, and probably W. Laurence. Messrs. and Walery have also booked space. The Platinotype Company will have a fine selection of work on view, will give demonstrations not only in development, but will take portraits by means of their new lamp. The Photolinel Company will also have a good show.

Monopoly in the Sale of Poisons for Industrial Purposes.
The projected Pharmacy Bill will, if it becomes law, create a greater monopoly in the sale of poisons used for industrial purposes than at present exists, by placing it entirely in the hands of pharmaceutical chemists. Recently the President of the Board of Agriculture and Fisheries received a deputation at the offices of the Board urging the amendment of the present Pharmacy Act, so as to legalise the sale of poisonous compounds, used largely in horticulture, by other than pharmaceutical chemists, who at present have a monopoly the trade. Chemical manufacturers and agricultural societies in England and Scotland were represented on deputation; and they pointed out the hardship to which farmers and others were subjected under the present state of the law, in not being able to obtain what they require at a cheap and ready market. In reply, the President stated that he considered it wrong that articles important to agriculture should be a monopoly, and he was strongly in favour of an amendment of the law in the direction suggested. He promised to take an early opportunity of

seeing what could be done in the matter. At present some of the poisons used in photography can only be obtained from a pharmaceutical chemist, and one has to pay a higher price for them than if they were obtainable from a photographic dealer. If the proposed Pharmacy Act is passed the sale of some other things used by photographers will be restricted to pharmaceutical chemists, who will then have a monopoly in them, and will doubtless charge accordingly.

Good Photography. How far the production of a photograph which is technically good is responsible for the diverting of much photographic business from the hands of the professional has never perhaps been duly considered. In portraiture, how many people care for perfect gradation, delicacy of modelling, pictorial arrangement of lights and darks or of line? The qualities demanded by the great mass of the purchasing public are characteristic and pleasing expression with good likeness, and an approximation to the ideal of masculinity or femininity. We are not decrying the production of a portrait with artistic qualities. They are a most valuable addition; but commercially in most cases only an addition. What we do wish to emphasise is that the wishes of the client must be met if business success is desired, and that photographers must learn to look further than at the mere manipulative excellence of their work. They must be more students of human nature than clever expositors, developers, and printers. Portraits are produced by the amateur in the home circle, and appreciated in many cases because they show the man as he is. Technical work is sometimes done by an amateur in a firm, and is valued because it shows the essential points of the subjects photographed.

Technical Photography. One of the great advantages the technical specialist has over the ordinary all-round worker is a much better and more thorough grasp of the special requirements of his clients. A clever manipulative worker may in many cases deal quite satisfactorily with the photographic difficulties of the work, but it is only by familiarity that the particular demands are met. For instance, a worker accustomed to making outdoor and indoor exposures on a variety of subjects would find little difficulty in focussing and exposing on a locomotive or electric generating plant, but it is quite possible that the resulting picture would be wholly unacceptable to the engineers who had erected or constructed the work. Truly conservative, too many workers would resent criticism, accuse their client of not knowing what he wanted and of not appreciating a good photograph, and, forgetting that not a specimen of photography, but an illustration of some special point was desired, would say such

work was not worth doing. A little more general education and a constant desire to acquire information by observation, together with quickness to apprehend the importance of special instructions, are factors in the successful handling of work of this type. Most important is it to be ready to sacrifice purely photographic conventions and deal with every problem on its merits. We have frequently seen young workers, with minds not set in a cast-iron groove, tackle problems an older hand would have pronounced impossible, and tackle them with very considerable success.

The International Congress of Photography.

A further circular of the programme of the Congress to be held at Liege from July 16 to 25 reaches us from the secretary, M. Ch. Puttemans, and from it we gather the manner in which the week is to be spent. Sunday, July 16, will see the official inauguration of the Congress and of a salon of artistic photography, and for each day of the week a round of visits, functions, and fêtes is arranged, participation in which should acquaint the visitor to the Congress with the industrial and picturesque features of this part of Belgium. Presumably the evenings are devoted to the discussion of the elaborate series of questions which figure on the circular. The Congress proposes to discuss, among other matters, plate speeds, photometry, standards of coloured lights and screens, optical glasses, lenses, shutters, theory and practice of photography, scientific applications and codification of formulae. An ambitious list in truth, and one which might occupy many conventions. Yet we are astonished to find not a single mention of those who are contributing papers or taking part in the proceedings. We should think it was high time that such announcements were made, particularly as a hearty invitation to the Congress is extended to foreigners.

Light-sensitive Diazo Compounds.

Although there are at least three distinct and little-known processes which depend upon the alteration in light of diazo compounds, it cannot be said that the chemical change upon which all are based is at all fully understood. The Feertype, Primulin process, and Diazotype are alike in their dependence on the formation of a phenolic body when a diazo salt is exposed to light, and though the compounds employed are sensitive enough to render the processes fairly rapid ones, no practical use has hitherto been made of them in photography. Some light may be thrown on the complex changes which take place, by experiments in progress in the laboratories of Messrs. K. J. P. Orton, J. E. Coates, and F. Burdett, who have recently made a communication to the Chemical Society. The authors have studied the action of an acid in influencing the conversion of the diazo compound into the phenol by the light, and have examined a number of cases in which the decomposition by light takes place with considerable rapidity. The products of the decomposition may be phenols, ethers (such as anisole or phenetole), or phenylacetates.

Cameras for Telephoto Work.

Rigidity in the camera for telephoto work is a prime necessity, but perhaps every telephotographer does not clearly understand why this should be so. The point cropped up in one of the discussions at the recent Optical Convention, and Mr. Horace Beck remarked that, the nodal points of a telephoto system being so far in front of the lens flange, they were liable to considerable displacement for any

small angular displacement of the lens mount. In other words, stability of the lens board is of much greater importance in the case of a telephoto lens than in that of any other, for a very small amount of "wriggle" will throw the image out of its proper position. The strength and solidity of the front and its constant position at right angles to the baseboard are qualities of the highest importance in a camera for telephotography.

PHOTOGRAPHIC PRINTING PROCESSES.—V. ALBUMEN PAPER.

FOR about forty years albumen paper was, alike by professionals and amateurs, almost the only one employed in the production of photographs, and it is still largely used by the higher-class photographers who issue silver prints. Amongst amateurs and many professionals, particularly those who turn out cheap pictures, it has, during the past few years, been greatly superseded by the gelatine papers. It will, however, be admitted that there is a quality in a good albumen picture that is not surpassed, if equalled by any other glossy paper. The first printing-out paper that was used in photography, as mentioned in the first of these articles, was the plain salted paper, and the difficulty with that in its early days was to keep the image from sinking into the body of the paper, and thus causing the picture to have a more or less muddy appearance, and to lack transparency in the shadows. To obviate this trouble various substances—such as gelatine, Iceland moss, etc.—in small proportions, were added to the salting solution, with the view to filling up the pores of the paper. Amongst the materials employed was albumen, and this led to the introduction of albumenised paper, which, by the way, the user had to albumenise for himself, as at first it was not an article of commerce.

When albumen paper first came into general use it was a very different thing from the albumenised paper of to-day. It was what would now be termed a matt paper for at that period the albumen was largely diluted with water, sometimes with two parts, and at others with only an equal part. When the stereoscope became the rage a demand was made for a paper with a more glossy surface, that would give a better rendering of the finer details in the small pictures. Less water was therefore added to the albumen. Afterwards, when the carte de visite became popular, a still more glossy paper was demanded, and the albumen was then used undiluted, and in some cases it was employed in a somewhat concentrated condition or the paper received a second coating of albumen after the first one had been coagulated. At one period, the manufacture of albumenised paper was an important and lucrative photographic industry in this country, as will be understood when we say that, at about the early sixties the price of unsensitised albumenised paper ranged from twelve to fifteen shillings a quire. During late years, however, the manufacture has mostly drifted to Germany, chiefly to Dresden, and comparatively little is now made in England. But the reader is not so much interested in the history of the albumen paper process as in the working of it.

It may, however, be mentioned that the early albumen paper with a practically matt surface yielded exceedingly fine results of a rich black tone, and we here give a formula for it, as the paper is not now an article of commerce, but is very easy to prepare. This is not the case when one with a highly glossy surface is required, as then considerable experience and knack are required to obtain an even coating, as well as to get the albumen in the right condition.

tion for working. Here is the formula for the albumenising solution:—

Albumen (with the germ carefully removed)...	10 oz.
Water	10 oz.
Chloride of ammonium	200 gr.

This, it will be seen, gives us ten grains of the chloride to the ounce. It will be noticed that this is a much larger proportion of chloride than is employed for modern papers. The mixture is whipped with an egg whisk into a perfect froth, and the membranous shreds allowed to subside, which they will do in ten or a dozen hours. It is a curious thing, and it must be referred to here, that no English paper manufacturer has yet been able to produce a raw paper suitable for albumenising. The whole of the paper used for this purpose throughout the world comes from two, or at most three, factories—those of Kleber Frères, of Rives, and Steinbach, of Malmédy. The former of these is the one that is now most generally employed, and the raw paper may be had from Messrs. Marion and Co., who are agents for its sale. It is supplied of two substances—eight and ten kilos weight to the ream. The one most suitable for our present purpose is the “10 kilo.”

The albumen having been allowed the necessary time to separate from the froth and the flocculent matter to subside, it is strained through fine muslin into a dish. It is then skimmed with a strip of blotting paper if any air bubbles are on the surface. A sheet of the paper is then taken by opposite corners, slightly bent to a curve, and one corner gently laid on the surface of the albumen. The whole sheet is then gently lowered, so as to avoid the formation of air bubbles. It is allowed to rest for a minute or so, then one end is raised and the paper slowly, as it were, *dragged* off, and hung up to dry. When the paper is removed in the way described little or nothing is left on the surface that will drain down and thus produce an uneven coating. The quicker the drying is effected the higher will be the gloss. With slow drying the albumen will sink somewhat deeply into the substance of the paper, which will then have a more matt surface. With the proportion of albumen and water here given the paper will have a semi-glossy surface, but with a larger propor-

tion of water it follows that it will possess a more matt one, and one that is more in accord with those who desire vigorous prints with a more or less matt surface.

The sensitising solution best suited to this paper, and the one which was formerly employed for it, is simply a plain solution of nitrate of silver, 60 grains to the ounce of distilled water. The paper is floated on the solution in the same way as given for the albumen, and allowed to remain for three minutes; it is then fastened by a black pin at a corner to a line, and allowed to dry. After the paper has hung for a short time to drain, the drying may be completed before a fire. This paper, after sensitising, will keep for a couple of days in cool weather, but it is always advisable to use it as soon as possible, as then the whites are purer, and the picture generally is more brilliant than when it has been kept for a day or two. Any of the toning baths which will be given in a future article may be used for this paper, but the one used at the time it was in vogue was a combined toning and fixing one. Here is a formula for one that was very generally employed:—

Water	12 oz.
Hypsulphite of soda	8 oz.
Chloride of gold (dissolved in 2 oz. water) ...	8 gr.
Nitrate of silver (dissolved in 2 oz. water) ...	30 gr.

This makes about a pint of solution. The bath is ready for use after it has stood for ten or twelve hours for the precipitated sulphur to subside. The toning proceeds slowly, and as the bath becomes exhausted of its gold it may take an hour or two; hence there is no fear that the print will be toned before it is thoroughly fixed, as with modern papers and combined baths. Prints produced in the early days of the art by the method here described have proved to be exceedingly stable.

We have here gone pretty fully into this early method of printing on albumen paper, because the results yielded are not surpassed by any modern method where rich black tones are the object in view, and the preparation of the paper involves so little trouble. The next article will deal with the commercial albumen paper as now on the market, and its manipulation.

PAPERS ON PRACTICAL PHOTOGRAPHIC OPTICS.

IV.

The present article on “The Speed of Telephoto Lenses when Employed on Near Objects” concludes a short series of papers dealing with optical questions of importance in practical photography. Those already published (THE BRITISH JOURNAL OF PHOTOGRAPHY, April 28, May 5 and 19) are:—“Focussing Scales and Depth of Field,” by J. H. Taylor; “Lens Calculations Without Arithmetic,” by A. Lockett; “Disks of Confusion and Distances beyond which all Objects are in Focus,” by Rev. T. Perkins, M.A.

TELEPHOTOGRAPHIC optics have generally been treated in a manner which does not commend itself to those who have not gone very deeply into the matter. I propose to deal with my subject by adhering as closely as possible to first principles, and by making no use of formulæ. In carrying out this plan, and with the view of avoiding undue prolixity, I am obliged to assume that my readers are acquainted with the rudiments of the subject.

Telephotographic combinations differ from other lenses in the greater separation between the elements, and also in the method of focussing. In ordinary lens combinations, the Cooke focussing lens excepted, focussing is accomplished by adjusting the distance between the ground glass and the lens. In the telephoto the interval between the two elements is altered. This adjustment alters the equivalent focus. From this it is apparent that the equivalent focus of the telephoto, other things remaining the same, is different from each distance of the object.

The F Value of the Aperture as a Measurement of the Rapidity of a Lens.

The true measure of the rapidity of a lens when photographing any given object is the *cf* value of the aperture; in other words, the back conjugate focus divided by the aperture (effective). In the case of objects at a moderate distance the back conjugate focus approximates sufficiently nearly to the focus of the lens to permit of the substitution of the *f* value in place of the *cf*

value of the aperture. This is the ordinary practice of photographers. For near objects the *c**f* value should always be employed.

All formulæ for conjugate foci are based on the assumption that a pinhole aperture or theoretically thin lens is employed. This very much simplifies the matter; but it is apt to cause trouble in some cases. For instance, if we are working life-size, each of the conjugate foci would be twice *f*, and consequently the distance from the object to the screen should be four times *f*. This would be nearly right if the lens were very thin. But with any compound lens a sharp focus cannot be obtained without sensibly increasing the distance. The correct amount for any lens of large aperture may be ascertained by a simple experiment, provided that you have sufficient length of camera extension. A distinct mark—say, a cross—should be made on a sheet of printed matter, such as newspaper. This is then set up at an angle. The camera is placed with its screen at a distance from the object-mark on the printed sheet exactly equal to four times the focal length. It will now be found impossible to get a really sharp image of the mark on the screen; but the letterpress a little beyond it can be accurately focussed. The distance between the mark and the nearest letterpress which can be sharply focussed is the addendum due to that lens, which should always be added to the calculated distance between the object and screen when enlarging or reducing with that lens.

Ordinary and Telephoto Lenses.

Although this peculiarity exists in all lenses, and ought to be understood, it is not of vital importance in the case of ordinary lenses; but with telephoto lens, on no account can it be neglected.

As an example, I take a lens which I tried some years ago. The positive was 6 in. focus and the negative 3 in. The separation was about 5 in. For distant objects this gave a magnification of $1\frac{1}{2}$ diameters—that is, the equivalent focus would be 9 in., and the back conjugate focus of a distant object would be the same amount. If this lens were focussed on any subject 42 in. from the camera, the magnification would be three diameters and the back conjugate focus 21 in. The ordinary rules would give a back focus of about $12\frac{1}{2}$ in. for a lens of usual form, having a focus of 9 in. under the same conditions. I think that the above shows the utter absurdity of introducing the equivalent focus into telephoto calculations, excepting when dealing with subjects at a very great distance. If you focus by extending the camera the ordinary rules will not apply, and you cannot adjust the distance between the elements without at the same time altering the equivalent focus.

The "Speed" of a Telephoto Lens.

As has been shown above, neglecting minor influences, such as the quality of the glass, number of reflecting surfaces, etc., the speed of any lens depends on two main factors:—

1. The effective aperture.
2. The back conjugate focus when in use.

The proper exposure is proportionate to the square of the back conjugate focus divided by the effective aperture.

Back Conjugate of a Telephoto.

The back conjugate focus, when ordinary lenses are employed on subjects at a distance, approximates to the camera extension. But with a telephoto it very much exceeds this length. The back conjugate focus may be defined as the camera extension required to secure an image of the same size as that given by the telephoto lens, by a pinhole situated in the same plane as the front surface of the lens combination. Perhaps it may be well to remind the reader that the conjugate foci, the object, and the image are in the following proportion:—

Size of object : size of image :: front conjugate focus : back conjugate focus.

How the Telephoto Affects Focal Extension.

The clearest method of dealing with the subject appears to be to illustrate it by an example. For this purpose I have selected one given by Dr. Rudolph on page 14 of his monograph of telephotographic objectives.

The example is that of a full-size image of an object situated 99 in. from the lens. In order to simplify figures I have substituted 100 in. for 99 in. For convenience we will assume that we have an imaginary lens—say, of the stigmatic type—the focus of the front element being 50 in., and that of the whole 25 in. If the front element alone be used, the conjugate foci will be equal to 100 in. each, and therefore the image will be full-size. But the camera extension required would be 100 in.—a highly inconvenient length.

Adding the back element of the stigmatic makes the focus 25 in. A simple calculation will show that with this focus and a front conjugate focus of 100 in. the back conjugate focus will be 33 1-3 in. In the correct position behind the lens we place a suitable negative lens with a screen fixed at a distance of twice its focus behind it. With the screen in this position the negative will magnify the back conjugate focus of the positive lens three diameters, bringing it up to 100 in. as before—that is, equal to the front conjugate focus. Thus, again, we obtain a life-size image. In both cases the conjugate foci are identical, and the aperture remains unaltered. Therefore, the speed will be exactly the same. The only difference will be that the camera extension is reduced to manageable proportions. I have intentionally abstained from giving any value to the negative, because it has no influence on the exposure when the magnification is unaltered. It is a matter to be determined from the focus of the positive, the magnification, and the size of plate to be covered.

The Same Problem Viewed Differently.

If we approach the subject from the standpoint of using an ordinary and a telephoto lens of equal equivalent foci, the results will be less simple.

The equivalent focus of the front element of our imaginary lens remains 50 in., and that of the complete lens 25 in. The latter must be supplemented by a negative and by a screen fixed at its focal plane. This will double the focus of the positive, bringing it up to 50 in., the same as that of the front element. As before, the front element will give a full-size image of an object 100 in. away. The whole positive element will have a back conjugate focus of 33 1-3 in., as we have already seen. Multiplying the back conjugate focus by the magnification—that is, doubling—we obtain 66 2-3 in. Thus, the image will only be two-thirds life-size. (At the same time, the exposure required will be less than one-half.) There are two ways of increasing the image to life-size. We may move the screen back to its original position with regard to the negative, or we may move the lens to a new position 75 in. from the object. Either course involves altering the distance between the positive and negative elements, and consequently an alteration of the equivalent focus. I think that the above will show the utter futility of introducing the equivalent focus calculations except in the case of very distant objects. The proportion between the foci of the positive and negative elements is quite as useless as the equivalent focus, and serves no purpose beyond complicating the matter.

What to Expect from your Telephoto.

It is sometimes claimed that a telephoto gives better perspective than an ordinary lens. This is only true in so far as a telephoto will enable you to increase your working focus. If the distance from the object and the size of the image be the same, the perspective will be the same whether the lens employed be a pinhole, a single glass, a telephoto, or any other lens.

The two important points in which the telephoto differs from other lenses are the variability of focus and short camera extension as compared with the back conjugate focus.

CHAS. LOUIS HETT.

THE WEEK IN HISTORY.

Herschel's Iron Printing.

SIXTY-THREE years ago to-day Sir John Herschel made known to the Royal Society the first iron printing process, named by him "chrysotype." His paper is entitled, "On the Action of the Rays of the Solar Spectrum on Vegetable Colours," and is mostly devoted to the behaviour in light of paper stained with various vegetable juices. "One of the most remarkable results of the enquiry," he proceeds, "has been the discovery of a process by which paper washed over with a solution of ammonio-nitrate of iron, dried, and then washed over with a solution of ferro-sesquianhydride of potassium is rendered capable of receiving with great rapidity a photographic image, which, from being originally faint, and sometimes scarcely perceptible, is immediately called forth on being washed over with a neutral solution of gold. The picture does not at once acquire its full intensity, but darkens with great rapidity up to a certain point when the resulting photograph attains a sharpness and perfection of detail which nothing can surpass. To this process the author applies the name "chrysotype," to recall to mind its analogy with the calotype process of Mr. Talbot, to which, in its general effect, it affords so close a parallel." This process, it will be seen, contains the germ of the platinotype process—i.e., it is the reduction of a noble metal by a photo-produced ferrous salt; but a good deal of water had to pass under the bridges before platinum printing suddenly reached a point at which it assumed practicable and patentable shape. This paper of Herschel's, I may note, does not appear in full in the "Philosophical Transactions" of the Royal Society, but as an abstract on page 393 of the "Proceedings," volume 4.

Iron Printing in 1816.

Sir John Herschel, whose labours in chemical printing are mentioned above, was most certainly unaware of the work of Nicéphore Niepce in the same field twenty-six years previously. On June 16, 1816, in a letter to his brother Claude, Niepce writes of his attempts to devise a photographic process based on the sensitiveness to light of iron salts. "I have read," he says, "that an alcoholic solution of muriate of iron of a full yellow colour becomes white in the sun, and takes again, in the shade, its natural colour. I soaked paper in this solution, and dried it; the part exposed to light became white, whilst the unexposed portion remained yellow. But, as this solution attracted too much moisture from the air, I have no longer used it, as I chanced to come across a much better and simpler substance. A piece of paper covered with oxide of iron, and exposed to oxygenated muriatic acid gas, becomes a beautiful yellow, and bleaches better than the foregoing." Thus it is seen that Niepce conceived the idea, though he failed to carry it out, of applying the iron salts to photographic purposes.

Daguerre's Last Scene-painting.

When Daguerre retired from the photographic business, which he did after being in it for not much more than half a dozen years, he reverted to his old occupation of scenic artistry. The place of his dwelling was the little village of Bry-sur-Marne, outside Paris. At that time there was living there a certain Mlle. de Rigny, a lady who dabbled in the sciences, and who was a sort of patron of Daguerre. At her suggestion, and presumably at her expense also, Daguerre executed a painting for the little church of Bry, which, being placed in an annexe, produced the effect of a considerable chancel behind the altar. On Monday next, exactly sixty-three years will have elapsed since it was formally installed; but it is still there, and anybody who has an hour or two to spare the next time he is Paris cannot spend the time more pleasurably than in taking the electric car to Bry and having a look at it. It has been described as deceptive in the extreme, leading the observer to believe himself in a building twice the size. It is some years now since I last inspected

it, but my recollection is that it was obviously a painting, though an extraordinarily clever one.

The Kennett "Pellicle"—Dried Emulsion in 1874.

Who made the first dry plate? It is a question I would rather not answer, except by saying that the first gelatine plate was not a plate at all, but a dried emulsion which was dissolved in water, and flowed over as many plates as were required.

Those who have been through photography in the days when gelatine was slowly driving collodion from the field, will not need to be reminded that the first step was taken by Dr. Maddox in 1871. Two years later a ready-made emulsion was advertised for sale by Mr. Burgess, of Peckham, but it was soon found that such emulsion would keep only for a very short time, and therefore no use was made of it apart from the fact that the great rapidity of gelatine was not understood in these early days; the plate was grossly over-exposed, and then complained of as foggy and giving no density. There was yet another thing that also conduced to the fogging of the early gelatine plates and their lack of density beyond their being much over-exposed. Photographers, who at first tried them, manipulated them in the same dark room light they had been accustomed to for collodion plates. This was, usually, one sash of a large window covered with a couple of thicknesses of yellow calico, or tannin, and it is now easy to see the effect such a light would have on even a moderately sensitive gelatine plate. However, thirty-one years ago, on Monday next, Mr. Kennett put on the market a dried emulsion, describing the process in THE BRITISH JOURNAL OF PHOTOGRAPHY of June 19, 1874, thus:—"I take the concentrated emulsion, after it has been well washed, from the removable salts, and place it in suitable dishes, evaporating the emulsion till it is of the consistency of thick paste. I then let it cool, and, removing it from the vessels, complete the drying on suitable frames. When dry it can be cut into portions of convenient size, and in this condition is ready for immediate use by simply dissolving in hot water."

I shall have more to say of these early days of gelatine before these notes come to an end. How scanty is the knowledge of many present workers of the gelatine process as to the slow degrees by which photographers have come into possession of their most valuable method. Those who would study the question cannot do better than turn to the article in the Almanac for 1880, in which there is a very clear review of the progress which had been made within about nine years of the inception of the process.

In Memory of Niepce.

I have quoted in these notes rather fully from the letters of Nicéphore Niepce, and I shall quote a good deal more before I reach the end of anniversaries on December 31 next, on which date "Historicus" will remove himself from his weekly place, and be heard no more awaking the echoes of the past. Niepce, even the casual reader of my paragraphs needs not to be told, was the predecessor of all those who have laboured in the photographic field, and that is why I signalise the lateness of any public memorial to him, a delay more extraordinary still in France, where every spare plot of ground is filled with a statue with just about the same avidity once shown by the London County Council in converting every available site into an open space. But it is only twenty years ago on Wednesday next that the statue to Niepce, which stands on the quay in his native Chalon was erected by public subscription. Some ten miles away, in the tiny churchyard of St. Loup de Varennes, he lies buried. His letters to his brother Claude, which contain the chief records of his experiments from about the year 1816, when he commenced his researches, until his brother's death in 1828, are preserved in the little museum, where also the visitor can see the apparatus he employed.

HISTORICS.

THE OPTICAL CONVENTION.

By courtesy of the Papers Committee of the Optical Convention we can now print practically the full text of the discussion arising from certain papers which have already appeared in our pages. The first of these deals with "Aberrations," the subject of two papers communicated on May 31, and printed in our issue of June 2. The general trend of the two papers was towards the classification and

definition of the various aberrations, and in the direction of representing graphically the results of calculations of lens systems and adapting the Hartmann method of testing to permit of measuring and expressing aberrations in the same form. Lord Rayleigh's paper on the "Polishing of Glass Surfaces" is yet to appear, but we hope to give the full text of it, and of the discussions of the remaining papers in our next issue.

ABERRATIONS.

(Discussion of papers read before the Optical Convention, May 31, "The British Journal of Photography," June 2.)

Mr. St. Lawrence Carson: With regard to actual aberrations, there are two ways of looking at the point which, I think, are entirely diverse from one another, and are likely to remain so for some time. The first is the actual calculation of aberrations and the expression of them in numerical form. That leads one to a certain series of results. Von Seidel, I think, got those results in certain cases. For photographic lenses, with which I am concerned, one has to take practice, for the theory is very complicated—if it is a theory at all at present. Taking Von Seidel's results, one gets these five aberrations, and one can calculate the numerical expression for them with a certain amount of labour. Unfortunately, in my own experience, and the experience of most opticians, when you have this calculated expression, if you proceed to construct the lens you will find that even if the two expressions for aberration of the lens are of identical value the performance of the lens may be entirely different, owing, of course, to the point to which Mr. Chalmers alluded—mainly to the distribution of light over the Gauss plane at the image point. That is to say, if you take the actual theoretical Gauss image, the actual point, very few of the rays starting from the object will go through it. You must take a small area to correspond to the object point, and consider that all the rays passing through that small area give you the image. Outside that, of course, there is the scattered patch of light caused by aberration. That patch of light it is that spoils the definition of the lens, and the question, for practical opticians at any rate, is—How is it spoiled? It has always appeared to me that it is spoiled, in the first place, according as this patch is more or less intense; that is to say, you have a certain percentage of loss of light from the actual source. If that is lost, scattered light is concentrated very close to the image—the brilliance of the actual image and of the scattered patch are nearly identical. If it is scattered over a large area, the brilliance of the image is very great compared with the patch, and in actually taking a negative the patch is really invisible except in the case of a long exposure. Roughly speaking, if the brilliancy of the actual image is about seven times as great as that of the aberration patch, caused by all the aberrations, then I think you may say that the lens will give good definition as far as that goes. But there is a further point connected with aberrations which is very much more difficult to calculate, in fact, so far as I am concerned, it has proved practically impossible to calculate, and that is to get a very sharp discontinuity of illumination between the actual image of small area and the aberration patch surrounding it. I have myself constructed a lens which answered to the first condition. It gave a certain amount of aberration for oblique central rays, in which the residual light which did not fall upon the image area was widely distributed: the lens answered the condition that the lost rays should be very much diffused so as to give very weak illumination compared with the small area which formed the actual image. But I constructed this particular lens so that instead of there being a sharp discontinuity from the image to the aberration area there was a gradual falling off, and when you actually examine it with a high-power glass; or, when you take a negative with it, it does not give the definition you expect at first sight. The definition may be all right, but as soon as you enlarge it, even twice, the want of sharpness in the contrast becomes apparent. I believe that is really one root of the difficulty, not only in constructing lenses, but in their performance. I have tried the effect of calculating the total amount of diffused light, and, as nearly as one can, the area over which it has spread, and taking the average amount of diffusion illumination (assuming the diffused light evenly illuminates the aberration area), but it was very unsatisfactory. In some of the aberrations, notably coma, the coma is very concentrated near the image, but the illumination over the average part of the area and discontinuity cannot be calculated. A more accurate calculation or an experimental measurement is necessary. Any test of the numerical value of a performance of a lens must be of value not so much, perhaps, to the optician as to the man who is going to buy the lens; you must give him the assurance that the performance of the lens will give him good definition. Even if you get numerical tests which measure aberrations, it is quite possible that the definition of the lens may be different in two different cases, and until we get round that difficulty, if we ever can, I do not think numerical measurements of aberrations will be of much use from the point of view of the ultimate user of the optical system, although it may be of great use to the optician who is making them. If anything can be done to either devise a practical method of choosing your image

area on the Gauss plane, and then obtaining a discontinuity in the illumination of it and measuring it in practice, I believe that the problem of constructing and testing objectives will be practically solved; but, personally, I do not see at present that there is very much hope of doing it. It is not only that the theory is difficult, the practice, also, is difficult. Although I may take somewhat of a pessimistic attitude, I think the initiation of this discussion by Dr. Drysdale and Mr. Chalmers has been of the greatest value, not only to opticians, but also, I hope, to the users of the results of opticians.

Professor Silvanus Thompson: It is quite clear that the trigonometrical method of following out the individual rays will be more likely to lead to useful results, having measurable quantities which can be specified, than any of the other methods of treating aberrations for this purpose. As Mr. Carson suggests, it is absolutely necessary in dealing with different aberrations to consider the intensity of the light that goes in the different directions. There may, so to speak, be different kinds of aberration in different directions and at different angles, not all equally important in destroying the definition. Dr. Drysdale has not suggested among the tests for aberration some other tests, which, I think, would be quite equally useful to the users of lenses. For example, in testing as to the absorbing properties of the lens, we may imagine two lenses which are quite equal in other respects, in which the glass is so constructed that one will absorb a much larger portion of ultra-violet rays than the other, and they would not be equally satisfactory from the user's point of view—even though their aberrations, strictly so-called, might be exactly alike. With regard to the remark of Dr. Drysdale that the eye, when used in combination with other instruments, cannot be treated always as a portion of a centred system, I suggest that it might be useful in certain instruments to arrange the eye-pieces on them so that they could be swivelled round in some way that you should be able to de-centre the eye-piece so that it might be used, with all the goodness of its central performance, along some oblique direction to receive oblique rays. I am afraid the suggestion is very impracticable from the makers' point of view, but I do not think it is altogether unworthy of consideration. There are a number of cases—they occur occasionally in an isolated form—where some contrivance out of the ordinary run is worth having. It might also be useful to have an eye-piece made, with a fine adjustment—a kind of collar correction—to alter the distance between the field lens and the eye lens, and change the aberrations of the eye-piece for any special piece of work. These suggestions may have some value for individual cases.

Dr. Burton: Professor Thompson's suggestion of a small swivelling movement for an eye-piece is perfectly practicable in certain cases, to give considerable movement. The eye-piece which I have in my mind was used for a focussing screen. The focussing screen was a transparent one, with scratches upon it, so that the eye-piece formed part of the system with an enlarging photographic lens. The instrument was for enlarging stellar spectrograms, and it was necessary to run from end to end of the focussing screen to see that there was good definition in every part. If that eye-piece was merely made to slide laterally it received no light whatever in the out-lying parts of the field. It was so constructed that it could swivel about an axis lying in the focal plane, so that it was made to bring any part of the focussing screen being used into the view of the eye-piece.

Mr. D. E. Benson: I would like to suggest, more from the purchaser's than from the manufacturer's point of view, that an addition should be made to Dr. Drysdale's specification—at any rate, in regard to photographic lenses—and that is, that he should give us some idea of the amount of flare the lens possesses—I do not mean the flare that arises from what might be called coma, but the flare that arises from the internal reflection in the lens. I have had through my hands lenses which the makers assured me gave absolutely critical definition; but if you get a small bright light on the one side and a small dark shadow on the other, your plates are ruined by the internal reflection.

Dr. C. V. Drysdale, in reply, said: Although the discussion has been most interesting, I am perhaps a little disappointed that we have not had many expressions of opinion as to whether there was any possibility of a consensus of opinion on these definitions: but doubtless that will take a long time, and, of course, I am perfectly well aware that many who are best competent to deal with the question are those who feel that time must be given to it. I think it is

a thing we may well keep in mind—whether it would not be advisable, having got to the stage we have, for this convention to appoint a committee to study this question during the forthcoming year, and to report on it to the next meeting, which we hope will take place next year. I cannot help feeling that the matter is of such extreme importance that, in our present state of information, we might try to do what we can. Mr. Carson has brought up the very important question as to the size of the diffusion patch, and has pointed out that our criterion as to focus and definition must deal with the distribution of the light. Mr. Chalmers has pointed out the same thing. But I am afraid that, although that is the case, it does not convince me quite of the difficulty of making the tests. These difficulties of diffusion are, to a certain extent, due to the aberrations of higher orders as well as aberrations of the first order. It appears to me that if we make our tests on the basis I have suggested, at different apertures, that we shall then know the distribution of the light. It is perfectly clear that the distribution of light is a question, to a certain extent, of aperture. If we stop down our lens to a very small aperture, then there is not much chance for the light to diffuse; as we open up, the size of the diffused patch gets greater and greater. If we compare the size of the aberration patch with the size of the aperture, or use two apertures, I think we come to something like a knowledge of the distribution of light in the way Mr. Carson suggested. I know there are practical difficulties, but I do not think they are insurmountable. I certainly do not think there is any theoretical difficulty or practical impossibility of getting this distribution of light in the focus. In view of the extreme importance of the Hartmann method of testing, does Mr. Chalmers

think the very imperfect suggestion I have made of actually visually examining the position of the central diffraction rings for different positions of an aperture in front of the lens would enable us to get that information? Dr. Thompson raised the question of the quantity of light transmitted both for visual and for ultra-violet light. In the paper he will see that I have said—“there should also be stated the maximum illumination for visual or actinic light.” That is so extremely important that I should have been very sorry to have omitted it.

Mr. S. D. Chalmers: In reply to Dr. Drysdale's suggestion, the only drawback to the method mentioned is that it requires very perfect apparatus, because the measurements are not made at the same time; and any slight want of adjustment or want of stability in the apparatus will tend to throw out the measurement, and cause errors to arise. Therefore it is desirable to make all the exposures or measurements for one point at the same time.

The President: In asking you to thank Dr. Drysdale and Mr. Chalmers for their papers, I should like to make one remark with regard to the definitions of aberrations that have been offered. Viewed from the standpoint from which they have been put before us, they are no doubt admirable. At the same time, I think it is of great importance that definitions of aberrations which are adopted should be such as are strictly capable of measurement; and I feel some little doubt myself, after a slight experience in testing lenses, as to whether definitions that depend on determining as accurately as one can the size and position of a patch of light are those which will be found best for specifying numerically the performance of the lens.

THE PRINCIPLES OF TRICHROMATIC PHOTOGRAPHY.

(Discussion of the paper by A. J. Bull before the Optical Convention on June 2, and printed in “The British Journal of Photography,” June 9.)

Dr. Clay considered that Mr. Bull was working on the right lines in endeavouring to reproduce colours of different degrees of brightness; that it was of the utmost importance to reproduce the same colour in the same way under different conditions of illumination, even if this necessitated the less perfect rendering of an evenly illuminated spectrum. Our aim is to reproduce natural colours, which consist of large broad bands of mixed colours, which may be very unevenly illuminated. There can be no doubt that plates do not follow a straight line law, hence a theoretically perfect rendering at one luminosity might be very far out at another, and it is this very difficulty that Mr. Bull is attacking so successfully. He suggested the use of a spectrum from a wide slit as a more satisfactory source of mixed colours than a colour chart.

Mr. A. C. Jolley: One cannot pass without comment the beautiful and convincing demonstrations which Mr. Bull has devised to illustrate his points. The question of filter records intended to follow curves and those having abrupt absorptions was fully discussed in our joint paper of 1904; and experience only tends to strengthen the facts therein stated. No matter how tempting filter records following mixture curves may be in theory, the fact that they will in practice work only at one critical exposure condemns them, since in one subject one may have considerable range of light and shade. It would undoubtedly seem, therefore, that filter records which constitute even bands terminating abruptly between prescribed limits, and

whose overlaps in the yellow and blue green are restricted to a region whose component wave-lengths are to constitute the printing colours, will more truly reproduce a subject with considerable range of light and shade than filters whose records possess definite maxima; and there is but little doubt that the correct regulation of this overlap is one of the most important factors in the successful application of the process.

Mr. Dowse: Changes in hue, consequent upon variation in luminosity or illumination, may be demonstrated by the following simple experiment. Arrange two white surfaces, such as small filter papers, in such a position that they are close together, but unequally illuminated by some source of light. If these surfaces be observed through coloured glass from a distance of a few feet, a difference in colour will be manifest. When the more illuminated surface appears yellow, the other surface has an orange tint; if the former be violet the darker surface becomes bluer in tint. A degradation with the colour nearer the red end of the spectrum seems to take place when the illumination becomes less. Mr. Bull has also pointed out that in examining the spectrum of an arc lamp the sodium D-line, which is always present, appears bright yellow on an orange ground.

Dr. Drysdale referred in appreciative terms to Mr. Bull's work. He was glad to see a general recognition of the necessity for reproduction colours consisting of bright bands.

REMINISCENCES OF THE DUBLIN CONVENTION OF 1894.

II.

Phoenix Park.

I must not forget another incident which happened on a certain evening. Four members met opposite the Bank of Ireland, viz., in front of that historical building Trinity College (where our meetings will take place this year), and decided to go for a drive to Phoenix Park—one of the most extensive and beautiful in the world. It consists of 1,760 acres, and is kept in excellent condition. A good nag was selected, and off we started. The drive was most enjoyable, and the various objects of interest were pointed out by our coachman: the Viceregal Lodge, the Wellington Pillar, the Military Hospital, the Phoenix Column, etc.; but, curiously enough, the spot we were particularly anxious to see was missed. I allude to the scene of that terrible tragedy of 1882. When asked about it, our charioteer said we had passed it. We insisted upon going back. I had often heard that the car drivers evaded the spot if possible; perhaps out of shame—let us hope so. Yes, there was the place, with the turf in the path scored away in the shape of a cross, showing where two defenceless and honourable gentlemen had been

cruelly murdered. Ah, well! That happened more than twenty years ago—“Let bygones be bygones.”

Rain and “Precautionary Measures.”

But to our tale. It came on to rain, and one of our party, a particularly nervous gentleman, was unprovided with either a mackintosh or umbrella. We sheltered him as best we could, but he was so anxious not to catch cold that we asked the javey if he knew where we could get a drop of good whisky. “A' right, Sorr,” said he, and drove to the other side of the park at a furious rate. There, under some trees, he suddenly pulled up, and we descended; so did the rain.

I don't think I should know the house again, but I am quite certain I should know the flavour of the whisky. I never tasted anything like it before—nor since.

I may here remark, incidentally, that only one of our party really wanted any whisky, but it does not do to be unsociable at such times; and the other three of us allowed ourselves to be persuaded to take a little, as a precautionary measure.

"Ye'll get a dhrop of the *raal* potheen here, gintlemen," said he. The *raal* potheen, thought I, and my mind wandered back to Bellamy's old song, one verse of which runs:—

Don't go dhrinkin' of brandy, or hollands, or shrub,

Or gin—them's all doctored, depind av it—

Or ye'll soon have a nose that ye never can rub

For the blossoms that grow at the end av it.

But the *raal* potheen, it's a babby may take

Before its long clothes are cut shorter,

As much as would shwim it, an' divil an ache,

Av its not mixed with too much could water.

I prepared, therefore, for a surprise, and I had it. Would we like it old? Yes. Now there is whisky *and* whisky. What's in a name? as somebody says somewhere—"That which we call a nose, by any other name would smell as much." Many of us have seen two or three brands of liquor served from the same bottle; but this was the *raal* potheen—and *old*.

I suppose I am no judge of potheen, but if what we had was old I should think the new might be useful to clean paint, or, adulterated with beeswax or shellac, would make good furniture polish. To say it went down like a torchlight procession would be to "damn it with faint praise"; however, our timid friend did not catch cold, so it answered its purpose. Potheen is evidently an acquired taste, unless you are born with it; probably that was the case with our jarvey.

Sights of Dublin.

Monday.—During the Sunday there had been many arrivals, but it was not until Monday morning we realised that this was to be a record meeting. The rooms at Dawson Street were crowded, and the Hon Secs. (Messrs. Cembrano and Ruthven) were working "like niggers," or more so. Everybody was being introduced to everybody else; there was a pleasant chinking of money; the pages of the signature book were being rapidly filled up; members (as usual) were clamouring for information which was plainly printed in the handbooks, and every one seemed in the best possible health and spirits. Some, with cameras, hastily signed the book, and then quietly went off to secure pictures of some of the attractive bits previously noted. Then parties were made up to see the sights of the city, and little batches of members started in various directions; the largest parties appeared to be commencing at the Cathedral and finishing at Guinness's Brewery—one of the most interesting things in Dublin.

I should think that during Monday more snapshots were taken in and around Dublin than at any previous period in its history. All the members appeared to be making good use of their time, and seemed desperate in their desire to benefit the plate makers as much as possible. The statuary seemed to attract an enormous amount of attention. There is a great deal of it in Dublin, and, as a whole, it is very effective. Of course, Foley's grand monument to O'Connell is the "pick of the basket," and I am inclined to think that Tom Moore's is about the worst; it is quite unworthy of Ireland's charming poet, who has got no end of people into trouble through writing:

"When we're far away from the lips we love
We have but to make love to the lips we are near."

The suburbs of Dublin, too, came in for their share of the camera—Glasnevin Cemetery, with its fine monuments; the People's Garden; the Zoo, with its lake and shady walks; Kingstown, its East pier and mail boats; the Hill of Howth, with its fine view of Dublin Bay; and many other attractive spots within easy distance.

As for Sackville Street, the Nelson Pillar, the Post Office, the Bank of Ireland, Trinity College with its statues of Oliver Goldsmith and Edmund Burke, and its bell tower, and the O'Connell Bridge, all day long some one seemed to be immortalising one or other of them, and more than one energetic member even strayed as far as Morrison's Hotel (now demolished) in order to photograph the fire-escape down which, a short time previously, a prominent member of Parliament descended, on being surprised paying an amatory visit to a lady well known in Irish society.

However, the longest photographic day must have an end, and as evening drew near numbers of ladies and gentlemen wended their way to the Royal Dublin Society's buildings in Kildare Street, where the official reception took place. First, the official business—Mr. Andrew Pringle in the chair. The Lord Mayor welcomed the members, Sir Howard Grubb gave us an excellent address, and then came the conversation in the magnificent museum. It was a large and influential gathering which met to do honour to the members of Convention, and the electric light and the fine band of the Royal Irish Constabulary added to the brilliancy of the occasion. There was a lantern show, by-the-bye, in a side room. This consisted mainly of slides from negatives taken at previous Convention meetings, and some of the subjects, the portraits especially, seemed particularly puzzling to the uninitiated.

F. A. BRIDGE.

(To be concluded next week.)

FOREIGN NOTES AND NEWS.

A New Derivative of Amidol.

M. REEB, about a year ago, in a paper before the Société Française, suggested the use of amidol in a solution of sodium bisulphite, which was neutralised by the addition of small and increasing quantities of sodium carbonate, but it was found that all plates would not give satisfactory results, in many cases dichroic fog resulting. He has now discovered that the addition of small quantities of pyrocatechine and hydroquinone to the amidol entirely prevents this fog, and that the new compound, which he calls "amidol salifié," will develop in an acid bisulphite solution without any sulphite of soda, but the total time of development is about eighteen hours. The formulæ he gives are as follows:—

Bisulphite Solution.

Sodium sulphite	180 grammes.
Water	800 ccs.

Dissolve by the aid of heat, and add:—

Sulphuric acid	20 ccs.
Water	200 ccs.

Amidol Salifié.

Amidol	2 grammes.
Pyrocatechine	1 gramme.
Hydroquinone	1 gramme.

The actual developer is:—

Amidol salifié	2 grammes.
Bisulphite solution	50 ccs.
Water	100 ccs.

This takes about eighteen hours in all, but by successive additions of 25 ccs. of a 20 per cent. solution of carbonate of soda development is hastened, and the maximum rapidity is obtained when the bisulphite is converted into the neutral sulphite, so that the above bisulphite can be replaced by nine grammes of neutral sodium sulphite, and the same result obtained. One advantage of the new developer is that the solutions keep well.

Canada Balsam in Collodio-chloride Emulsions.

Herr Benzen suggests as a substitute for glycerine and castor oil in collodio-chloride printing-out emulsions the use of Canada balsam, which he states has none of the disadvantages of the

mixture. Contrary to the generally accepted statement that a balsam is entirely soluble in ether, the author states that only partly so, and the insoluble portion should be removed. Parts of Canada balsam should be mixed with fifty parts of the solution filtered and the filtrate placed, in a dish, in

a place free from dust to evaporate. Forty parts of this purified balsam should be dissolved in 460 parts of ether, and 5 per cent. of this added to the emulsion; though for highly glazed papers a little more may be used and less for the matt. The balsam solution should be added to the emulsion after all the other ingredients.

ON THE REPRESENTATION OF MOVEMENT BY ART AND BY PHOTOGRAPHY.

I.

portrayal of motion has long been a task that has concerned artists and photographers. The endeavours of the latter to give an accurate representation of a moving object but to convey the idea that it is in motion have been too often handicapped by the limitations of both the apparatus and the photographer. John Bartlett, a well-known authority on photographic artistic matters in the United States, has written a beautiful article on the subject in a recent number of "Camera" and we think it is of sufficient interest to reproduce in part. Bartlett says:—

The Eye v. the Lens.

The delineation of the forms of Nature the human eye, aided by the most delicate touch, cannot approach the accuracy of the pencil of light, and photography has therefore, directly or indirectly, to a perception of many of Nature's beauties and many of her appearances which the unassisted eye might not recognise as beauties but for the camera's searching eye; yet, from the tribunal of art, judgment must often be pronounced against photography, and the 'book of law' is the conditions imposed by the limitation of our vision. Upon the physiological accuracy of the eye, not to see Nature as she actually exists, its imperfection, as compared with the lens of glass, depends our pleasure in pictures.

Persistence of Vision.

How often do we hear it said: 'A photograph cannot lie'—like Macbeth's witches, it sometimes 'lies like truth.' A representation of Nature, to be true artistically, must be true in the values of light and shade as well as true in drawing, but in the tone the photograph is frequently incorrect. The variety of effects of colour in objects, and the effects produced by reflection and interpenetration of colours, are heightened or modified by perception of vision, and as this impression cannot be reproduced upon sensitive film, even with the employment of orthochromatic plates, the photograph fails to reproduce what the trained eye of the painter sees and transfers to his canvas. Now, still further, it has frequently been demonstrated that the image impressed upon the retina remains there an appreciable space of time. It is not instantaneously formed and then instantaneously obliterated, but its transit allows the superposition of other impressions. It is this peculiarity of vision which enables us to enjoy the so-called 'persistence of vision' and other optical wonders.

Arrested Motion False.

We compel the painter to represent arrested motion, an actual instantaneous attitude, because he has the presentation of a single instant of time, would be as wise as to confine him to the use of colours which do not modify each other harmoniously when in motion, though science proves the isolated existence of primary colours in the spectrum. Objects, though passing continuously through an unbroken series, seem to the eye to have no break in succession, hence our impression of progression, but instan-

taneous photography (that is, photographic impressions of fractions of a second) by isolating any special movement in the series, really destroys all conception of motion. Therefore the reason why the painter of movement never seriously regarded the investigations of Muybridge and others who showed the actual truth of Nature

Art Governed by Visual Laws.

We do find frequent examples in the history of art conformable to the scientific demonstrations; but from the fact that the painters selected only certain phases of rapid movement, we are justified in claiming that they were conscious that art is governed by visual laws which demand a different treatment, and that taste tolerates conventionalities rather than radical representations. When we come to consider moving objects we find plenty of contradiction between what appears to be and what is. Driving clouds or a ship in full sail are easily photographed or drawn, simply because, although moving rapidly, their form varies very little as they proceed, and their apparent form is in no way different from their true form. Even the ever-heaving waves of the sea, though offering peculiar difficulty to the painter, on account of the rapidity of movement, are often correctly drawn: indeed, often more true to moving nature than the petrified presentation of photographic impressions of a thousandth of a second.

Photography Sometimes Helpful to Art.

We cannot, after what we have just said, be accused of partiality to photographic art. We have pointed out its limitations, and perhaps ruthlessly shown its shortcomings in art, but let us say every painter must candidly acknowledge the great service photography has rendered him by treasuring up those transient shapes of sea beauty which his pencil despairs of recording. The Old Masters, even the Venetians, who lived upon the very bosom of the sea, give us but crude representations of the sea. It was left to modern art—we might almost say to contemporary art—to study the volume of the moving waters for its own beauty independent of its association as a conventional background for human motives. Turner and others come very near Nature. They give us the impression of mass and volubility, of transparency and mobility. They show us admirably the lapping and curling of the waves with their lace-like traceries, the intermingling of light and shade, broken up by the little surges and ripples; yet, in all probability, it was not so much their quickness of perception as the revelation of sea movement by the camera. Understand we are not maintaining that all photographs of sea action represent artistic movement. Many present but a petrification, the result, we are inclined to believe, of using a too rapid shutter.

Position Assists Idea of Movement.

But let us return to the discussion of our dictum, that it is not the business of the pictorial photographer to photograph moving objects contrary to our visual impression. There are plenty of artistically true positions, which a moving figure takes for our selection, possible with the use of a slow shutter. Let us suppose an

example: We have two men walking, one of whom has his left leg forward, and the other his right leg. They are going fair heel-and-toe, perhaps not very elegantly, but at any rate it conveys the idea of walking. Now it is self-evident that in walking the legs must pass each other at every step. Let us endeavour to draw or photograph our pedestrian at the moment when one leg is passing in front of the other, and we shall find it impossible to give the idea of fair heel-and-toe walking. Now, why is this? The reasons are twofold; in the first place, at each step there is a momentary pause when both feet are on the ground, and the eye seizes on this pause and naturally associates the position the legs are in with the action of walking. Secondly, it is only in this position that any idea can be given of the length of the step and the rate of the man's progress. A photograph taken at the moment when one leg is passing the other would not convey the impression of forward movement. In nature it is the actual motion of the legs which causes the attitude to appear all right, but if we could arrest it instantaneously the action would appear as cramped in nature as it would in a photographic portrayal. During a thunderstorm at night, if you should ever happen to see a walking or a running man illumined by the flash of lightning, you will notice that he does not appear to be moving at all unless the flash should happen to occur just at the time when his legs are fully extended. The attitude appears always more or less cramped, unless the moment is seized when the runner's legs are fully extended.

Galloping Horses.

The old-fashioned way of representing a horse galloping, the hind legs invariably on the ground and the fore legs well bent (as old, anyhow, as the Assyrian sculptures), was blindly adopted by successive generations of artists up to the early part of the nineteenth century. Vernet was the first to innovate. His studies of horses in motion are superb, the action is always spirited, yet true to nature. His method has never been improved upon, though one occasionally sees a photograph of a moving horse which reminds him of his pictures. Vernet had quick visual perception and artistic selective ability. One would think, too, that Michael Angelo's eye had a sort of photographic shutter attached, so close do his moving figures approximate finely selected snapshot pictures.

Sixteenth Century Painters Worth Studying.

Charles Leslie has called attention to a peculiar conception of Angelo's 'Judith and Holofernes.' The headless man turns on his couch, and the rustling of the curtains, occasioned by the up-raised and moving arm, causes Judith, who is about to escape, to look back. Thus the terror of the scene is indescribably heightened by an attention to the fact of the continuation of muscular movement for a short time after decapitation. The reeling 'Bacchus' of Michael Angelo's is another striking example of the visual perception of this great genius. The sixteenth century painters and sculptors ought to be studied by every photographer in search of pictorial movement. Their work is simple, natural, and true. Andrea del Sarto's 'Madonna della Arpie,' standing so firmly and strongly on her feet, gives us the impression that she is really able to carry the heavy boy on one arm. The way in which she has propped the book against the thigh and rests her hand on the edge, so that a large and coherent design is formed, is a magnificent example of the way in which these sixteenth century painters show life, force, and energy.

Other Examples.

We want to show the great advance in the representation of spontaneity of movement of the sixteenth century painters over those of the previous century. True, the fifteenth century enjoyed the

highest degree of charming movement in the light-footed figures that speed across its pictures. This motive was used with good reason by every artist. In the picture by Ghirlandajo of the 'Birth of John the Baptist' we observe the angel with the candle approaching swiftly, and the servant, who brings fruit and wine, coming bursting into the room, her drapery blown out by the breeze. You will note the position of the feet, giving admirably the heel-and-toe movement referred to above. This representation of movement, so characteristic of the age, finds its sixteenth century counterpart in the picture by Raphael of the fire in the Borgia Palace (Incendio del Borgo). The whole difference in the idea of form lies in the contrast between these two figures. This woman engaged in carrying water, who supports her burden with stalwart arms as she walks quietly erect, is one of those magnificent creations of Raphael's mature and manly sense of beauty. It may not be fair to say so, but it was in the sixteenth century that Baptista Porta discovered the 'camera obscura'; Raphael and Angelo may, after all, have put their heads under the focussing cloth. In Raphael's picture of the Transfiguration we shall notice how quick an eye the great painter possessed. The rapidity and suddenness of movement on the part of the mother of the demoniac boy, whom the Saviour has just healed, is such that the draperies have not had time to follow the impulse of the body. She alone has turned. Her girdle left behind by her movement seems to be placed awry, but we soon perceive that if she were to return to her former attitude, it would be in its proper place.

Limitations of Painting.

Lessing, the great German critic, tells us:—

'All appearances of nature which in their actual state are but of an instant's duration—which can be what they are but for a moment—all such appearances, be they pleasing or be they horrible, received through the prolonged existence which art gives them a character so contrary to nature that at every repeated view we take of them the impression becomes weaker and weaker, till at last we turn from the contemplation in weariness and disgust.'

Le Mettrie, who had himself painted as Democritus, the laughing philosopher, laughs only at the first time we look at the picture. Look at him often, and the philosopher is converted into a buffoon and his laugh into a grimace. We all feel how disagreeable an unmeaning laugh is, and in a portrait, unconnected with story of incident, it becomes unmeaning or worse, especially when the face is made to look at us.

Leave Something to the Imagination.

In the wonderful antique group of 'The Laocöon' the father and his sons are being crushed to death by huge serpents, but the sculptor does not seek to represent in the countenances of the sufferers the distortion which actually accompanies the physical and mental anguish, but the spirit of a great self-collected soul is portrayed. The beholder is rather led to the contemplation of the extreme expected, while he does not actually see it—and so the true end of all art is accomplished by leaving something to the softening influence of the imagination. The emotion of the horrible is eliminated by the presentation of a phase, which is not disappearing by its continuation in art.

In other words, that which is beautiful in a work of art is beautiful, not to the vision as a single isolated phase of a continuous action made for ever unchangeable, but as it is suggestive of succeeding phases, stimulating the imagination to create for itself something which is not actually presented to the eyes, but effected, nevertheless, by their means. The mind thus anticipates, carries itself beyond what could have been actually represented at the precise moment the scene depicts, and its delight is thereby intensely increased.

DEVELOPMENT NOTES.

THE old theory that errors in exposure can be compensated for by tinkering with the developer after it has been applied to the plate still holds good in some quarters, and there are few who are still firmly convinced that if they do not carefully watch the plate during development and look through it at least half-a-dozen times during development, it will turn out a failure. What particular virtues accrues to the plate from looking at it I have not been able to discover. It certainly may happen that it will be fogged by the dark room light, and if pyro-soda be used it can certainly be more deeply stained than would otherwise be the case.

In my early days I admit that I was probably as big a sinner as anyone else in respect of these two points, but a series of personal experiments with Mr. Watkin's system of "time" or "factorial" development proved to my satisfaction the utter fallaciousness of hooking the plate out of the dish every minute to see how it was going on. I found that I could obtain a far more even set of negatives from varying exposures by use of the factor than I could by judging density in the old way.

I found, too, that there was an immense amount of saving, both in time and trouble, for a great deal of my work is developing amateur's negatives, which, as all the world knows, receive vastly varying exposures, some of which may be correct, but of which the majority certainly are not. Examination of the plate during development meant practically developing each plate by itself, but now I can put six quarter plates in a dish and flood them with the developer, and using a pencil and paper to note down the time of appearance of the image, have only to do a simple sum to find the exact time that each one must remain in to obtain the best result.

Quite recently, however, I had a very large number of negatives to develop, which would have entailed many hours of work, and just at a time when I could ill spare it, so I determined to give stand

development a trial, and after the first six plates had been thus developed the whole of the batch were treated the same, with surprisingly satisfactory results, for not a single negative was lost, though, judging from the varying times they took, they must have received the most extraordinary exposures.

The particular formula I used was:

Ortol	10 grains.
Potassium metabisulphite ..	5 grains.
Sodium sulphite	65 grains.
Sodium carbonate	65 grains.
Water	20 ounces.

A dozen plates were placed in the tank and left for a quarter of an hour before being looked at, and they were all finished in less than half an hour, and by using two tanks the large order was soon wiped out, and not a single one was spoilt.

Whether stand development is any improvement on the factorial system for studio work I am unable to say; probably it would be found to be hardly worth while, for there is never such a rush, and then it may not be possible, of course, to obtain tanks for larger negatives, but for quarter plates, particularly when they have received all sorts of exposure, I am convinced it is superior to all other methods. The fineness of grain of the negatives is excellent, they possess good gradation, and no trace of fog from development or stain. I believe almost any other developer but pyro may be used for stand development, with equally satisfactory results.

Theoretically, if Messrs. Hurter and Driffield are right in their contention that one developer will not bring out more than another and the action of light on the plate is absolute, it seems quite reasonable to suppose that a very weak developer may act quite as well as a stronger one provided sufficient time is allowed.

T. C. GRAYDON.

AN APPEAL TO CHARITY.

The Mawdsley Fund.

A FURTHER response to our appeal of June 2 takes the form of the list published below, which represents the further remittances received up to Wednesday morning last. In acknowledging the generosity of the donors, we would say that the total now reached by the fund justifies us in making a regular allowance to Mr. Mawdsley of an amount, which, though not great, will place him in a state of comparative comfort, and will relieve his mind of an anxiety as to how his few wants are to be provided for.

FORTHCOMING EXHIBITIONS.

July 4 to August 12.—Northern Photographic Exhibition. Secretary, F. G. Issot, 62, Compton Road, Harehills, Leeds.

July 15-25.—Sixth International Salon Association Belge de Photographie, Liège. Secretary, Mr. Servais, 34, Rue du Saint-Esprit, Liège.

August 7.—Andover. Hon. Secretary, W. I. Gradidge, Jubilee House, Andover.

September.—Royal Photographic Society, New Gallery, Regent Street, London, W. Secretary, J. McIntosh, 66, Russell Square, London, W.C.

October 28-November 4.—Sheffield Photographic Society. Joint Hon. Secretaries, J. W. Charlesworth, 1 Joshua Road, Sheffield, and James W. Wright, 62, Vale Road, Sheffield.

November 14, 15, 16.—Ipswich Camera Club. Hon. Sec., R. H. Sutton, 37, Henley Road, Ipswich.

November 21-25.—Southampton Camera Club. Hon. Secretary, S. G. Kimber, Oakdene, Highfield, Southampton.

December 1-6.—Hove Camera Club. Hon. Secretary, A. R. Sargeant, 55, The Drive, Hove.

December 12-20.—Southsea Photographic Society. Hon. Secretary, F. J. Lawton, 5, Pembroke Road, Portsmouth.

March 3-10, 1906.—South London Photographic Society. Hon. Sec., H. Creighton Beckett, 44, Edith Road, Peckham, S.E.

March 6-20, 1906.—Glasgow Southern Photographic Association. Hon. secretary, William H. Frame, 28, Bank Street, Hillhead, Glasgow.

FORTHCOMING COMPETITIONS.

July 15.—Warwick. Money prizes for members of photographic societies for pictures taken on Warwick Dry Plates. Warwick Dry Plate Company, Warwick.

September.—Kodak. £400 in prizes for results on Kodak products. Kodak Ltd., 57-61, Clerkenwell Road, London, E.C.

October 1.—Thornton-Pickard. £100 in prizes for photographs taken with Thornton-Pickard cameras or shutters.

PHOTOGRAPHIC EMPLOYEES IN NEW SOUTH WALES.

The first annual meeting of the Photographic Employees' Association of New South Wales was held in the Queen's Hall, Pitt Street, Sydney, during the last week in February. The vice-president, Mr. H. Bradley, occupied the chair.

The Secretary, in presenting the annual report, congratulated the members in being able to report that the past year had been most successful, as the Association started with fifteen members, and had increased to such an extent that the number on the roll now was nearly 100, and the financial statement showed a very good balance in hand.

The election of officers resulted as follows:—President, Mr. J. C. Cruden (re-elected unopposed); vice-president, Mr. H. Bradley (re-elected unopposed); secretary, Mr. Walter Davies (re-elected unopposed); assistant secretary, Mr. J. Stuart, Jun. (unopposed); treasurer, Mr. A. Morrison (re-elected unopposed).

A special vote of thanks was accorded the secretary for the efficient manner in which he had carried out the business of the Association during the past year. He was granted six months' leave of absence, in consequence of his leaving Sydney this week on an extended trip to Europe. The assistant secretary was empowered to carry on all the duties of the secretary, also to represent the Association in the Arbitration Court.

Photo-Mechanical Notes.

Increasing the Sensitiveness of Bichromated Fish-glue and Albumen.

In the current number of "Le Procédé" MM. Calmels and Clerc give the results of their experiments of adding dyes to the bichromated albumen and gelatine as used for the half-tone process. The particular formulæ they employed were—

Water	1,900 ccs.
Enamel glue	1,000 ccs.
Cologne glue	50 gms.
Ammonium bichromate	60 gms.
Ammonia	10 ccs.

and—

Water	1,000 ccs.
Albumen	100 ccs.
Ammonium bichromate	15 gms.
Fish-glue	20 ccs.

At a fixed distance from an arc-lamp of low amperage the exposure for these was forty and twenty minutes respectively. Erythrosine BE, and RE of the Société des Matières Colorantes de Saint-Denis, were tried, and the former was found to be superior. In the case of the enamel process it was found that the addition of 0.1 per cent. of the erythrosine BE reduced the exposure to one-half—that is to say, to 20 minutes; with 0.2 per cent. this was reduced to fifteen minutes, but increase beyond this quantity apparently destroyed the sensitiveness. The increase in sensitiveness was not proportional to the increase of the dye, but, as in the case of an emulsion of the silver haloids, an excessive quantity reduced the general sensitiveness. With the albumen 0.2 per cent. of erythrosine BE, the exposure was reduced to one-half, and with 0.4 per cent. to six minutes; but with 0.8 per cent. there was again apparently no sensitiveness. To obtain the same results with

albumen as with the fish-glue the amount of dye should be doubled; but, although with the enamel the image became the more perfect the more the exposure was reduced by the increase of the dye, with albumen the image had a marked tendency to become flat, and to lose more and more the ratio of its values. From the practical point of view, therefore, the use of erythrosine in the albumen process cannot be recommended for negatives "au trait," i.e., line-work.

Eosine VE and JE, by the same makers, were also tried, but the former proved the more satisfactory. With fish-glue 0.2 per cent. reduced the exposure to seventeen minutes, 0.4 per cent. reduced it to ten minutes—that is, one-fourth of the original exposure; 0.8 per cent. destroyed the sensitiveness. With albumen alone—that is, without the fish-glue—0.4 per cent. of eosine VE reduced the exposure from ten to five minutes. Acridine orange NO (Leonhardt), and various ethyl and methyl violets showed no action; whilst bleu carmine V (Meister Lucius and Bruning) and bleu diamine pur (Casella) were active, but inferior to the above-mentioned erythrosine and eosine.

Etching Steel.

A correspondent of the "Inland Printer" gives the following method of marking steel tools as that adopted by a large house in the trade:—"We first have a rubber stamp made with white letters on a black ground, then we make up an ink to use with this stamp as follows:

Ordinary resin	½ pound
Lard oil	1 tablespoonful
Lampblack	2 tablespoonfuls
Turpentine	2 tablespoonfuls

Melt the resin and stir in the other ingredients in the order given. When the ink is cold it should look like ordinary printers' ink. Spread a little of this ink over the pad and ink the rubber stamp as usual, and press it on the clean steel—saw blade, for instance. Have a rope of soft putty, and make a border of putty around the stamped design as close up to the lettering as possible, so that no portion of the steel inside the ring of putty is exposed but the lettering. Then pour into the putty ring the etching mixture, composed of 1 oz. of nitric acid, 1 oz. of muriatic acid, and 12 oz. of water. Allow it to rest for only a minute, draw off the acid with a glass or rubber syringe, and soak up the last trace of acid with a moist sponge. Take off the putty, and wipe off the design with potash solution first, and then with turpentine, and the job is done."

Callitype.

A copy of the "Hammond Herald," Vol. 1, No. 1, lately received, marks a new departure in trade (?) journalism. All the type matter was written on a Hammond typewriter, within a given number of spaces and with a black ribbon, after which this copy was photo-engraved and arranged in forms for the press.

Naturally, it looks "typewritery," but it is not displeasing, and is quite neat. We shall be interested in seeing future copies.

The editor is Mr. Jacob Backes, who devised the peculiar methods necessary. He styles it "Callitype," and he has written a manual of instruction in the art which will doubtless interest many. Surely the photo-engraver will be interested in seeing that "Callitype" comes into more general use.—*The Illustrator*.

The complete specification of Patent No. 11,239, 1905, for the production of collotype plates (Carl Schaack, 18 Buckingham Street, Strand, London) is open to public inspection before acceptance.

Patent News.

process patents—applications and specifications—are treated in Photo-Mechanical Notes.

The following applications for patents were made between 29 and June 3:—

PRINTING FRAMES.—No. 11,283. Improvements in photographic printing frames. James Sidney Lenton, 18, Hertford Street, Coventry.

PRINTING FRAMES.—No. 11,365. Improvements in photographic printing frames. Walter Charles Grubb and Albert Nixon, Eagle Works, Durham Grove, Hackney, London.

PLATE CARRIERS.—No. 11,367. Improvements in adapters or plate carriers for exposing photographic plates or films in the camera. George Wishart, 96, Buchanan Street, Glasgow.

TELEPHOTOGRAPHY.—No. 11,385. Improvements in telephotographic objectives. Paul Rudolph and Ernest Wandersleb, Jena, Germany.

CINEMATOGRAPHY.—No. 11,447. Improvements in adjusting the gearing of cinematograph machines. William Frederic Butcher, 322, High Holborn, London.

DEVELOPING.—No. 11,452. Improved means of developing photographic images. Pierre Mercier, 18, Buckingham Street, Strand, London.

PRINTING FRAME.—No. 11,501. An improved photographic printing frame. Samuel Henry Adams, Scotswood-on-Tyne.

CELLULOID.—No. 11,512. Improved manufacture of celluloid. Auguste Bétal, Birkbeck Bank Chambers, Chancery Lane, London.

PHOTOGRAPHIC CAMERAS.—No. 11,585. Improvements in folding photographic cameras. Kodak, Ltd., 111, Hatton Garden, London. (Frank A. Brownell, United States.)

VIEW-FINDERS.—No. 11,670. Improvements in photographic view-finders. Arthur Lewis Adams, 26, Charing Cross Road, London.

COMPLETE SPECIFICATIONS ACCEPTED.

Specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

CELLULOID.—No. 15,435, 1904. The claim is for a process of producing celluloid in which the camphor is wholly or partially replaced by one or other of the following classes of compounds:—(1) Halogen derivatives (mono and poly) of primary amines; (2) acid derivatives (formyl, acetyl, ethoxalyl, and benzoyl) of a halogen primary amine; (3) acid derivatives (formyl, acetyl, ethoxalyl, and benzoyl) of the secondary aromatic amines, that is to say, such as contain an aliphatic and an aromatic radical with or without solvent, and, if necessary, with employment of pressure. J. Cox Gardner, 173-175, Fleet Street, London, for the Chemische Fabriken, vorm Weiler ter Meer, Verdingen, Rheinland, Germany.

REDUCERS.—No. 6,276, 1905. The invention relates to a reducer which fulfils the requirements of action chiefly on the denser parts of the negative, leaving the lighter parts, which need no reduction, in as nearly the original state as is possible. The claims are for: (1) As a photographic reducing agent, the use of salts containing cobalt the nitrite radicle group (NO_2 and potassium, sodium, ammonium, or other metals, with or without other acid radicles, in conjunction with an acid such as sulphuric acid; (2) a modified form of the foregoing reducing agent

wherein potassium nitrite, sodium nitrite or the like, and a cobalt salt, with or without a salt of ammonium or the like, are used in conjunction with an acid; (3) the use, in conjunction with a cobaltic reducing agent of the type set forth above, of a bath of dilute ammonia for the purpose of preventing discolouration or change of colour of the image after the reduction. One way of preparing the reducer is as follows:—Four grains of "Erdman's" salt, $\text{Co}_2(\text{NH}_3)_4(\text{NO}_2)_8 \cdot \text{K}_2$ are dissolved in 50 cubic centimetres of water by warming the water towards, but well short of, its boiling point. An orange-red solution is thus obtained which should be cooled (by cold water circulation round the containing vessel, for instance) until its temperature is 60 deg. or 70 deg. Fahr., for example, when an equal bulk (50 cubic centimetres) of dilute sulphuric acid of 15 per cent. strength is added. The mixed solutions may be allowed to cool or may be cooled if necessary by water circulation, after which the reducing agent is ready for use. The action of this reducer is selective to the required degree, as it attacks the deeper deposits of silver in the film on the plate, celluloid film, or paper, much more readily than the half-tone and lighter deposits; hence, by its use a hard negative or print may have its scale of gradation softened without the loss of any appreciable amount of the lighter deposits or half-tones. Indeed, if the reducing solution is allowed to act for a long enough period, it will be found in many cases to intensify the lightest deposits of silver whilst, at the same time, reducing the deepest deposits. The action of the reducer is slow, so that, unlike rapid reducers which quickly attack the light silver deposits, this agent will in use involve no risk of mistake by allowing the reducing action to go too far before the plate, film, or paper is removed from the bath. Harry Edmund Smith, 3, Ezra Buildings, Columbia Road, London.

PLATE AND FILM HOLDER.—No. 15,739, 1904. The patented holder is an open framework with a hook-shaped handle by which it is inserted into solutions, and by which, also, it can be fixed to a shelf or table as in the figure, so that the negative or film can

be set to dry. It is constructed of celluloid or similar suitable material. William Lawrence Parkinson, 3A, Imperial Chambers, 62, Dale Street, Liverpool.

The following complete specification is open to public inspection before acceptance under the Patents Acts, 1901:—

9,323, 1905.—Carpentier. Method of packing and changing sensitised photographic films and apparatus therefor.

CONGRATULATIONS to our good friend A. L. Henderson on the appearance of the following in Monday's "Scotsman":—"Golden Wedding. Henderson—M'Kenzie.—At Newington, Edinburgh, on June 11, 1855, by the Rev. D. M'Ewan, A. L. Henderson, youngest son of Thos. Henderson, surgeon, to Clementina M'Kenzie.

New Apparatus, &c.

The Stereo-Brownie Kodak. Made by Kodak, Ltd., Clerkenwell Road, London, E.C.

The recent revival of interest in stereoscopic photography has promptly brought forth a response from Kodak, Ltd., in the shape of a compact and serviceable stereoscopic film camera, at a very reasonable figure. The Stereo-Brownie, is, as its name implies, yet another member of the popular Brownie family, which seems to be growing apace of late, and like the other Kodaks of this series is a well-made and excellently finished little instrument, with all that is necessary to fulfil its maker's claims. It is of simple construction and weighs less than 30 ounces. The pictures of the stereoscopic pair measure $2\frac{1}{2}$ by $3\frac{1}{4}$ in. each, and the camera can be loaded or unloaded in daylight with spools for ten, six, or

four pairs of exposures. A brilliant finder with hood and screw bush for tripod work is included, and the pair of single lenses supplied cover excellently at full aperture. Both diaphragms are actuated by one movement thus ensuring identical openings. The shutters are of the overset automatic type, and are released simultaneously by either trigger or bulb release. The focussing arrangement is novel, and is the same as that in the No. 3 Folding Brownie, noticed recently in this column. By this ingenious device it is possible to set the distance scale before drawing out the bellows, and the camera front then becomes automatically locked at the required focal distance. As the complete apparatus costs only 50s. we think it will not only be an extremely popular addition to the series of Brownie Kodaks, but will, by reason of its efficiency and moderate price, do not a little to assist in the revival of stereoscopic photography.

The Busch Patent Camera Clamp. Made by the Emil Busch Optical Co., 35, Charles Street, Hatton Garden, London, E.C.

This useful little piece of apparatus has been introduced for use either separately or in combination with the Busch Pocket Stand. It is strongly made of metal, and can be made to grip anything not too large to insert in the jaws of the clamp. Used with the Pocket Stand screwed into a tree trunk or other support it forms a kind of bracket, and enables a large or heavy camera to be used without vibration. For attaching to the backs of chairs or edges of tables, etc., it is particularly useful, and is less likely to injure a polished surface than the Pocket Stand itself. The "Busch" Pocket Stand can be used in most cases to take the place of the ordinary tripod. It is made of well-finished metal, highly plated, and resembles somewhat a large gimlet. One end is provided with a screw which can be turned into any wooden foundation such as the trunks of trees, fences, etc. At the opposite end, on a hinged joint, are provided screws of both English and Continental sizes, which can be screwed into the bush fitted to the camera. The hinged joint allows the camera to be turned in any direction, and it can then be quite firmly clamped by means of thumb screws.

The price of the clamp alone is 3s. only. The clamp and stand complete costs 9s., and the entire apparatus weighs very little and can be easily carried in the pocket.

New Books.

Aide-Memoire de Photographie pour 1905. By C. Fabre. Paris: Gauthier-Villars. 1 fr. 75 c.

Le Developpement en Pleine Lumière. By Ernest Coust. Paris: Gauthier-Villars. 1 fr. 50 c.

For its abstracts of papers scattered through the press and arranged in order by M. Fabre, we have reason to esteem past issues of the "Aide-Memoire," and no doubt its statistical information is reasonably correct, so far as it applies to France. But the particulars of English societies and periodicals stand in lamentable need of revision. In giving the society officers, the compilers apparently make a practice of appending the secretary's address to the president's name, and a great many of their facts are incorrect. The list of periodicals is full of errors, but by an obvious inspiration one of the late contemporaries is being considerably removed by degrees, and figures as "The Photographic Art Journal."

"Photography without a dark room" is M. Coustet's theme, and he tackles it in a half-hearted sort of way. If he is arguing in favour of development in a fully-lighted room, why does he wander into questions of dark-room illumination and monochromatic lights, particularly as he does not object to detail such debateable points as the merits of non-actinic candles—i.e., candles with stearate of lithium or stromtium in their composition, and intended to give a red illumination? Yet he has three of his sixty pages occupied with this topic, and not as much with the Kodak and other development machines. The most valuable part of his work is that which relates to coloured developers, in which are given the formulæ of Lumière and others for this ancient, but spasmodically resuscitated, process.

Booklets published for the Town Councils of Deal, Leamington, and Southwold reach us from the Health Resorts' Development Association. In view of the approaching holiday season, it may interest our readers to know that they are sent free if a postcard request is sent to the town clerks.

A PHOTOGRAPHIC Section is announced in connection with the forthcoming Armagh Agricultural Show, to be held on June 28 and 29, in the beautifully situated Palace Grounds, Armagh. Full particulars will be sent by the Secretary, Mr. Albert E. Craddock, 10, Colles Street, Armagh.

COLOUR PHOTOGRAPHY.—At a meeting of the Academy of Science on Tuesday, M. Lippmann read a paper dealing with the results of his further study of the difficult problem of colour photography. M. Lippmann's record of his researches was of a highly technical but interesting nature, and proved that a considerable step forward has been made in the direction of a practical process of photographing in colours.

PHOTOGRAPHIC Society for Lowestoft.—A meeting was held in the Y.M.C.A. Hall, Lowestoft, on Monday of last week, for the purpose of starting a camera club. Dr. Hutchinson presided, and explained the object of the club, which it was decided should be started. The officers were elected as follows:—President and chairman, Dr. Hutchinson; treasurer, Mr. H. A. Northcott; committee (not exceeded in number eight besides the other officers), Messrs. H. C. V. Blyth, R. Bush Stafford Cox, H. Tansley, and C. Taylor; secretary, B. Corbyn. The secretary or treasurer will be pleased to receive the names of any one wishing to join.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Time.	Name of Society.	Subject.
.....	Bowes Pk. and Dis. Ph. Soc.	Outing, President's Day, Knebworth Park.
.....	Hull Photographic Society	Outing to Brock of Dale Woods.
.....	Cricklewood Photo. Society	Trip to Hadley Woods.
.....	Glasgow Southern Ph. Assn.	Inverkip. Joint Outing with the Photographic Section of the Paisley Philosophical Institution.
.....	South London Photo. Society	"The Development of Rapid Plates."

.....	Devonport Camera Club	Trip to St. Michael's Mount.
.....	Everton Camera Club	Day Outing to Mold for the Logger-heads, &c.

THE PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

MEETING of the General Committee was held at 51, Baker Street, on Friday, the 9th inst. Present: Messrs. F. A. Bridge, A. S. Wm. Grove, M. Jacolette, A. Mackie, D. Prodder, E. Scamell, G. Sims, and R. Fellows Willson; Mr. Alfred Ellis, Past President, the chair.

Letter read from Mr. Pirie Macdonald, President of the Professional Photographers' Association of New York, addressed to Mr. Wm. Grove, the Hon. Secretary, thanking him for the kindly sentiments expressed on behalf of the Committee on the institution of their Association, and notifying that a copy of "The Photographer," of New York, containing a full account of the initiatory meeting had been sent.

The discussion was resumed on the admission of certificated assistants to certain privileges of membership, and it was finally decided that the Committee would recommend to the members at the next annual general meeting that the rules be amended to provide that certificated assistants be entitled to all advantages of membership except that of voting and taking part in the administration of the Association—upon payment of a registration fee of 1s. per annum. The draft of the certificate was submitted, and it was ordered to be printed and a proof sent to each member of Committee previous to the next meeting.

It having been pointed out that it was the custom of the Committee not to meet during the months of July, August, and September, it was decided to hold a meeting on Friday, June 30.

The remainder of the meeting was devoted to the discussion of the details of the proposed circular. An estimate was submitted of the cost of printing, etc., and approved—four numbers to be published annually at such intervals as might be found convenient.

ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held Tuesday, June 15. Messrs. S. E. Sheppard and C. E. Mees read a paper on "Some Points in Modern Chemical Photography Bearing on Development." The authors reviewed the conception of modern physical chemistry and dwelt in particular on the relation of solutions and the course of chemical reactions. In the case of solutions it was customary to distinguish between solvent and solute (the body dissolved), but such distinction was purely arbitrary,

though in the case of dilute solutions was a convenient one, for from it came the generalisation that "the solvent affords a free space for the action of the solute, but is otherwise inert," i.e., it acts as a vacuum in which the solute behaves as a gas. This conception, the authors said, had been useful in the past, but would require modification in its application to more concentrated solutions. The "osmotic pressure" of bodies in solution was likened to that of a gas, and reference made to its measurement by hydrostatic pressure in vessels with semi-permeable membranes. Osmotic pressure had analogies with gaseous pressure as expressed in the laws of Boyle, Gay Lussac, and Avogadro, and a study of osmotic pressure led to the discovery of dissociation in solution and the Arrhenius theory of electrolytic dissociation, with the important bearing of the latter on chemical reactions by means of ions. In discussing the course of chemical reactions in the light of modern physical chemistry, it was pointed out that chemical equilibrium was reached when the velocities of two opposing processes are equal, a special case of the law of mass action. One important class of chemical reaction is when one of the reacting bodies is a solid, in regard to which it was insisted that chemical theory does not recognise a reaction between a solid and a liquid. When chalk, for example, is dissolved by an acid, a little chalk is first dissolved by the water, and this is then the "active mass" which reacts with the acid. It could be stated generally that every substance was more or less soluble or has a definite "solution pressure," and its activity in solution may be measured by its concentration. The authors proceeded to apply these views to the development of a photographic plate. A brief discussion followed, in which Mr. J. Sterry, Mr. Sordes Ellis, and others took part.

SUTTON PHOTOGRAPHIC CLUB.—The annual meeting was held on the 7th inst. During the year interesting and instructive lectures and demonstrations were given, several excursions made, and the portfolio circulated. The membership had increased, and there was a good cash balance. The following officers were appointed:—Chairman, Mr. Hector Maclean, F.R.P.S.; vice-chairman, Mr. A. P. Hoole; committee, Messrs. W. R. Baker, G. W. Bradshaw, F. Nicol, and E. B. L. White; hon. secretary and treasurer, C. Thwaites, M.Inst.C.E., F.R.A.S.

THE Phototype Company, of Orchard House, Hounslow, have purchased Miss E. M. Cocroft's painting, "The Widower," now being exhibited in the Royal Academy, and have published some very fine engravings of the picture. The subject is somewhat sentimental in character, but will appeal to the large class of buyers who admire good clean work, and like a picture that tells a tale. The Phototype Company, having purchased this copyright, will supply proofs on Japanese vellum at £6 6s., artists proofs at £2 2s., and engravings at £1 1s.

DELIGHTS of Gum Printing!—We read in the organ of a Midland Photographic Society that gum prints may be fixed in alum or carbon bisulphide (the italics are ours) to remove objectionable bichromate stain. And still the writer can commence: "This fascinating process. . . ."

WITH the approval of the Prince of Wales (the President), the Council of the Society of Arts have awarded their Albert Medal for the present year to Lord Rayleigh, "in recognition of the influence which his researches, directed to the increase of scientific knowledge, have had upon industrial progress, by facilitating amongst other scientific applications, the provision of accurate electrical standards, the production of improved lenses, and the development of apparatus for sound signalling at sea."

News and Notes.

THE sixth Congress of Practical Chemistry will be held in Rome during Easter, 1906. The President of the Societa Fotografica Italiana (50 Via Alfani Florence) as President of the Section "Photochemistry and Scientific Photography," invites all who are interested in these subjects to take part in this Congress. He kindly requests to be informed, as soon as possible, of the subjects of the communications which may be offered for discussion. The programme of the meetings and excursions will be announced in due course.

CELLULOID Fire.—A fire broke out last week in a shop in High Street, Attleborough, where fancy goods were displayed. These suddenly burst into flame, and it was found that the rays of the sun had been focussed through the glass on to some celluloid combs, which blazed up and fired a quantity of other articles.

COMPRESSED Oxygen.—An incident which has caused some uneasiness is reported by the "Bollettino Chimico Farmaceutico." Father Geroni, of the Minore Osservanti, Florence, has sent a letter to the journal, "Il Fieramosco" saying that whilst giving a lantern lecture the oxygen ran short, and a new cylinder was obtained from a neighbouring chemist. The new supply did not give so good a light as the original, and it was discovered that the cylinder contained one-third oxygen and two-thirds compressed air. He went to another pharmacy and got another cylinder, which the proprietor on examination found to be purely compressed air, containing just the percentage of oxygen to be found in the open air. The Florentine pharmacists regard the report as exaggerated.

MESSRS. SARAFIAN BROS., photographic works and photographic dealers, Beirut, Syria, notify us of the enlargement of their premises, and state that their establishment now contains nearly everything that is needed for photography, i.e., apparatus of various makes and sizes, lenses, plates, papers, accessories, etc. Also pictorial photo. scenes, postcards, gravures, artistic materials, etc. Manufacturers are respectfully requested to forward their catalogues together with particulars of their specialties and novelties, with samples where possible, giving the very best terms.

ACCORDING to "The Photographer" (New York), the Lewis and Clark Exposition to be held at Portland will include, by special invitation, twenty-five photographs in its Fine Art Department, a mark of appreciation which St. Louis did not grant the photographers. The twenty-five pictures were selected for the management by Messrs. Herzog, Steichen, Keiley, and Stieglitz, and are the work of Messrs. Herzog, Steichen, Keiley, Stieglitz, Coburn, E. S. Curtis, Dugmore, Dyer, Miss Devens, Eickemeyer, Eugene, Mrs. Kasebier, V. B. Post, Mrs. Sears, Seeley, and White.

A CIVIL Service examination to appoint a Velox printer strikes us in this country as an act of supererogation, but in filling two vacancies of this kind in the Geological Survey at salaries of £250 and £180 a year, examinations were held in Brooklyn, N.Y., recently, and the candidates appointed by their marks for proficiency in the handling of gaslight papers, their experience in practical work, and their knowledge of dry plates, lenses, and enlargements.

OUR American contemporaries always interest us. The current issue of one of them positively excites us, announcing, as it does, a "Rotograph Carbon Lens," which is "prepared at present in twenty colours, while other colours are in preparation." But we hope nobody with misunderstand the real point a—tissue!

GLASS opaque to ultra-violet light is a material of importance to photographers and process operators now that artificial illuminants exceedingly rich in these rays (such as the enclosed-arc and mercury-vapour lamp) are more largely employed. There is the danger of

injury to the eyesight by protracted exposure to illumination of this kind, and therefore the opaque glass which Messrs. Dolland and Co., 113, Cheapside, E.C., are introducing in the shape of "Isometre" spectacles, should receive attention. We recently witnessed a demonstration of the stopping power of an "Isometre" spectacle lens towards ultra-violet light, and we learn from a booklet which Messrs. Dolland issue gratuitously, of the many advantages of these spectacles. The glass itself, possibly, may be found of some photographic service.

ALL the leading photographers of San Antonio, Texas (according to "Wilson's") have joined in a movement to abolish ticket scheme and fakirs, to close all studios on Sundays, and to meet frequently for general good-fellowship. That such a movement as this should come from San Antonio seems remarkable. It is, none the less, to be hailed as an important indication of growth and business acumen.

THE Thornton Pickard competition for 1905 has a special interest for professional photographers, as a new class is instituted, viz. one for pictures taken with the Thornton-Pickard Studio Shutter used either in or out of the studio. Ten of the total £100 presented to the prize-winners are allotted to this class. A circular of the competition has just been issued by the Thornton-Pickard Company Altrincham, and will be sent on demand.

NEGATIVES WANTED. For some months the Rotary Photographic Co. have offered in "The Bromide Monthly" certain special cash inducements for photographers to part with negatives of subjects suitable for post-card and other purposes. This offer they have now made a standing one, and will send particulars of it on application.

PHOTOGRAPHIC Materials Abroad.—A correspondent who sends the following letter to the "Times" of Tuesday last appears to have had an exceptional experience. No one, we imagine, expects the foreign dealer to keep a great stock or variety of British plates, and though we ourselves prefer to take a full supply with us rather than rely on purchases en route, we have, on occasions, been surprised to find we could purchase British plates in small towns in France and Switzerland. As a matter of fact, taking up the current issue of an Italian photographic journal we find three leading makers of British plates prominently advertised. If the "Times" correspondent had consulted one or other of our foreign contemporaries he would probably not have had cause to make his complaint:—"In spite of the excellent state of affairs in our photographic trade, as shown by your articles of some two months back ('Financial and Commercial Supplement,' March 27 and April 3), one cannot help wishing the traders had more of the 'go' of their Transatlantic rivals. During a recent stay in North Italy I made numerous efforts to obtain English plates, yet Venice was the only town in which I succeeded, and here the trade appeared to be confined to one shop, which kept a very small stock of two of the leading English makes. On the other hand, Kodak specialties were obtainable everywhere, and in Venice alone there must be a dozen agents. Previous to leaving England I endeavoured to find out from the manufacturers where their plates were to be got. They could only give me the name of the wholesale agent for all Italy, with whom I had not time to communicate even if he would have supplied the information. Surely it would be worth while to secure the custom of the thousands of English travellers who would so much prefer to use the plates they know. So little is needed to ensure a good sale. An advertisement in the leading hotels, an arrangement with the various tourist agents, and a knowledge by the manufacturers themselves of the addresses where their goods are obtainable in the chief Continental towns would secure a considerable increase of trade. Inability to obtain English plates on the Continent must influence the choice of a camera in favour of a Kodak, and hence affect the home consumption of plates."

Commercial & Legal Intelligence

Exeter County Court last week, before his Honour Judge Lush, a case was heard, in which Annie Spencer, of Manchester, John Parsons, of Melbourne-street, Exeter, on a judgment to recover £36 13s. 6d. Defendant was examined by Mr. Brown, who represented the plaintiff, as to his means. He the amount due was the result of interpleader proceedings and costs due thereon. Mr. A. Martin Alford, for the respondent, his client was one of the victims of the plaintiff's husband, Spencer, who carried on business as the Midland Photo Company, Birmingham. In August of last year the defendant was d, as were many others throughout the country, to hand £100 on being promised a managership in one of his branch. Needless to say, defendant was never appointed. Within a or so of the payment of the £100, Spencer turned himself into ted company, and within a very few months this company, was practically a one-man company, went into voluntary tion. In February last the defendant obtained judgment t the man Spencer for £100. Spencer was at that time living rge house in Birmingham, and defendant, wishing, if possible, sin, at any rate, a portion of his £100, levied execution on his

On the sheriff's officer going to levy, it was found that only oms were furnished, and these very poorly, and the sale pro- only £21. Out of this rent and taxes were a first charge, he result that only £5 18s. 3d. was credited to the defendant. urniture was claimed by Mrs. Spencer, the present plaintiff. ant was too poor to fight the interpleader action, with the hat the unfortunate man was now asked to pay £36 13s. 6d., ount of the interpleader order, and costs. Mr. Alford suggested e plaintiff should get the amount due from her husband, who ill owing the debt, on a judgment, £100 and costs. His said it was a sad case, but the question was the defendant's . He made an order of 6d. per month only. The defendant ld man living in lodgings, and if he discharges the debt at e he will have to live another 120 years.

ERE North American Company.—For the year ended Feb- 23 the accounts show that, after charging the sum of £571 eciation of the Burlington plant, a balance of £2,235 remains. sum the directors are of opinion that at least £1,700 should ined to meet the probable cost of an action to be brought the company.

GRU Frauds by a Canvasser.—At the North London Police on June 8, James Watson, a clerk, with no fixed abode, was with stealing a half-sovereign belonging to a domestic servant, Turnbull, of Alwyne Road, Canonbury. The prosecutrix said May 29 the prisoner called at the house where she was ed, showed her some specimens of photographs, and induced give him an order. He said he was canvassing for a firm printed circulars he produced. She agreed to pay him 4s. but had no silver, so she gave him a half-sovereign to get t. But he did not return, and she heard no more as to her d photographs. It was stated by the detective who arrested t that there were complaints of similar frauds upon servants the metropolis. About a year ago the prisoner was arrested ilar charge, but the servants would not come forward to give t. The prisoner was remanded.

Sutton Photographic Club's first excursion of the season will to-morrow, Saturday, June 17, to Warnham Court, which le for its picturesque scenery and its gardens, and for its ection of modern pictures, Japanese and other art objects, and old iron work of Surrey. Mr. Hector Maclean will the excursion. The second excursion will be on July 1, at trip from the Old Swan Pier to Greenwich, and the ursion July 15, Leatherhead to Boxhill.

PLATINUM PRINTERS' CATARRH.

To the Editors.

Gentlemen,—I have read with interest the correspondence in your columns under the heading of "Platinum Printers' Catarrh." The letters on the subject certainly seem to show that the manipulation of the platinum process causes some kind of ailment. One of my assistants, who did a lot of platinum work, was greatly troubled with a kind of asthma, which is, I understand, caused in a way by catarrh. He was so bad that he passed night after night without sleep, and frequently had to absent himself from work. The worst attacks seemed to come after a fine day (after a big batch of prints). For the last six months he has not done any platinum printing, and has not suffered in any way from his asthmatical trouble.

Some years ago I did a lot of platinum printing, and used to wonder why I nearly always had a cold in the head.

If it is proved that platinum printing causes catarrh, it would be useful to have the views of your correspondents on the particular part of the process which is responsible for it. For my part, I would blame the hydrochloric acid, the fumes of which are very strong whilst being poured out of a bottle to make the necessary solution, and very likely inflame the mucous membrane (which is the cause of catarrh). It is also possible that the fumes from the developing solution, whilst being warmed, will have a similar effect. If it is the acid, would it be advisable to have bowls of a solution of ammonia about the developing-room to neutralise the acid fumes or act as an antidote?—Yours faithfully,

T. EVERITT INNES.

Heaton Chapel, June 12, 1905.

[We cannot conceive that the weak acid fixing baths employed in the platinum process can be responsible for the trouble alleged to arise from platinum printing. Certainly there is nothing evolved from the hot oxalate bath to cause irritation. It is true that oxalates do undergo a slight decomposition at boiling heat, but the volatile product is only innocuous carbon dioxide gas, and even that in minute quantities. On the assumption that there is a direct connection between the ills experienced by our correspondents and the working of the process, the most likely cause, as we have already stated, is oxalate dust; and no extraordinary care should be needed to maintain the necessary cleanliness. Since the question has arisen we have consulted a physician, who tells us that not a single case of the kind is known to him, personally, and after a search through medical literature for many years past. We are also informed by a well-known authority on catarrhal affections that the conditions, as stated, appear to him quite insufficient to account for the symptoms.—Eds., B.J.P.]

PHOTOGRAPHIC APPRENTICES.

To the Editors.

Gentlemen,—In your issue of the 9th inst., there is a very pitiable statement from a correspondent signing himself "Assistant." It appears that for four years he served his time under indentures to a photographer, receiving the usual low apprenticeship remuneration, and that his reward, after all his years of labour, was to stay on for five months at the munificent salary of 16s. per week! Now he finds that his services are not valued by the profession at more than 25s. per week, and as a printer only.

We should have thought that in four years he would have become at least a fair all-round photographer, for the operating and printing

are mainly mechanical processes; although to excel at either means, as with all other professions, gifts of taste, observation, and refinement, as well as special ability.

"I was never taught retouching," he states. Now, that is just the point upon which we would like to remark. Why do apprentices ever hope to learn retouching, miniature painting, tinting and finishing in B. and W., properly, in the firms employing them; and why do employers ever hold out such fallacious hopes to the apprentices? Each branch enumerated is distinct in itself, and requires a skilled teacher to impart really serviceable and artistic knowledge. Photographers do not keep tame instructors on the premises for the benefit of apprentices! and nine times out of ten, in good-class firms, the chief does not retouch or paint at all, but devotes all his time and energies to the operating and supervision of his business.

He employs more or less capable artists and retouchers, but they are decidedly not teachers; and, when he asks them to kindly show Mr. Apprentice how to do their respective branches of the business, is it likely they are going to trouble much about it when they are already full up and weary with their own work, and when the advancement of the apprentice may mean cutting their own throats in the future? Even with the best intentions, it is more than they contracted for when employed, for they were engaged as workers, not as teachers of others—they have had no experience in tuition, and do not care a rap about it. Many of those already earning their living as B. and W. artists, retouchers, miniaturists, and tinters are open to very considerable improvement in speed and finish; and to these defective assistants, in many cases, the apprentice has to look for his knowledge! It is the blind leading the blind.

There are exceptions, of course; and many firms thoroughly fulfil their obligations to their apprentices; and these words are directed solely to those photographers who so readily undertake responsibilities they know quite well they cannot justly carry out.

We have heard of lady apprentices, especially, who seem to pick up spotting, mounting, burnishing, printing, working up plat. and bromide prints to a fair extent, but who hardly possess a glimmering of retouching or B. and W. finishing, and who, in miniature painting and tinting, are even more defective. The men appear to learn operating and studio routine, and are generally well up in printing, but their retouching and B. and W. work will seldom bear criticism. The fact remains it is downright absurd for employers to expect such Admirable Crichtons! The photographer is asking too much from the one limited brain.

We see advertisements such as this:—"Wanted, Operator-retoucher (skilful with children); B. and W. artist; own aerograph; one who can paint in oils preferred, etc., etc." Man wants but little here below! You may get an assistant with a smattering of each subject, but he cannot be first-rate in all branches, especially for the wretched remuneration too often offered—hence the general turn-out suffers!

We respectfully suggest to the profession that employers teach the work that they do thoroughly understand, and that they advise their apprentices to take lessons in the other subjects from skilled teachers who have made tuition in these branches their special study. General photography would be greatly improved and more artistic ideals would prevail. This would be fair to the employers and fair to the apprentices. They would at least no longer live in a fool's paradise, but at the end of the three or four years be well equipped in all branches, and fit for the battle of life. Employers might allow special and suitable hours for such studies; and then they would not have to read such damaging statements as that made in your correspondence columns of last week—and, by the way, would not have to run the risks of after litigation, as suggested by your reply!—Yours truly,

X. Y. Z.

June 10, 1905.

MODERN CHEMISTRY.

To the Editors.

Gentlemen,—As one who for some time past has given up active work in chemistry, I have followed Mr. Mees' papers on "Modern Chemistry for Photographic Workers" with interest. But I must confess to a certain amount of disappointment at the net practical outcome of the application to photographic processes of the modern theories of physical chemistry.

As the result of five papers on the subject, we learn that development may equally well be regarded from the point of view of ionic interaction as from the old-time point of view of molecular interaction involving simultaneous oxidation and reduction. But is the ionic interpretation really any more explanatory or illuminative of photographic processes than the older interpretation? Do ionic considerations suggest any vital modifications of established procedure, or do they more distinctly point out the directions of further research to the investigator who would further illuminate the yet gross darkness of the dark room? Apparently not; and herein lies the disappointment.

There are, I think, one or two points in Mr. Mees's papers which are worthy of comment.

In the fourth article of the series (May 26), the statement is made that the reaction

$$\text{Ag} + \text{Br} = \text{AgBr}$$

is not reversible because the AgBr is removed from the sphere of action by precipitation. But surely the modern view is that no such insoluble precipitate is absolutely insoluble; and hence that no body is completely removed from the sphere of action by precipitation. For instance, though for the purposes of analytic chemistry BaSO₄ is regarded as absolutely insoluble, yet, as a matter of fact, BaSO₄ is soluble to such an extent that the proportion thereof present in the saturated solution is some fifty times greater than the proportion of radium in pitchblende. Similarly, when the reputedly insoluble AgBr is placed in water a little of it dissolves; the dissolved portion, being of very low concentration, dissociates almost completely into its ions; and it is only when the product of the concentrations of the Ag and Br ions equals the "solubility product" that equilibrium reigns.

The reaction

does then take place; or, in other words, the reaction

is reversible, as Mr. Mees himself further on in his articles implies when describing development from the modern standpoint.

The statement of Faraday's law, in the article of May 12, is liable to misinterpretation. "One atom of an element can only carry one electron of electricity." This is a very *ex parte* statement of Faraday's discovery, being true only for monovalent atoms, such as Ag. Faraday's law is that the electrical conveying powers of atoms are proportional to their valencies, so that divalent atoms, like copper, carry two electrons; trivalent atoms, like aluminium, carry three electrons; and so on. These fundamental facts are, of course, implied by Mr. Mees in other portions of his papers; but, surely, to avoid misunderstanding, direct statement should replace implication in articles which are professedly for the non-expert reader.

It is rather unfortunate that in his laudable attempt to explain the physical significance of a differential coefficient, Mr. Mees should use as an illustrative example the fall of a body, falling as no body ever falls in nature.—Yours truly,

DOUGLAS CARNEGIE.

Blackheath, S.E., June 10, 1905.

Answers to Correspondents.

* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C. Inattention to this ensures delay.

* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

* Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.

* For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 1d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

Dykes, Challenger Office, Villa Medusa, Boswell Road, Edinburgh, N.B. Photograph of Torpedo-Boat Attack on Channel Fleet and Cruiser Squadron, taken at 12.10 a.m.
 John Bailey, 73, Shirley Road, Southampton. Photograph of Captain Barr and crew of "Atlantic."
 Lockyear, 898, Hyde Road, Gorton, Manchester. Photograph of the Grotto, Pomona Hotel, Manchester.
 Hodgson, 93, Pinstone Street, Sheffield. Photograph of the Sheffield University.
 H. Greenway, 27, Abington Street, Northampton. Photograph of Northants Cricket Club Team.
 Sharp, 38, St. Nicholas Street, Aberdeen, N.B. Photograph of "Robinson Crusoe" Pantomime, Palace Theatre, Aberdeen, 1905.
 Howard, 80, High Town Road, Luton, Beds. Two Photographs of Stockwood House, Stockwood Park, Luton.
 Philip, George Place, Bo'ness, N.B. Photograph of the Rev. W. Smith Hunter.

POSTCARDS.—Will you kindly give the name of any firm that publish a book on pictorial postcard work of all kinds? We wish to know what machine would be required to make same.—W. GORDON.

No such book is published to our knowledge.

ELATINE AND ACETONE.—Can you inform me if there is any chemical which will repel acetone. I wish to treat a gelatine film with acetone, but do not wish it to penetrate the gelatine. I have tried hardening the film with alum, formaline, and I have also tried chrome-alum, but the acetone gets through more or less, with all. I consider that if the gelatine could be treated with a repellent chemical (other than varnish) it might make the gelatine proof against the acetone.—A. R.

We can suggest no further treatment, except, if it were permissible, of giving an extra thick coating of gelatine to which 10 per cent. of formaline was added whilst the gelatine was in the fluid state. Gelatine is insoluble in acetone, and therefore we can hardly understand the acetone getting through if a perfectly homogeneous film were used.

HARRIS.—1. You will find two or three formulæ in the "B. J. Almanac" for 1905, p. 1029. 2. If you want a matt or half-matt surface, sizing is unnecessary; if you want a highly-glazed surface, the paper is unsuitable, and you must use baryta paper.

ENLARGE.—1. It is against our rule to do what you suggest. 2. To do all that you require with a gaslight enlarger you will want a condenser large enough to cover a 12 by 10 plate. The price of this would be very considerable, and we do not advise you to get one unless another illuminant is used. You will want an 11-in. condenser for enlarging from whole-plate. A 16-in. condenser would be necessary to fully cover a 12 by 10 plate, but, with suitable carriers, the 11 in. would serve to enlarge from portions of larger negatives. 3-4. You will find a good-class anastigmat, with large aperture, the best

type of lens for your purpose. The portrait lenses usually supplied with enlargers have a round field, and are not so suitable for enlarging sharp up to the corners of the plate unless considerably stopped down. 5. The same objection in a lesser degree applies to the R.R. lens. An anastigmat by a reliable maker will have a flat field, and will cover the plate perfectly to the corners with full aperture. The R.R. or portrait lens will not do this unless, say, a whole-plate lens is being used to enlarge from a quarter plate.

BROMIDE.—It is difficult to offer an opinion as to the cause of the markings without seeing the print, but, in any case, it is not wise to add anything to the fixing bath. Always use plain, freshly-made hypo solution, and fix and wash thoroughly. If it is necessary to harden the gelatine surface, use a dilute solution of formaline separately—either before or after fixing.

SULPHIDE TONING.—Can you kindly help me in the following questions?—A demonstration on bromide paper toning (sepia) was given by means of two methods—(1) By copper sulphate, nitric acid, and soda sulphide baths; (2) By iodide, soda sulphite, and soda sulphide baths. A tendency to yellowish-brown colour was obtained on some papers; this is my trouble, also. Mr. J. Sterry stated that by using a 1 per cent. solution of potass metabisulphite warmer colours were obtained, and free from yellowness. Query: When, and how, should this solution be used?—CONSTANT READER.

We should say the metabisulphite bath is used instead of the sulphite solution in process (2). There would be no advantage in using it after copper sulphate. If you cannot succeed with the formulæ, why not test your manipulation by one or other of the "sulphide" toners supplied ready made?

R.—We do not think you can blame the water. It is obvious, from the sharply-defined lines on some of the cards, that they were allowed to lie one over the other, and were thus not sufficiently fixed. As the cards are so thick, it is necessary to be very careful about this point, and to leave them longer in the bath than ordinary prints, and to wash them more thoroughly.

RETOUCHING.—(1) I shall esteem it a favour if you will kindly give your opinion of the enclosed specimens of my retouching. They were executed at various times during the last few years, and in many cases the time occupied is not noted. (2) Please say what salary you think I should secure (I am now working for myself). (3) Is the work sufficiently good for a high-class business?—RETOUCHER, Tunbridge Wells.

You send too heavy a batch. Our space is limited, and three samples of the unretouched and the retouched should suffice for the ordinary requirements of inquirers. (1) Your retouching is not first-class, for it is lacking in feeling and softness, and the numerous prints show too similar a treatment. Your own likeness should be much bolder in the texture for this sized face. The freckled girl is merely smoothed up, and the shadows left in too raggedly—the effect is hard! The man with white whiskers is the best effort, but you were too formal and heavy on the lead. Less work on his wrinkled brow would have made for better effect and preservation of character. The retouching is very coarse and broken-up on the children, and opening their eyes is hardly an improvement. The unretouched is a natural and rather comical picture, whilst the retouched is strained, and probably not a likeness. Unless the children could not be taken again, this eye-opening effort is not justified. If it is to be criticised as a piece of knife-work then it is too beady, and should have been pencilled down. Prints sent should not be spotted or worked up. The fine grained copy

of man for enlarging is very good, but the woman is too stiff and white—an unpleasant and difficult subject. (2) We should think about 30s. to 35s. per week. (3) Your work is not up to the highest-class requirements.

RETOUCHING.—(1) Would you kindly pass your opinion re the enclosed prints, which are from negatives of my own work. I enclose prints, toned and fixed, before retouching and after. (2) I have only begun to retouch (learning myself) about two months ago. I know the enclosed prints are not up to the standard to gain a situation, but I should be pleased for your opinion. (3) What do you think I could expect as a retoucher and operator? What hints I have obtained in retouching have been through your valuable paper re inquiries on retouching.—N. E. L.

(1) The retouching is of very poor quality, and the operating is almost in the same category. (2) Two months' study of retouching under the conditions you state are not sufficient to make anyone competent to take a situation. You would benefit by some lessons. (3) Your retouching at present is almost worthless, as it possesses no finish, but for your operating we should consider 25s. per week the best you could secure; but it is always difficult, nay, almost impossible, to judge from such slight evidence of the inquirer and his work.

DRY MOUNTANT.—The formula is (from our issue of May 12):—Shellac, white or yellow, 30 gms.; methylated spirit, 50 ccs.; dissolve, and add gum elemi, 3 gms.; Canada balsam, 5 gms.; methylated spirit, 50 ccs. It takes about twelve hours for the shellac to dissolve; mix the two solutions, and paint both sides of a thin piece of paper and allow to dry; place the paper between the mount and the print, and pass a hot iron over the print, when it will adhere well.

FRENCH STOPS.—I have a French pocket camera with a R.R. lens, "Le petit Bob Idéal," but as the stops are marked in the French way, I shall be glad if you will let me know through your columns the corresponding English numbers. The stops are marked thus, 3, 6, 9, 12, 15, 18, No. 3 being the smallest.—F. C. ROBINSON.

It will be best for you to ascertain the *f* numbers for yourself by measuring the diameter of each aperture and dividing by the distance between this latter and the plate when the lens is focussed at full aperture on a distant object.

YELLOW SCREEN.—In the "British Journal Photographic Almanac," for 1905, there is an article on "Orthochromatic Prolegomena," page 841, by Mr. George T. Harris, F.R.P.S. The writer says on page 846: "To be useful the colour must be a bright lemon yellow, a colour rarely seen in glass, which is usually brownish yellow. The filter used with the illustrations here given was a ammonium picrate, similar to the one originally described by me in the 'British Journal Almanac' for 1893, and I think it would be difficult to beat it for all-round landscape work. "Would you kindly give me full particulars to make a shade (or buy one) similar in every respect to the one Mr. Harris speaks about, and if possible the kind of orthochromatic plates to use?"—J. H.

The instructions given by Mr. Harris in 1893 were, briefly, as follows:—Prepare a glass plate with beeswax as if for enamelling, and coat with a 20 gr. sol. per ounce of Heinrich's hard gelatine. When set, immerse the plate in ammonium picrate solution, 5 grains per ounce, and dry. The gelatine film can then be stripped off and mounted in a collar of stout leather to slip over the posterior combination of the lens. We believe screens from Mr. Harris' formulae (not necessarily those given above) are supplied by Messrs. R. and J. Beck.

COPYRIGHT.—Could you give me your opinion of what I should do in this case? I give one of my negatives to a professional photographer to get some enlargements done. While he has it he makes, without my consent, an enlarged negative off mine; then takes out a copyright on his negative. When I get my negative returned I get my original negative copyrighted. Now the professional photographer is selling prints off the enlarged negative, and when requested to stop he declines. Have I any power to compel him?—JOHN DAVIDSON.

Certainly you have. As you took the original picture the copyright is vested in you, and now that you have registered it you can obtain an injunction restraining the photographer from selling any copies of it, and also recover damages, from the time of your registration, if you can show that you have sustained any loss. The professional's registration is of no use, as the copyright was not his to register. It was a mean thing to attempt, and we should have thought no respectable photographer would have stooped to it.

COLLOTYPE IN NEW ZEALAND.—I should feel highly obliged to you if you could inform me of any firms you might know of that do colotype in New Zealand, or where I might be able to find such information?—INK-PHOTO.

Possibly Wilson and Horton, Wyndham Street, Auckland, or The Weekly Press, Limited, Christchurch. Probably Messrs. Penrose and Co., 109, Farrington Road, E.C., Messrs. Hunters, Limited, Poppins Court, Fleet Street, E.C., or Messrs. Furnival and Co., St. Bride Street, London, E.C.—all dealing with colotype printers and plate-makers—might be able to tell you.

ANXIOUS.—1. Better ask your local police to have a call made on the party. 2. A good formula is:—

A.	
Metal	400 gr.
Soda sulphite	8 oz.
Potass. bromide	50 gr.
Water	80 oz.

B.	
Potass. carbonate	8 oz.
Water	80 oz.

Use A three parts; B one part.

REGISTRATION.—I publish a photograph on a specially worded mount.

Can I have this mount protected by copyright or registration? It is the wording on the mount I want protected chiefly. Can you tell me about the cost and the proper way to proceed?—R. B. GILPIN.

The words cannot be registered under the Artistic Copyright Act. It is possible that the words may be registered under the Trade Marks Act, but as we do not know what the words are we cannot give an opinion. Better write to the Patent Office (Trade Marks Department), Southampton Buildings, W.C., enclosing a stamp for postage, for a copy of the rules.

TITLES.—You should get the "Nameit" outfit, to be obtained from your dealer.

**** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

EX CATHEDRA.

The Focussing Cloth. The ubiquity of the modern hand camera has done much to render the voluminous focussing cloth beloved of Cuthbert Bede of less importance than it was to the amateur of a decade ago. Focussing scales and roll films have tended in many instances to render the use of the familiar square yard of black velvet unnecessary, but we venture to think that the productions of photographers dependent on a distance scale and a viewfinder—often absurdly small and inefficient—do not and cannot compare with the photographic work of those who study their subject in the enveloping shadow of the focussing cloth. Certain subjects there are which do not permit of viewing on the ground glass, but in the majority of cases far better results undoubtedly accrue to the user of a hand camera with a focussing screen if a light tripod and focussing cloth are carried and used more often than appears to be the case with the bulk of present-day amateurs. There is no need to carry a heavy, nor yet extremely large, cloth. The waterproof focussing cloths which are obtainable from any photographic dealer are light, and one about a yard square will fold up into a very small compass, and can be easily carried in the pocket. In addition to this, a protective covering for the camera is ready to hand in the event of rain, which is a consideration in view of the present unsettled state of the weather.

The Focal Plane Shutter. The notable increase in actinic quality of the light during the past few weeks will tempt many possessors of focal-plane shutters to occasionally give the very brief exposures for which this type of shutter is specially adapted. An inspection of a batch of negatives recently taken by means of one of these shutters working at high speed has impressed upon us the necessity of keeping the edges of the slit in the blind free from abra-

sion of any kind. When a speed of, say, 1-800th or 1-1,000th of a second is given, an extremely narrow slit is employed. In the negatives mentioned, transparent lines appeared, stretching from top to bottom of the plate, that is, in the direction made by the passage of the shutter blind. These lines were most noticeable in the negatives which had received the shortest exposure, while in those cases where a fairly large slit had been used they were hardly visible. An examination of the shutter showed that abrasions on the edges of the slit were accountable for these lines. The material of the blind had been slightly torn, and a small tuft projected beyond the edge of the slit. The amount of light cut off by this little bit of fluff would be negligible when the blind was fairly open, but when the aperture was reduced to its smallest—about 1-16th of an inch—the parts of the slit where the pieces of fluff appeared were practically screened across, and allowed no light to pass during the passage of the blind across the plate. It will therefore be wise to carefully examine all focal-plane shutters for this possible cause of faulty negatives, and remedy it by the application of a small touch of adhesive, which should be allowed to thoroughly dry before winding up the shutter again.

* * *

The Amateur Question Again. At a recent meeting of the Manchester Amateur Photographic Society, an interesting discussion took place dealing with the question of placing prices to the photographic exhibits in the printed catalogue, issued at the annual exhibition of members' work, and its effect upon the status of the exhibitor as an amateur. Many diverse views were expressed, but the majority contended that where a demand arose for a copy or copies of a successful photograph, often obtained after much thought and expense, the producer was entitled to realise at least some reward for his ability and outlay, and that his position as an amateur was not forfeited thereby. In support of the argument, the custom of other graphic clubs, mostly composed of unprofessional workers, was advanced. This decision appears to fairly state the case, and in view of the fact that the proportion of sales at any photographic exhibition is usually very small indeed compared with the number of pictures exhibited, and that not many amateurs who exhibit at photographic exhibitions cover their out-of-pocket expenses by sales, we do not think that their status as amateur photographers is in any way endangered by a price appearing in the catalogue after their exhibits. The custom of putting a price on exhibition photographs appears to have arisen more from the desire to possess on the part of visitors to the exhibition than a desire to sell on the part of the photographer. A picture takes the fancy of a visitor, and he wants to buy it. The photographer cannot reasonably be asked to give it away, so a price is fixed, and in future exhibitions, to save the hon. sec. unnecessary trouble, the exhibitor is asked to place a price on his pictures beforehand. In any case, as

B

long as the photographer does not make his living by the sale of his photographs, we do not think he can rightly be altogether classed as a professional photographer.

Speed is Essential.

We are constantly coming in contact with black and white finishers who are seeking employment, and whose work possesses good qualities, but who are totally unable to grasp the fact that for such work to be remunerative speed as well as quality is necessary. A girl has had some training at one of the numerous schools of art, and can copy with fair accuracy a head in monochrome, or draw from the cast. She proposes to turn this ability to use, and learns the little tricks of working in the finishing of bromide enlargements. After some practice she can finish a few twelve-tens in a week, and expects to earn at least £1 a week. We recently heard of an inquiry for a finisher who was required to finish a hundred in a week. Of course this was cheap trade work, and not much can be done at a twelve-ten bromide in twenty minutes. The essential point is to know exactly what to do to produce the maximum of effect with the minimum of labour, and there is not time for a superfluous touch. The usual "pot-boiling" methods must be adopted—working, for instance, eight or ten backgrounds straight away with the air brush, and then doing what is necessary with the sable pencil afterwards. "This is not artistic work," says the aspirant for a post. Certainly not; but artistic work, except for the few with exceptional ability, means only a peg or two above starvation.

System and Tact.

Mainly owing to the misconceptions of many of those who have taken up professional photography, there is probably no other business with such a large proportion of workers who fail to systematise their work and methods. To begin with, there is always the difficulty with all artistic work of dissociating *business* and the *artistic element*. A few men of exceptional ability in certain quite unique positions may do well on their artistic skill alone. In the main, however, the second-rate photograph put before the public by the first-rate business man will mean a greater commercial success than the first-rate photograph handled by the man of small business ability. Some people—those, perhaps, who manufacture stuff in bulk and then distribute as orders come in to the warehouse—think of a "business-like man" as one who takes the sitter to-day and delivers the proof to-morrow, and who uses two plates instead of three so as to save twopence. Business ability may, of course, go much further than this. We should be the last to gainsay the value of promptness, but there are cases where too prompt a delivery is apt to disappoint the customer, and lead him or her to minimise the value of the work which has been done. We heard the other day of a ten-guinea miniature which was completed two days after the order was given, but which was put on one side and not delivered for a fortnight, because the lady who had placed the order would have thought ten guineas much too high a price to pay for work which could be done in two days. Human nature must always be reckoned with, and a system which produces cast-iron laws is not usually a success.

Tact in the Reception Room.

As we write the foregoing notes a copy of our contemporary the "Deutsche Photographen Zeitung" comes into our hands containing what professes to be the experiences of one of its staff in the reception-room of a fashionable photographer in the West End of London. There is a rustle of silks in the doorway, and an elegantly dressed woman enters, between whom and the photographer the following dialogue is reported to take place:—"You wish to make an appointment for a sitting, madam."

"If you please, for this afternoon, if possible."

"To-day, madam is impossible; we might say to-morrow before 11 o'clock. (To receptionist) What have we got for to-morrow? . . . At 11, madam, the Prince of D."

"It is too early. Suppose I say to-morrow at 2."

"Unfortunately, the Duke of P. has an appointment with us for that time."

"Well, I can come the following day at 10 o'clock."

"10 o'clock, the 17th, I have Mrs. N. at 10, and the Marquis of W. at 12."

Finally a sitting is arranged for some days later, and the lady departs communicatively gratified with her association through the photographer with a crowd of distinguished people. Now, does our German friend actually think that that is the sort of thing which any leading photographer in the West End will consider "good enough"? A number of studios are well-known to have distinguished patronage, and they are not likely to go out of their way to bait their hooks for the parvenu matron of the suburbs in the way we have quoted. And in the case of other studios which cannot boast the fashionable clientèle, it will need a more accomplished artist in "tact" than we take the managers for to give the necessary verisimilitude to the bald and unconvincing narrative.

Systematic Methods of Working.

It is possible in the actual manipulative details to follow system more rigidly. The methods of printing and mounting, for instance, may be reduced to a mere routine, just as many other manufacturing methods are. Even in the actual studio work of operating, the average photographer will produce his results with more certainty if he systematises his lighting, and, to a lesser degree, his posing. Few workers can light a head seen for the first time on the occasion of the sitting, by intuitive perception. It may be contended that any attempt to systematise artistic work will lead to a fatal uniformity, and will tend to stifle artistic feeling in the worker. We are not suggesting a method for the experienced operator who has been thoroughly trained and has had years of experience. But we are convinced that many workers who photograph sitters after sitters with little or no variation in lighting, or, on the other hand, who make variations without any regard to the type of face being lighted, will find great benefit from a classification of the various kinds of lighting. A few exposures may be made on two models—a full, round face with insignificant features, and a thin, ascetic face with prominent nose and deep-set eyes, the light being arranged as follows:—High side-light, low side-light, top light, front light, light at 45 deg. low, and light at 45 deg. high. The box of plates expended on this test will not be wasted by any means, and prints from the negatives will show very clearly the defects and advantages in each case. This is merely one of the many experiments which might be made. We would emphasise the need of each experiment being made with a definite end in view if the tests are to have any practical utility.

Fraudulent Canvassers.

In our last issue is a brief report of a charge against a photograph canvasser, who was remanded. Last week he was again brought up at the North London Police Court and sentenced to three weeks imprisonment. It was alleged by the police that other persons, mostly servants, had been victimised in similar fashion all over London, but they would not come forward to prosecute. Some little time back we called attention to the fact that a fraud was being largely practised in the suburbs of London as follows:—The canvasser calls at

houses with good specimens and a printed paper, representing that by buying from him for a small sum, sixpence or a shilling, a coupon, portraits will be taken at a certain studio at a much reduced price. The address of the studio is always a long way off. When the distance is objected to the victim is told that the portraits can be taken at a local studio, usually the best in the neighbourhood. When the dupe, dressed in her Sunday best, visits she learns that she has been victimised, and is sometimes hard to convince that the local photographer is not a party to the fraud. This, of course, is exceedingly annoying to him, and the worst part of it is that he is helpless in the matter, as he is not the party defrauded. It is those who have parted with their money, and they are, for the most part, poor servants, who cannot get the time to prosecute the offender even if they wished.

* * *

The Municipal-ised Thames. The inauguration of the London County Council's Thames steamboat service on Saturday last should mark the commencement of a new era for photographers of London's picturesque river. From Hammersmith to Greenwich is a long stretch, and in the ten or a dozen miles covered by the new service of steamers subjects galore for the land-camera man present themselves at every turn. This is particularly the case in that portion of the river below London Bridge, and known as "The Pool." Here are to be found hurrying past or swinging at their moorings, craft of every type and nationality, useful material all for pictorial compositions. Here, too, the atmospheric effects are always of the finest to be seen on any river in the country, if not in the world. They permit the realist to obtain ready made, by straightforward photography, results that surpass the strivings of the impressionistic worker who fakes his prints to approximate nature. Opportunities will also now be at the disposal of the photographer for more easily getting into the heart of that riverside London depicted by the facile pen of W. W. Jacobs. Convenient piers have been built at intervals of less than half a mile throughout the entire route, and are moreover conveniently placed on alternate sides of the river below Tower Bridge. The L.C.C. guide and map for use with the new service will prove very useful to the photographer, and we feel sure that an afternoon spent on one of the boats will not be a wasted one for the man with a camera.

* * *

The Ives Imitating Replicas. In further reference to the announcement a few weeks ago of a method devised by Mr. F. E. Ives for preparing replicas of diffraction gratings said to be less costly and less liable to shrinkage, it is now stated in the "Journal of the Franklin Institute," that the process adopted by Mr. Ives is as follows:—Casts are made from the rulings on speculum metal by covering with solution of soluble gun cotton in amyl acetate and allowing same to dry, after which they are stripped off under water, placed face down on plane glass and the water dried out under pressure, leaving the lines as air spaces between film and glass. They are then sealed up under another glass with a balsam mixture, thus protecting them from injury. Mr. Ives finds that these replicas are good enough for the most serious spectroscopic work, can be made at a comparatively low price, and may be handled freely by students in schools and colleges without risk of injury.

* * *

The Wisdom of Window Display. Dress your shop window smartly and put something in it to set people talking. You need not put very much, but it must be the kind of photography that the passer-by will stop to look at and appreciate. Such was part of the advice which

recent writers on photographers' advertising in these pages had to give, and an instance of publicity which a photographer gains by such a policy reaches us from Penzance. Messrs. Gibson and Sons, of that town, placed in their window certain seascapes, from which act probably they could trace no direct benefit. However, a photographic tourist, narrating his travels in a London suburban newspaper, writes thus:—"One of the finest effects of a sunrise which has ever been seen by the writer was in a photographer's window in Penzance. A whole holiday would not be wasted if it resulted in the securing of such a glorious result as 'Sunrise in Mount's Bay,'—a study which must make every amateur and professional envious. As a composition it is an excellent example. But the choice of the exact moment at which the scene was captured speaks volumes for the ability of the man with the camera. No photographic visitor to Penzance should miss seeing Gibson's window, where another charming picture is the entering of Penzance harbour by a Scilly Isles mail boat during a storm." All of which is a good advertisement for Messrs. Gibson, and will no doubt bring London visitors who see the paragraph to their studio. It is Messrs. Gibson's fault if such references to their work does not advantage them in their business, and it is every photographer's fault if he neglects opportunities such as these of making his work favourably known.

A BUSINESS QUESTION.

IN our correspondence columns this week Mr. F. M. Sutcliffe protests against a state of things which he regards as a widespread source of loss to photographers, and one which, so he appears to think, the photographer may seek to redress by the copyright law. Says Mr. Sutcliffe:—"Some smart person, who comes to be photographed, gets proofs, says they are horrible, has the proofs copied by some cheap firm, and does one or other of us out of our guineas." It is a mean action, but one, nevertheless, which may be done in some instances, as proved by our correspondent's experience, but that it is at all general we are inclined to question. There is no doubt that proofs only are sometimes paid for, and then are reproduced at a cheap rate by copyists, or perhaps by amateur friends of the sitter's. This appears to be the writer's grievance, but upon looking at the matter from a business point of view it will be seen that the grievance is more imaginary than real. If the proofs are kept and not paid for, the photographer has a remedy in the County Court, by suing for their value, according to his price list. If the proofs have been dealt with in the way our correspondent says there could be no defence to the action, as the pictures, which the sitter stated to be "horrible," were not so, or he would not pay to have them reproduced. The photographer would obtain his money, and the defendant would be mulcted in the cost, in the same way as any other tradesman would recover for "goods sold and delivered." Some photographers have had the courage, not "foolishness," to take action, and have recovered their money. Mr. Sutcliffe complains that, "Not only do people have cheap copies made from proofs supplied them, but they often have enlargements done from photographs which they pretend they do not think good enough to order from." But have they not a perfect right to do so? They have—if the proofs were paid for; if not, the photographer can recover the value of them in the County Court. Surely a person has a right to do as he likes with his own? It is certainly very annoying for a photographer to find that his pictures have been reproduced at a cheaper rate than he would supply duplicates for, or perhaps see enlargements made from them at a much lower price than he would charge; but, after all, he has not so

much to complain of, seeing that he has been paid for what he has done, and there the matter ends so far as he is concerned. He has no copyright in the portraits he has been paid for taking. The copyright in them belongs to the customer.

If a photographer invites a person to sit, and does not charge for the sitting, the copyright belongs to the photographer; it is his property. But if a sitter goes to him to be taken in the ordinary course of business, even if he does not pay, the photographer has no copyright in the picture—that is vested in the sitter, though it remains to be proved whether the customer can register a copyright when he has not actually given valuable consideration for the taking of the photograph. We may here quote a case in point—*Boucas v. Cooke*, which was tried before Mr. Justice Ridley in 1902.

Briefly the case was this: The defendant went to a photographer (plaintiff) to have his portrait taken, and said that he would buy the negative if he liked it. No money passed. Some copies were supplied, but the parties did not agree as to terms, and the defendant had copies made from one of the prints, and published them. The plaintiff then registered the copyright, and commenced an action for infringement, claiming penalties and damages, and the court awarded both. This judgment, however, was taken by the defendant to the Court of Appeal, and came before the Master of the Rolls, Lord Justice Stirling, and Lord Justice Mathew, who allowed the appeal, thus reversing the judgment of the court below. The Master of the Rolls, in delivering judgment, said the question, then, was not whether the negative was bought or sold, but whether it

was taken for or on behalf of the sitter for a good and valuable consideration. Upon that question the evidence appeared to be all one way. A person came to the shop and asked to have his portrait taken. Obviously there was an implied promise to pay for it, upon which the photographer could sue the sitter. Obviously there was, therefore, a good and valuable consideration. The appeal, as we have just said, was allowed, and judgment was entered for the defendant with costs. A report of this appeal will be found on pp. 392-3 of our volume for 1903.

Mr. Sutcliffe asks: "Is it not time it was decided that the money value of 'good' or 'valuable' consideration was fixed?" One would have thought he would have known that this was fixed by every photographer when he arranged his price list. Whatever he is paid for taking a portrait, whether much or little, is a good or valuable consideration. If a photographer takes a portrait for half-a-crown, or less, he receives a good or valuable consideration for his work, just the same as if he charged £5 or £10 for it, at least, in the eyes of the law. He is the appraiser of the value of his work. The postscript of the letter is somewhat amusing, when he asks: "Would it not be possible for us to put into our price lists, that unless we were paid £5 to £10, we retain the copyrights." One would have imagined that he would be fully aware that whatever price, small or large, he was paid, the copyright was the property of the sitter and that it could only become the property of the photographer by the customer assigning it to him, and that that must be done in writing. We have dealt with this subject at some length, as some of our readers, like our correspondent, possibly may not have read what has appeared on the subject in our pages during the past year or two.

THE WEEK IN HISTORY.

Photography on Paper in France.

DESPITE the immense furore which Daguerreotype aroused in the land of its birth, it is worth while recalling that no sooner had Talbot's entirely different kind of photography been made known than there were workers in Paris who took up this process with avidity, doubtless seeing in it the germ of endless methods to which the single-picture method of Daguerre was not amenable. Thus it was almost exactly 66 years ago—on June 24, 1839—that an exhibition of paper prints was opened in the "Salles des Commissaires-priseurs" in Paris. In fact, this exhibition was held more than a month before the actual process employed by Daguerre was made known to the public. Bayard was the man by whom this collection was brought together, and his name might well be coupled, though in a minor key, with those of Talbot and the French inventors.

From Niépceotype to Daguerreotype.

Daguerre, in his book upon his invention, was at some pains to point out the entire originality of the process which bore his name, but the correspondence between himself and Niépce during the last year or two of the latter's life bears another interpretation. It is certainly evident that Daguerre was "put on to" iodide of silver by Niépce, who, however, did not use it as the sensitive substance in his process, but as a means of blackening what should have been the dark parts of his subject, but which by his process were represented by bare silver. Thus we find Niépce writing to Daguerre on June 24, 1831, as follows:—" . . . being occupied with the experiments on iodine, I am anxious to let you know the results. Before our partnership, I had made experiments, but without hope of success, as I saw no means of fixing the images, even when the light and shadows had been recorded correctly. . . . However, since you left here I have made another set of experiments, using iodine in a different way.

Your reply when I acquainted you with the results convinced me of the inadvisability of doing more in that direction."

Warnerke's Negative Film and Roll-holder.

Paper for glass, and a pair of rollers on which to wind it, formed the text of Leon Warnerke's argument for tourists' photography exactly thirty years ago. In *THE BRITISH JOURNAL OF PHOTOGRAPHY* of June 25, 1875, he explains the making of his negative paper and the design of his "dark slide." White enamelled paper was coated twice with collodion containing a little paraffin, and twice with a thin rubber solution—these applications being alternated—and finally with gelatine or washed collodion emulsion. This film was stripped from the paper and attached to a glass plate before development. The "dark slide" was similar to those I have already referred to in these notes. It contained space for a hundred exposures, and was provided with an orange window by which the operator could observe the passage of the pencil lines which marked the separation of the different sections. Warnerke's prophecy has been immeasurably exceeded. "Who can dream," he asked, "with the glass system, when going to distant lands, of taking one thousand plates for his long excursion? But with my film that number, or one still larger would not increase the weight of the traveller's luggage by more than a few ounces, and by a few inches the space occupied."

The Ferrous-Oxalate Developer.

It is now eight-and-twenty years since the iron developer was introduced by Carey Lea—to be precise, in *THE BRITISH JOURNAL OF PHOTOGRAPHY* for June 29, 1877. It was advocated by him as a developer of paper (paper negatives), and he gave directions for the two methods of preparing, viz., by solution of precipitated ferrous-oxalate in potassium oxalate solution, or addition of ferrous sulphate to a strong solution of the oxalate.

HISTORICAL.

THE OPTICAL CONVENTION.

The following paper by Lord Rayleigh on the "Polishing of Glass Surfaces" was delivered before the Optical Convention on June 1.

The text printed below is from a shorthand report, revised by Lord Rayleigh.

POLISHING OF GLASS SURFACES.

What I have to bring before the Convention is not absolutely new, or I have already used some of the material at the Royal Institution,* but I do not think the remarks I then made attracted very wide attention, and I was wishful to bring the matter before a meeting like this where there are present so many, not merely theoretically, but practically, conversant with optics, and the more so as some conclusions which I have put forward appear to stand in need of confirmation, or, perhaps, of correction. From a theoretical point of view there is no great difficulty in treating the question of polish. We may consider the standard surface to be a corrugated one, and corrugated in a regular manner, and we may inquire how the reflection of light—or sound, for that matter—is affected by the corrugations, how far the reflections differ from what they would be supposing the surface were absolutely plane. Here the question assumes a specially simple form if we limit ourselves to the case in which the medium is impenetrable to the vibration. In other words, acts as a perfect reflector. In the case of light, we may think of silver as representing a perfect reflector. In the case of sound, almost any solid or liquid body with a continuous surface plays a similar part. Consider then a corrugated surface bounding a material having complete reflecting power, and we shall then find that the question turns entirely upon the relationship between the period, as I will call it, of the corrugation—the distance from ridge to ridge along the surface—and the wave-length of the vibration that is being reflected.

This question was considered long ago by Fraunhofer in connection with gratings; and, I may remark parenthetically, that it seems to me he has never really had full credit for his work in this direction. We well know the effect upon light incident perpendicularly when the lines of a grating are closer together than a wave-length of light. The spectra that would be formed with a grating less closely ruled are, as it were, pushed out of the field and nothing of them is left. It was upon this that Fraunhofer founded a conclusion as to the limits of microscopic power, and to my mind his argument was perfectly sound, as well as his conclusion, if we make a slight correction in it. Fraunhofer, I think, did not quite correctly treat the case of oblique incidence. And we know from the ordinary theory of gratings that if the light is oblique the last spectrum does not disappear until the distance between the lines, the period of corrugation, is as small as half a wave length, so that there has to be a greater degree of closeness if obliquity is admitted.

What is Polish?

Taking, then, the case in which the medium itself is perfectly reflecting, if there are no diffraction spectra formed, it follows at once that the whole of the light must be concentrated in the beam specially reflected, and thus the corrugation has no effect whatever. The surface, however deeply corrugated, is perfectly polished; no light can depart from it in any false direction. From that we may obtain a very good general idea of what is necessary in order that a surface generally should appear polished, although the simplicity of the two dimensional cases will be somewhat departed from. It is all a question of the relation to the wave length. If we are dealing with sound, where wave lengths are comparatively long, then a very rough surface indeed is sufficiently polished to act as a perfect reflector. In fact, we might artificially roughen a surface with attached pebbles, and yet leave it smooth enough to act as a perfect reflector for sounds belonging to the middle region of the musical scale, and the reflection would be as complete as if the surface were mathematically smooth. The pebbles would not act as a defect of polish.

Wave Length and Polish.

But when we come to light, of course, the case is very different. But even here it is a question of what kind of light we are speaking of. A surface may be fairly well polished for red light and fail most decidedly if we use it for the reflection of blue light, or for the more especially blue rays beyond the blue. A surface that would be very imperfectly polished for those rays which affect the eye may be practically well polished for the dark heat rays which are found in the spectrum beyond the red. In fact, I once made an experiment in which I used a ground glass not polished at all, silvered over the roughnesses, and reflected with it the light from a Welsbach mantle used without a chimney. I found that in that way I could get a very good approach to complete "specular reflection" for dark radiation from a surface that would not count as a polished surface at all. The test was made with a thermopile.

Polishing and Grinding.

I need not explain to such a meeting as this what are the practical processes of grinding and polishing glass, but I wish to raise a ques-

tion as to the difference there may be between the two operations. Herschel, than whom in his day there was no greater authority, held the view that the polishing operation and the grinding operation were of one and the same character; that in the grinding—I am speaking of working a hard surface—lumps of glass were broken out by the emery with which the glass was brought into close contact under pressure, and that in the polishing a similar operation was still going on, although on a much smaller scale.

The Mechanics of Polishing.

Herschel expressed surprise that it is possible at all by means of art to reach a surface that shall be polished according to the necessary standard, that standard being set by the wave length of visible light. My own observations upon grinding and polishing glass led me to rather a different view. It appeared to me that the operation of polishing as conducted with rouge embedded in pitch or carried upon a softer material, like cloth or paper, was of essentially a different kind from the operation of grinding. I followed the process under the microscope, which is easily done, especially if the surface is smeared over with a little aniline dye. It appeared that under the polishing no visible pieces of glass are broken away at all. The polishing begins naturally upon the eminences left by the grinding, and in a very few minutes it produces little facets on the top of those eminences, and these soon reach a size sufficient to allow of a certain degree of regular reflection. After five minutes' polishing of a ground surface I found it quite possible to observe interference rings between the very slightly polished glass and a flat and fully-polished one brought into juxtaposition with it. As the polishing proceeds, the area of the facets increases, and new ones are developed; but the point I wish to emphasise is that there is no progress in the polishing. The polish is perfect, where it exists, from the very first.

A Molecular Process.

So long as the area of the facet was visible at all under the microscope, I was never able to see any structure in it. It appears that the progress of the polishing consists only in extending the area of the polished surface, but not at all in improving the polish in any part that has been once polished. In that case we must take a different view from Herschel as to the character of the process. We can no longer suppose that pieces are broken out under the polishing analogously to what happens in the grinding. It seems to me rather that the process is a molecular one, or nearly a molecular one, the upper layer of molecules probably being operated upon by the polishing material. That structure cannot be seen under the microscope is no proof that there is, in fact, no structure until we come to the molecular limit; but the impression produced upon me was that the two processes were so discontinuous that it was a very natural conclusion that in the polishing process the material was acted on molecularly. That is one of the points which I wish particularly to raise, because I am not a practised microscopist, and the observation is one that can be easily made by any one who is accustomed to work glass, and the question seems to me an important one that should be definitely settled.

Polishing Soft Materials.

In what I have said it will be understood that I have been speaking only of hard material. Mr. Beilby has made very interesting observations upon the polishing of softer materials, such as metals, and he holds that in that case the polishing process consists not merely in removing the eminences—the parts which are protuberant—but in filling up the pits with the material removed from the eminences. In that way it is easy to understand that a very much more rapid approach to uniformity would be obtained; but I must say that in my experience with glass—and my experience was limited to glass—I never saw anything to suggest that idea, and my impression is that no material once moved is deposited again, and that the process of polishing has to be continued until all the glass is worn down to the level of the deepest pits.

Polish and Optical Performance.

I have a slide here, made under the microscope, of a piece of glass examined towards the latter part of the process of polishing. The pits are shown dark, and between the pits there is no structure to be seen. These parts are entirely polished. From the amateur's point of view, the polishing may often be terminated at a much earlier stage than would commend itself to a professional optician. I have made lenses which work very well for my purpose, although certainly one would complain if anything of the sort were supplied to one professionally, but I have never been able to see that their performance was any worse. The parts not polished are a very

* "Proc. Royal Inst.," xvi. (p. 563), 1901. Scientific Papers IV. (p. 542).

small part of the whole, and if it is a question only of the amount of light, I do not suppose that the quantity dispersed by the spots would be missed. It might be another matter if it were a question of getting a very dark field for seeing a faint object. I am not suggesting that telescope glasses should not be properly polished, but pointing out that in many cases a very inferior polish suffices. Of course, I only speak as an amateur. In that way not only is the process very much quicker, but there is also less danger of losing the figure of the surface, which is, I think, usually accurate enough at the termination of the grinding, but which is liable to be lost in the process of polishing.

Loss of Material in Polishing.

As to the amount of material that has to be removed in the polishing of glass, I made some observations. Some were made by weighing the glass to find out how much material it had lost during the operation. I started with a very finely-ground surface, rather more finely ground, I think, than is usual in practice, and I found that in order to obtain a pretty good polish it was necessary to remove a weight of glass, corresponding to a depth of about six wave lengths. I do not pretend that such a polish would satisfy the requirements of commerce; probably the six would have to be raised to ten or twelve in order to get down to the bottom of the deepest pits.

In another case I used a disc of glass, very finely ground and polished, in the lathe in rings, the object being to obtain a gradually improving polish over a finite width, increasing from the margin, where very little polishing was done, to the centre of the annulus, where the polishing would be at its best. When these rings were examined under the microscope it was found there were very few pits left in the middle of the ring, and I was able to obtain the result, easily verified by forming interference rings between this and another flat glass, by removal of material to a depth of only two or three wave lengths. I have one or two slides in which bands are shown obtained in this kind of way. This first was from a glass sold to me as a "flat," and it was combined with another which was at any rate much better than itself. The rings were formed with sodium light, and the photograph was taken upon a plate sensitised with cyanine. Although the figure of the glass was not bad from the point of view of general sphericity the spherical surface was very far indeed removed from the plane. This next slide is from a piece of ordinary plate glass, in which the surface is saddle-shape, therefore hyperbolic, showing bands. Observations of this sort are very easy, and it is not difficult to obtain the photographs.

Action of Hydrofluoric Acid on Glass.

I may mention that I made, in connection with this subject, some curious observations upon the effect of treating glass surfaces with hydrofluoric acid. The acid was very dilute, the commercial acid

diluted perhaps 200 times and kept in rapid motion in a bath. I found that, so used, the acid acted much more regularly than I had expected, or I believe would be generally expected, and it was perfectly possible to eat away the surface in a regular manner to any required small depth—such as half a wave length. I was able in that way to prepare rather pretty patterns by etching two flat surfaces in strips and afterwards combining them crosswise, the depths being so chosen as to give the most brilliant colours of Newton's rings. I have a slide which shows the effect of contact with a drop of very weak hydrofluoric acid. This plate had been subjected to various experiments such as longitudinal polishing, but you will see the place where the drop of acid has stood for a few minutes, having the appearance of a hump. It is really a depression in the original glass, and by counting the bands one can see what the amount of depression was; it is about two bands, which would mean one complete wave of sodium light. In those cases we start with glass originally polished. Some very curious observations were also made upon the effect of hydrofluoric acid upon glass originally finely ground. The acid acts in such a way as to eliminate from the roughened surface all the finer irregularities, leaving only those of longer periodicity.

It is not difficult to form a theory and to illustrate that theory by drawing, especially if one takes the case of two dimensions. If one assumes, as seems reasonable, that the hydrofluoric acid acts, then the envelope of all those surfaces will be the surface to be expected at the close of the operation. You see the ultimate result will be to leave the surface in the form of spherical segments, the centre of the sphere corresponding to the deepest places in the original roughly ground surface. I have a slide showing the appearance of such a piece of ground glass after treatment. It appears to be divided into a number of cells, and the wall by which each spherical segment is separated from its neighbour is of the nature of a ridge. Each cell is itself absolutely devoid of structure; it appears finely polished. Although the surface was originally finely ground all over, all the finer irregularities are gone, and we are left with the surface, which in a sense might be called polished, although, of course, it is far from flat. In each case, if we are looking down upon the surface, the middle of these segments will be the deepest place; the ridges are raised and exceedingly sharp. According to the theory I have briefly sketched, they would be mathematically sharp, and such they appear to be. The character of the surface so obtained is illustrated by another photograph, made with a slightly different focus of the microscope. The light comes from a paraffin lamp across which two wires are stretched. Under the focus adopted each of these spherical segments acts as a concave lens. The focus is not the same for all, but they give material for calculating what the concavity was in each case. I found I could make a very good estimate of the exact shape and size of the various cavities.

RAYLEIGH.

REMINISCENCES OF THE DUBLIN CONVENTION OF 1894.

III.

On the Road to Monasterboice.

I am not quite sure, but I think the excursion originally arranged for Tuesday took place on Thursday, and *vice versa*, but like all things in Ireland it came out all right in the end; at any rate, we went to Drogheda, the Valley of the Boyne, Monasterboice, and Mellifont.

The most inconvenient part of this excursion was, that it was impossible to arrange for lunch until our return to Drogheda at 4 o'clock. Many of us had risen early, we had not all had time for a good breakfast, so by the time we were well on the road to Monasterboice there was an aching void. Passing through one of the villages we came across the local "Stores." One car pulled up, then another, then a third. Soon the little shop was raided, everything in the way of biscuits, bread and butter, lemonade, and ginger beer was entirely cleared out in about a quarter of an hour, and a small army of ladies and gentlemen with a snack in one hand and a bottle or glass in the other, could be seen occupying the entire roadway—very informal, not dignified, but very jolly, and the remainder of the drive was enjoyed all the more by those who thus satisfied the vacuum so abhorred by nature.

We wondered at the time why three of the cars did not pull up, but heard afterwards that some of the wives in this party, with that foresight which characterises the sex (bless 'em), had provided

sandwiches and a flask, the contents of which they quietly enjoyed at the end of their drive.

[We are going the same journey again this year—thoughtful wives please copy.—Eds., B.J.P.]

Jaunting Cars.

Riding in jaunting cars requires a certain amount of practice. During the first two or three days several members had complained of having grazed their shins, and having been sorely tempted to use language stronger than they found necessary under normal conditions. There are inside and outside cars, the difference being that the inside cars have the wheels outside, and the outside cars have the wheels inside. The latter are more difficult to get on, and keep on than the former. On the previous Monday, by the bye, two of our members, when the car was rounding a sharp corner, were landed in a prayerful attitude on the pathway, and some of the remarks made by the passers-by were anything but sympathetic.

By Wednesday, however, we were getting more accustomed to the tricks of these vehicles, and not only mounted them gracefully, but were able to remain on them with a fair amount of confidence.

Convention Functions.

The garden party given by the Lord Mayor and Lady Mayoress at Killiney in the afternoon, was most enjoyable. A hearty welcome

mid splendid surroundings, a good band, and fine weather all contributed to make this one of the most pleasant functions held during the meeting.

In the evening came the annual dinner, the best part of which was unquestionably the speeches. The menu was excellent—menu's generally are—but a good dinner on paper, however elaborately printed, is not satisfying. Our good friends had evidently been the victims of misplaced confidence in their caterer, so we took the will for the deed, and drank the toasts with enthusiasm.

Incidental Advantages.

I think we had more ladies at Dublin than at any previous meeting, and since that time the number has greatly increased. It is now become quite usual for members to bring their wives and sisters. The result in many cases being that acquaintances have been made which have ended in the wearing of orange blossoms. In fact only last year, I believe, one more young lady agreed to sacrifice herself on the altar of cake and cards, give up single blessedness and "indulge in the felicity of connubial domesticity."

The Dargle.

On Friday, a most enjoyable excursion to the Dargle, Powerscourt, and Bray. The Dargle, very beautiful, Powerscourt internally and externally very interesting, and Bray (the Brighton of Ireland) very breezy and refreshing. At Powerscourt we lunched on the grass, and had scarcely finished when a heavy shower came on. Most of the eatables had been cleared away either by the members or the caterer, but the tablecloths would have at any rate to be dried and mangled before being used again.

The excursion on Saturday was to Glendalough and the Seven Churches. Train, jaunting cars, and a most enjoyable drive, despite the showers.

Perhaps the first thing that occurs to most people when visiting this interesting and beautiful valley, are the lines:—

"By that lake whose gloomy shore,
Skylark never warbles o'er."

and all sorts of stories are told in explanation of this, the most popular, being, that the workmen when building the Seven Churches used to be aroused to their labours by the skylarks, but when the work was over and all the churches were built, the good St. Kevin forbade any more skylarks to follow the pious birds who had rendered such services to the good cause of religion. In connection with this it has been stated that one day an Irishman went to

confess, and taking a sparrow from his pocket, for fun, threw it up near St. Kevin. "Now, Pat," said the wily saint, "none of your larks"; and this is said to be the origin of the well-known phrase.

The most interesting building in the valley is perhaps the one called St. Kevin's Kitchen, so named because the peasantry mistook the round tower for a chimney.

I believe, on the occasion of our visit, some professor kindly promised to give an address on the archaeological remains in the neighbourhood. Whether he did so or not I do not know, but I did not hear it. To do a thing of this kind at a Convention excursion is very good-natured, but I am afraid is not appreciated as it should be, and it is rather unfair to a learned gentleman to ask him to take up much valuable time which might be utilised in photography, and occupy perhaps the centre of the photographable area for the purpose of explaining something which might or might not have happened 500 years ago.

I mentioned the showers which occasionally interrupted our photography on this occasion. While standing up during one of these I watched for some time a man fishing in the lake. I did not happen to see him catch anything, so said to a native standing near:—

"Are there any fish in the lake?"

"Fish is it! Why, sure in some parts there's more fish than water."

"But that gentleman does not seem to be catching much."

"No, sorr; not now."

"What do you mean by not now?"

"Why ye see, sorr, he's been staying up at the hotel for the last three weeks, fishing all the time, and the artful devils are getting to know him."

Saturday evening saw some of us reluctantly quitting the "Green Isle of Erin," as the Convention practically came to a close with the Glendalough excursion. Some lucky ones were able to stay another week and visit Killarney, Cork, and Bantry, Blarney, and Glengariff. There was only one opinion about the success of the meeting, we had had glorious time in the "distressful country," and its people had done their best to make our visit enjoyable, and fill us with an earnest desire to renew their acquaintance at the earliest opportunity. Eleven years have passed since that time, a few of those members who then shone so prominently have unfortunately gone to join the greatest of all Conventions, but many, thank God, still remain, and are looking forward with pleasant anticipation to the forthcoming meeting.

F. A. BRIDGE.

ON THE REPRESENTATION OF MOVEMENT BY ART AND BY PHOTOGRAPHY.

II.

Raphael's Method.

"RAPHAEL always left around his figures the space necessary to indicate the position in which they were at the moment immediately preceding that chosen for the theme of the picture. He was careful not to fill up the void which in their movement would be left behind them. We here see how it is that Raphael succeeded in giving to his figures that spontaneity of movement and that true and serious grace which leaves an impression so powerful upon intelligent and sensitive minds. Instances may likewise be selected from the works of Titian, the great Venetian painter, in which the expression of movement and animation is portrayed in a wonderful manner. In a small painting, representing Christ appearing to Mary in the Garden, the Magdalen seems fairly to run forward to meet the Lord, her hair streaming and her drapery denoting the utmost rapidity of action, while the hand stretched forth to touch Him is suddenly checked by His words: 'Touch me not.'

Photography and Suggestion of Motion.

It is not pretended that photography will ever aspire to enter the province of imaginative art. With all its vaulting ambition it has never presumed to 'o'erleap itself'; but this shut door does not prevent or debar it altogether an entrance to the temple of art. We believe it has, and will continue to produce, pictures which stimulate the beholder to create mentally something which is not actually before the eyes in the theme it undertakes to represent. That is, it may in a measure be suggestive and bear strong marks of the individuality of the photographic artist, of his permanent personality, and of the more or less accidental impression produced upon him by the sight of the object before his vision.

One of the methods of rendering a photographic picture suggestive is dependent upon the manner in which the idea of motion or movement is conveyed, in which instantaneity, so-called, has no part or lot. By a scrupulous adherence to actuality in movement it takes

away the very appearance of reality, motion, life, action, because it represents the object as if it were petrified in the transient state, fixed constantly in a position which could not be preserved for more than an instant without pain. How insupportable do those statues of heroes become as we behold them upon their solitary pedestals with arms extended, for ever holding that uplifted sword. We look for some indication of what has immediately gone before, and also something of what is about to follow. It is only thus that a figure simulating movement can have full truth and power of expression. The artist, painter, or photographer must ignore, in some measure at least, the extremely narrow limits of the single attitude. This lack of the impression of a continuity of movement is particularly felt when reviewing some of our statues of military heroes.

Sculpture and Motion.

I recall a photograph of a group by the French sculptor Paul Baudry in the foyer of the Paris Opera House. Notwithstanding the violent simulation of motion in outstretched legs and arms, there is conveyed only the impression of an unpleasant immobility. The group is a representation of what a snapshot would give of a similar congregation. It presents purely arrested motion, there is no co-ordination to a general movement, which the mind itself should supply. All the movements do not trend to the idea of one impression. We

have spoken above of the petrified military heroic statue, and of its immobility giving an unpleasant impression, but let us place the same military hero, with uplifted sword and his steed with elevated legs, in fact, in the precise sculptured attitude, in a painting marching at the head of a victorious host with streaming banners, and the mind of the beholder has something to turn to for relief, to refer the attitude to the violent movement, and at once the impression becomes strong and full of meaning.

Association of Ideas.

It might be well, therefore, for the photographer to follow the method of the painter when desirous of conveying the idea of movement, and not to endeavour to seek the representation of action in transient attitudes. A transient attitude may indeed be depicted, but not isolated from its connection with the associated motive, so that the mind weary not of the perpetual sameness.

By association of a special phase in the movement the photographic artist might give an intensity and energy of action to a picture which the isolation would find very difficult if not impossible to support. The figures introduced in a photographic study should be surrounded by that which is needed to explain them, so as to show their relation to the rest of the work."

JOHN BARTLETT.

THE COPYRIGHT UNION.

SOMEWHAT belated, the report of the tenth annual meeting of the Copyright Union has reached our table in the shape of "Copyright Notes," No. 2, an occasional paper issued by the Union, and, presumably obtainable from the secretary, 23, Soho Square, London, W. We could wish that it was superfluous for us to refer to the work of the Copyright Union; but the steady stream of queries on copyright matters which flows upon us week by week supplies proof positive of the ignorance, in the minds of a large proportion of the profession, of the very existence and objects of the Union. Wherefore it seems all the more expedient to set out in full the work which the Union is constantly and silently doing for its members, and to impress upon photographers the benefits to themselves and to the photographic community by enrolling their names on the Union's list of members. We now quote from the report such passages as will explain the scope and influence of the Copyright Union's labours.

Mr. Alfred Ellis, in the absence of Mr. Frank Bishop (president) announced that over 400 letters had been received and had attention during the year; also that 133 photographs had been registered on behalf of members. Two members whose copyright photographs had been reproduced in France, received substantial sums through the assistance of the Union.

Two members, one in Portuguese East Africa and the other in Mombassa, British East Africa, had been paid fees for reproductions of their work through the Union. Another member in Scotland, whose work had been reproduced as postcards, recovered through the Union an adequate amount in compensation, and the delivery up of some thousands of postcard infringements.

Correspondence from New Zealand, Cape Town, and Sydney had been received, asking for advice re Copyright Law in photographs, which was under consideration in those colonies, and in each instance it was strongly urged that reciprocity should be extended to English photographers.

The Secretary's Diary.

The following extracts from the Secretary's Diary will help to illustrate the extent of the Union's influence, and how members as well as non-members look to it as the strong friend to appeal to in time of need.

1. A photographer in Trinidad sends replies to queries re infringement of copyright.

2. A photographer in Africa asks assistance in arranging fees for the reproduction of his photographs.

3. Photographer asks for information as to protection of copyright photographs in America.

4. Member asks query as to piracy of photographs in the United States.

5. Member sends letter from publishers asking for advice, etc., re fees.

6. Member sends particulars of an alleged infringement.

7. Firm sends cheque in payment of fees for right of reproduction of a Colonial member's photographs.

8. A correspondent in Australia asks for suggestions for a Copyright Bill.

9. Photographer asks for advice as to using old subjects copied 20 years ago for customer.

10. A photographer in the West Indies sends particulars of reproductions made without permission in Canada.

11. Member in Portuguese East Africa sends photographs for registration.

12. French photographer asks for information in a press agency.

13. Members ask for particulars of registration in Canada and U.S.A.

14. Bureau International, Switzerland, asks for copies of pamphlets issued by the Union.

15. A member asks for information as to royalties on postcards.

16. Member in India asks for the arranging of fees for the right of reproduction of their copyright photographs.

17. Member in Lourenco Marques asks Union to apply for compensation for the use of their copyright photographs in a steamship company's handbook, which was obtained.

18. Member asks for advice re charges for reproduction of his photographs as letter cards.

19. Member sends particulars of infringements as postcards, which was eventually settled by payment of adequate compensation and costs, and delivery up of some thousands of infringements.

20. Member draws attention to infringements of copyright in

rench illustrated paper, which was settled by payment by compensation and notice in subsequent issue

21. Australian member sends book of photographs for registration.
22. Photographer in India wishes to become a member, and sends photographs for registration.

Advice from the Union.

A Book to Get and to Read.—We have been much interested in reading a most valuable handbook, published by Messrs. Dawbarn and Ward, Limited, entitled:—"Photography for the Press," and we can confidently recommend it to our readers as possessing much good and reliable advice. The price is 1s., and the publishers' address is 6, Farringdon Avenue, London, E.C.

An Important Point.—Will our members be careful in emphasising the fact that there is no usual fee of 10s. 6d., but that it is only the minimum allowed by the Union, members being justified in charging whatever amount they deem necessary and expedient for the use of their valuable property.

How to Fill in the Registration Form.—By the courtesy of the secretary of the P.P.A. we are enabled to give the following extract from their handbook, No. 5, regarding this most important point:—

"The form is divided into five spaces. In the first, under the heading 'Description of work,' the picture should be fully described, commencing with the words 'Photograph of.' Example: 'Photograph of Mrs. Wm. Wiggins, from $\frac{1}{4}$ -plate negative. No. 16,504, $\frac{1}{4}$ -length standing, full-face, holding hat."

"The filling-in of the fourth column is obvious from its heading:

'Name and place of abode of proprietor of copyright.' The name of the firm or company should be given as proprietors, but the signature to the form in the case of a firm consisting of two or more partners, must be signed by one of the partners with the usual signature of the firm, that is to say not by one of the employees, and in the case of a limited company either by the secretary or one of the directors.

"In the fifth column—Name and place of abode of author of work"—if the proprietor himself took the photograph the information in the fourth column must be repeated. If the photograph was taken by an assistant, the name of the assistant and his residential address must be inserted.

"The second and third columns are only for use when a copyright is transferred or assigned from one person to another, and should be left blank in the ordinary simple registration of copyright.

"A copy of the photograph should be attached to the back of the form.

"With regard to the question of stamping forms of agreement of transfer or assignment of copyright, these should be stamped to make them a legal document, a 6d. stamp if the consideration paid is not more than £10."

More Members Wanted.—Are our existing members doing their duty by inducing brother photographers to join? There are always occasions when the strict adherence to Rule 23 is difficult, but when the welfare of the whole body is at stake—we must bear each other's burdens. The secretary of the P.C.U. can always be communicated with at 23, Soho Square, London, W.

THE CHILD AND THE CAMERA.

AN interesting article on the methods of Mr. Richard Speaight, the well-known children's photographer, has appeared in a recent issue of "The Daily Mail." The writer comments on the fact that children are in great demand as bridesmaids, pages, stallkeepers at bazaars, flower and programme sellers at charity entertainments and hosts of other functions, and as each occasion means the wearing of a new costume, sometimes modern, sometimes historical, a visit to the photographer generally follows; and thus it is by no means an uncommon occurrence for the children of fashionable parents to be taken as many as ten times during the season, from the beginning of May to the end of July.

However, in the presence of strangers, children are apt to be self-conscious or nervous, and, therefore, in order to obtain natural pictures the photographer has perforce to make use of all sorts of wiles in order to get a snap at a time when the youngster is posed before the camera.

The Camera in the Nursery.

To get quite fine results it would seem advisable that the little ones should not know they are being taken. Mr. Speaight, therefore, has frequently taken a child from another room. This is done by placing the camera in the nursery or wherever it is wished to get a characteristic picture, and then connecting it with a tube or bulb outside. In a few minutes the child forgets all about the camera, and then, when a favourable opportunity presents itself, the photographer, peeping through a crack in the door or some specially-made "loophole," presses the bulb, and the operation is over.

Child Photography at Home.

Time was when it was usual for children to pay a visit to the photographer to be taken; to-day, however, in many cases parents prefer to have their children taken at home, as there it is easier to get a natural picture. On one occasion a lady well known in society wrote to Mr. Speaight that she wished him to take a photograph of her children playing in the garden. They, however, were not to

know that they were being photographed, as she particularly wished that they should not be taken "posing" or in self-conscious attitudes. Accordingly, the photographer went down to the country, where the children were living, but after several visits found that it was quite impossible to take a "snapshot," as someone had confided to the children that a "photographer from London had come down to take them." Ever afterwards, therefore, they were on their guard, and took the greatest delight in thwarting the photographer's efforts to take them at play. In the end, however, the youngsters lost the day. The juvenile defeat came about in this way. In a corner of the garden there was a huge summer-house, overhung with trees, and facing the lawn. One morning after breakfast the patient knight of the camera took up his stand behind this useful shelter, and, hidden from view, succeeded in getting some admirable photographs. On learning that the pictures had been taken, the youngest child, a little girl of six, tearfully declared that "this was a nasty, mean way of doing things, and that instead of having a doll for her next birthday present she would ask her mother to have the summer-house pulled down."

Child Photography in the Studio.

An afternoon at the children's photographic studio is both amusing and instructive. The writer of the article, anxious to obtain some insight into the art of photographing children, obtained permission to conceal himself in a room adjoining the studio, where he could watch operations unobserved. Soon a little girl of seven, accompanied by her mother, came in. "What have 'oo got to 'muse me to-day?" said the child; "last time I came we played bears." The photographer admitted that it was so, and suggested a repetition of that ingenious game. "Oh, no," replied the young lady, imperiously, "I'm too old for bears now"—dictatorially, "find something else." Accordingly, cuckoo clocks, shaggy monkeys on sticks, and talking dolls whose linguistic feats were confined to "mamma" and "papa," were brought forth, one by one, but all to

no purpose. "I've seen those before," said the child in tones which plainly showed that as far as she was concerned the matter was closed.

A "Live" Accessory.

At this moment a Great Dane dog walked in dignified and stately manner into the studio, and, lazily wagging its tail, ambled up to the child and held down its head to be patted. From that moment all was well, for, oblivious of the patiently waiting photographer and anxious mother, the child made firm friends with the new pet, and was accordingly taken without any further trouble and without the need for stiff and unnatural poses. Apparently there are degrees and degrees of amusing children in these days, and, as the blasé critic scorns the old-fashioned pantomime, so does the twentieth-century child, experienced in the old-fashioned wiles of the photographer, treat with contempt such hackneyed decoys as cuckoo clocks and monkeys on sticks.

The Modern Child.

Years ago a visit to the photographer was an important event

in a child's life; to-day, however, the fashionable young lady of a whole ten years' experience of the trials and troubles of this world looks upon the proceeding as quite a commonplace event. "I shall be photographed as a bridesmaid to Lady —," mentioning a well-known lady's name, "next week," remarked one blasé child of ten as she left the studio where she had just been taken in the costume of a flower-seller at a recent large charity bazaar, "and at the end of the month I am to be taken in my skirt-dancing dress." It afterwards transpired that this world-weary child had already been taken five times since the beginning of the season. The patience which mothers show when their children are taken would prove a veritable eye-opener to those cynics who declare that the modern mother thinks more of the all-important matter—dresses—than she does of her children. The writer during his afternoon's reconnoitring saw one lady, dressed in the height of fashion, submit to having a tennisa toque all but mutilated beyond repair because her little girl took a fancy "to those pretty flowers in mother's hat."

INFLUENCE OF THE LENGTH OF THE TIME OF DEVELOPMENT ON THE DEGREE OF DARKENING OF THE PHOTOGRAPHIC PLATE.

(A Paper read before the Society of Chemical Industry.)

Although the density of a photographic plate depends upon the time of exposure, the developer, nature of bromide of silver* and of colloid in which it is emulsified, etc., yet it is also influenced in a great degree by the time of development.

When the same kind of plates and developers are used, the density for one and the same exposure varies according to the time of development on keeping the temperature constant.

An investigation of this subject was made in the following manner:—

As the developers, edinol and ferrous oxalate of the following compositions were used. The former is known as a rapid, and the latter as a slow, developer:—

1. EDINOL DEVELOPER.

A.	Edinol (powder)	1 gm.
	Sodium sulphite	8 gm.
	Water, make up to	100 c.c.
B.	Potassium carbonate	50 gm.
	Water, make up to	100 c.c.
For use 80 parts of A and 20 parts of B are mixed.		

2. FERROUS OXALATE DEVELOPER.

A.—Saturated solution of ferrous sulphate containing 2 per cent. citric acid.

B.—Saturated solution of neutral oxalate of potassium.

For use 20 parts of A and 60 parts of B are mixed.

The exposure was carried on in the following way:—

Four narrow pieces of an ordinary dry plate (the extra rapid dry plate of Lomberg was used) were loaded in a dark slide. Each 1 cm. of the four pieces was exposed at the same time to a Hefner's standard amyl acetate lamp at a suitable distance, the exposure varying from one (Hefner metre seconds) to 153,600 (Hefner metre seconds). Two of the four pieces were developed with the ferrous oxalate developer and the other two with the edinol.

The time of development with both developers were selected as follows:—

Series I.	10 seconds.
Series II.	20 "
Series III.	40 "
Series IV.	80 "
Series V.	160 "
Series VI.	320 "

The exposed plates were developed always with a constant amount of developer at 18 deg. C. After the development, the plates were laid in 20 per cent. thiosulphate solution for ten minutes and then were washed under running water for one hour.

The density was determined by the Martens's polarisation photometer, and calculated according to the formula given by Martens and Michéll†

$$Dr = 2(\log \tan \alpha - \log \tan S).$$

Dr means the relative density of the developed plate; α , the angle of rotation of Nicols for the part of the plate the relative density of which is to be measured, when both semi-circles of the field of the photometer appear equally light; S, the angle of rotation of Nicols for the unexposed but developed part of the same plate.

Tables I. and II. show these results graphically. [Not reproduced.—Eds., B.J.P.] The curves are constructed in such a way that the ordinates represent the relative density, and the abscissæ, the logarithms of ($i \times t$), i.e., the logarithms of the product of the intensity of light in H.M. and the length of the time of exposure in seconds.

The result show that—

(i.) The density of a photographic plate for an exposure of the same length of time and when developed with the same kind of developer increases according to the increase of the time of development.

(ii.) When the time of development is short, there is no great difference in the density by changing the effectual exposure $i \times t$.

(iii.) By increasing the time of development the differential quotient $\frac{d Dr}{d \log i \times t}$ becomes greater.

(iv.) At an exposure for the same length of time the ferrous oxalate developer gives less density than edinol when the plate is developed for a short time; but when the plate is developed for a long time the former causes a greater density than the latter.

On comparing the relative densities at the corresponding exposures for the successive lengths of time of development the results shown on next page were obtained.

Total mean=1.630						
Mean deviation=+ 0.085						

$DT_1, DT_2, DT_3, DT_4, DT_5, DT_6$ mean the densities at the corresponding exposures for the lengths of time of development 10, 20, 40, 80, 160, 320 seconds respectively.

From these data the following Exponential Law of Development may be deduced:—

EXPONENTIAL LAW OF DEVELOPMENT.

(i.) Within the range of the normal exposures, neutral zone inclusive, the density ratio for any two lengths of time of development is constant and independent of exposure ($i \propto t$).

(ii.) The density at a constant exposure is proportional to a certain power of the length of time of development.

(iii.) The density at any exposure for the length of time of development 2^2T seconds is equal to that of T seconds at the corresponding exposure multiplied by C , where C is a constant.

In conclusion I desire to express my thanks to Professor J. Precht, of the Technical High School of Hanover, for his assistance in this investigation.

CHIRI OTSUKI, PH.D.

AN AMERICAN NOTE ON CHILD PORTRAITURE.

HE characteristic type of work that distinguishes the best American portraitists has often formed the subject for comment in the Press. Whether this difference in style is due to the individual or to environment it is difficult to say. The American professional has undoubtedly done much to heighten the general standard of photography of children, not only in the States but also in this country. The following notes from an American source may therefore prove of interest to those who have observed this influence, and sought to discover the cause.

One of the best-known women photographers in New York speaks of the difficulties of child photography, and in an interview with the New York Telegram," says:—

"Posing a child for its portrait is a matter of time and hard work. Some few methods of overcoming the difficulties of the situation are described and endeavours are made, as far as possible, to analyse the means of success. 'I hardly know how I get children to sit so admirably for me,' said she. I suppose, however, that it comes from an entire understanding of children. Probably the mode of treatment differs with each child. They must be managed according to temperament. Yet I never set out to win their goodwill. On the other hand, I rather neglect them, simply leaving them alone to become acquainted with the studio. One or two general rules I do follow, though I never antagonise a child. Rather I humour it, when it is begun to be interested in me. Again, if I begin to think that a certain pose would be just the one for a child to take, it almost invariably happens that this is the last that is natural to him. I never pays to have a preconceived idea of a child's pose. I simply let the boy or girl wander about until I see what it is that he wants to do, and what he will do. Sometimes when a child does not want to do what I desire him I say, 'You won't do that, will you?' Nearly always the mischief in the child makes it go at once

and do that very thing. After one has often failed to make a good picture of a child in its best gown one can achieve a great success by merely slipping an old frock on it. I never let a child become excited. Some persons think tots must be on the *qui vive* in order to look bright, but this is not true. One can never work as well from an excited child.

"I don't consider it difficult," continued the photographer, "and there is no one I would rather see coming into my studio to be photographed than a little child. Perhaps if I had not always loved to be with children I might speak differently, for it takes time to get a child's portrait. I refuse to attempt to do so in less than an hour, and often it takes two or more. However, it depends very largely on the child. The moment he tires and shows the least signs of peevishness it is time to give up all effort for the day and try again some other time, when he is fresh. The mother may bribe it to remain quiet with a promise of chocolates, but the picture will be a failure. I don't mean to say that there is no work about photographing a child in a natural way, but I do believe if a woman has the knack of making these child portraits she will find the labour so fascinating that she will not call it drudgery. I suppose one has to have the gift of managing children born in them. The end to be obtained is to get them posed as unconsciously as possible. I like best to photograph one child alone. I want also as few accessories as possible in the picture, for it is my object to make a portrait of the child; that means to reproduce it as it is—to translate its temperament into the photograph. I don't mind a doll in the picture, and always keep a few toys at hand for the children, but I never pose a child at a tea-table. There would be too much distracting detail in such a photograph. This is merely my personal taste in the matter, however. Laughing portraits I seldom take. They are easy to get, but the result is usually a foolish grin. A child should look bright and intelligent, and a smiling child rarely does so. A child's interesting moments are its grave ones."

GLASGOW Eastern Exhibition.—The annual exhibition of the Glasgow Eastern Amateur Photographic Association will be held from November 25 to December 2 next. In addition to five classes for members, there will be two for associates of the Scottish Photo-

graphic Federation—one for prints and one for slides. To encourage the joint outings with the Shettleston Camera Club a special class for the members of that club and the Eastern has been included for work done at the joint outings.

THE MAWDSLEY FUND.

THE INTERNATIONAL CONGRESS OF PHOTOGRAPHY.

THE meeting of the Congress to be held at Liège from July 19 to 24 has already been announced in our pages, and we are now able to give a list of papers to be communicated, which at the time of writing stands as follows:—

Report of the Permanent Commission on plate speeds, standards, etc. M. E. Wallon, Paris.

The substitution of volumes for weights in photographic formulae. Dr. Henrstay, Angiers.

New researches on detection of forgeries, and other questions of photography applied to criminology. Dr. Reiss, Lausanne.

Fixation of pigmentary inks for three-colour photography and adjustment of light filters thereto. Prof. R. Namias, Milan.

On the composition of mixtures of gelatine and metallic bichromates after exposure to light. A. and L. Lumière, Lyons.

On the theory of stereoscopy. A. Goderus, Gard.

The photographic reproduction of manuscripts. J. Casier, Gard.

The Permanent Commission of the Congress by whom the report above referred to will be drawn up consists of the following:—
Bellieni, France; Miethe, Germany; Cameron, United States; Moissard, France; Chapman-Jones, England; Pizzigelli, Italy; Clerc, France; Puttemans, Belgium; Demole, Switzerland; De Sambuy, Italy; Drouet, France; Gl. Sebert, France; Eder, Austria; Trezniewsky, Russia; Gaumont, France; Walton, France; Houdaille, France; Louis Lumière, France.

As we have already announced, British visitors are invited to the Congress and communications from those desirous of attending should be addressed to M. Ch. Puttemans, Palais du Midi, Brussels.

FORTHCOMING EXHIBITIONS.

July 4 to August 12.—Northern Photographic Exhibition. Secretary, F. G. Issot, 62, Compton Road, Harehills, Leeds.

July 15-25.—Sixth International Salon Association Belge de Photographie, Liège. Secretary, Mr. Servais, 34, Rue du Saint-Esprit, Liège.

August 7.—Andover. Hon. Secretary, W. I. Gradidge, Jubilee House, Andover.

September.—Royal Photographic Society, New Gallery, Regent Street, London, W. Secretary, J. McIntosh, 66, Russell Square, London, W.C.

September 15-October 21.—Photographic Salon, 5a, Pall Mall East. Hon. Secretary, Reginald Craigie, Camera Club, Charing Cross Road, W.C.

October 28-November 4.—Sheffield Photographic Society. Joint Hon. Secretaries, J. W. Charlesworth, 1 Joshua Road, Sheffield, and James W. Wright, 62, Vale Road, Sheffield.

November 14, 15, 16.—Ipswich Camera Club. Hon. Sec., R. H. Sutton, 37, Henley Road, Ipswich.

November 21-25.—Southampton Camera Club. Hon. Secretary, S. G. Kimber, Oakdene, Highfield, Southampton.

November 25-December 2.—Glasgow Eastern Amateur Photographic Association.

December 1-6.—Hove Camera Club. Hon. Secretary, A. R. Sargeant, 55, The Drive, Hove.

December 12-20.—Southsea Photographic Society. Hon. Secretary, F. J. Lawton, 5, Pembroke Road, Portsmouth.

March 3-10, 1906.—South London Photographic Society. Hon. Sec., H. Creighton Beckett, 44, Edith Road, Peckham, S.E.

March 6-20, 1906.—Glasgow Southern Photographic Association. Hon. secretary, William H. Frame, 28, Bank Street, Hillhead, Glasgow.

FORTHCOMING COMPETITIONS.

July 15.—Warwick. Money prizes for members of photographic societies for pictures taken on Warwick Dry Plates. Warwick Dry Plate Company, Warwick.

September.—Kodak. £400 in prizes for results on Kodak products. Kodak Ltd., 57-61, Clerkenwell Road, London, E.C.

October 1.—Thornton-Pickard. £100 in prizes for photographs taken with Thornton-Pickard cameras or shutters.

Photo-Mechanical Notes.

A New Method of Using Prisms and Mirrors.

M. CALMELS points out in "Le Procédé" that the usual method of mounting a prism on the front of the lens is extremely liable to produce, in consequence of the weight on the lens mount, unequal strains in the glass, and consequent loss of sharpness through double refraction. Further, that the aperture of the prism is usually circular, corresponding in diameter to the aperture of emergence, which results in a cutting off of the field. To obviate these difficulties, he has calculated out the exact size which it is necessary to give to a prism which can be mounted behind the lens, and the base of

the prism is surrounded by a metal rectangle 4 mm. wide, which can be fastened to the camera front, either direct or on an extension cone which fits the camera front and entirely obviates any curtailment of the angle. The figure shows Calmels' new idea, the lens being screwed into the ring, which can be rotated so as to enable the orientation of special diaphragms for trichromatic work. Precisely the same idea can be applied to the mirror, and the size and weight of both prism and mirrors and the necessary mountings thus considerably reduced.

Wet Collodion Troubles.

The most persistent difficulty in wet plate negative-making is the presence of dust. A perfect sea of troubles arises from

his one small cause alone. One dares not leave windows near the dark room open without screening with several thicknesses of muslin in order to filter the air, and we recently heard of an unfortunate operator who was puzzled by very peculiar spots, which he afterwards traced to the fact that a fire had taken place in a large timber yard in the neighbourhood, and the very fine particles of burnt wood had found their way down the ventilator, and so on to his plates. Again muslin was the remedy. Dust can most effectively be laid for the time being by vigorously using a barber's scent spray filled with water, just before coating is done, but this should not be necessary except on very rare occasions. The dark room for wet plate work should be free from everything except necessities, the walls and ceiling should be painted and the floor concrete, or at least oilcloth, so that the whole room can occasionally be washed throughout.

A peculiar trouble once afflicted a large firm on the Continent some years before they discovered the cause. Their plates could be working well, when suddenly they would begin to fog, get spotty, and, in short, become entirely useless. The operators might be a day or two in misery before things just as suddenly righted themselves again. After making no end of experiments, including the tearing up of the drains, without avail, it was at last found to be due to the dry east wind! Now, when the same symptoms begin to appear, the doors are well watered, and wet cloths laid on the steam pipes, with the result that the trouble is entirely avoided.

A Good Photo-Transfer Ink.

Although good stone-to-stone transfer inks can be purchased, still those who make their own, despite the trouble, are always satisfied they have a better article than they can buy. Here is a well-tried formula for such an ink. It can be recommended also for making the albumen prints for line etching:—

- | | | | | | |
|------------------------------------|-----|-----|-----|-----|-------------------|
| 1. Black pitch | ... | ... | ... | ... | $\frac{1}{4}$ oz. |
| 2. Orange shellac | ... | ... | ... | ... | 1 oz. |
| 3. Mutton suet | ... | ... | ... | ... | 2 oz. |
| 4. Castile soap | ... | ... | ... | ... | 1 oz. |
| 5. Black chalk litho ink (6s. lb.) | ... | ... | ... | ... | 12 oz. |

The ingredients should be put into a decent sized iron saucepan on a stove in the order named, each ingredient being allowed to mix thoroughly well before the next is added. The mutton suet requires scalding, to get the skin away, before it is added, and the fat may be melted from it and then run into the saucepan, leaving the skin behind. After thoroughly mixing, so that a perfectly homogeneous mass results, the saucepan is taken out of doors, a match put to the contents, and the ink allowed to flame away for twenty minutes, when the lid is put on the saucepan. The ink now looks rather peculiar, the top being very lumpy and charred, but it only requires to be passed through an ink mill, which any ink-maker will do for a trifling charge, when it is quite ready for use. For photographic work, the ink is thinned with turpentine, and with a drop or two of oil of spike lavender. For lithographic work it may be thinned with thin litho varnish.

MRS. CATHARINE WEED WARD writes us:—So many of your readers have written to me, in consequence of your kind note re my accident that I beg you to allow me to express here my very sincere appreciation of their sympathy. The accident, which took place on May 23, came very near being fatal, but I was able to be brought home on Saturday, June 17, with only slight permanent injuries, and only requiring rest for a complete recovery. Within a week or two I hope to fully resume my editorial and journalistic work; and, if all goes well, I must to thank many of your readers personally at the Photographic Convention next month.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

The following applications for patents were made between June 5 and 10:—

ISO SCREENS.—No. 11,765. Improvements connected with screens for use in isochromatic photography. Harry Ernest Staddon, 173, Fleet Street, London, E.C.

PLATEHOLDERS.—No. 11,786. Improvements in photographic plateholders. Jesse Daugherty Lyon, 18, Southampton Buildings, Chancery Lane, London.

CAMERAS.—No. 11,882. Improvements in photographic cameras. Alfred Edward Bloxsome Ray, 37, Chancery Lane, London.

DISHES.—No. 11,985. Combined development and washing trays for photographic purposes. John Marshall, 37, West Nile Street, Glasgow.

FILING PHOTOGRAPHS, ETC.—No. 12,029. A new and improved device for storing photographic films, unmounted photographs, newspaper cuttings, etc. Percy Gerald Reynell Wright and Houghtons, Limited, 88, High Holborn, London.

CAMERAS.—No. 12,030. Improvements in photographic cameras. Herbert Holmes and Houghtons, Limited, 88, High Holborn, London.

DRY MOUNTING.—No. 12,057. Dry mounting photographic paper (both "printing-out" and "developing"). John Merrett, Trowbridge, Wilts.

COMPLETE SPECIFICATIONS ACCEPTED.

Specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

MEASURING SHUTTER SPEEDS.—No. 16,053, 1904. The claim is for apparatus for the testing by a visual method of the speed of photographic shutters. The instrument consists of a stationary plate formed with a slit arranged in front of a source of light, in combination with a revolving disc formed with a slit or slits arranged to travel over the slit of the stationary plate, so that this latter stationary slit appears to be illuminated owing to the principle of persistence of vision. On this action being viewed through the aperture of a shutter which has a shorter period than that of the slit, a dark portion is seen in the slit corresponding in length relatively to that of the slit equal to the difference of periods, which, by gradually increasing the speed of the disc until the dark line is just eliminated, indicates that the period of the shutter and the slit are the same. In timing shutters of the roller-blind or focal-plane types, by employing the speed measuring apparatus with the shutter aperture working parallel to the stationary slit, good results are readily and easily obtained. Abraham Kershaw, Torrington Street, Leeds.

ENLARGING CAMERA.—No. 1,364, 1905.—A camera for both studio and enlarging work. The apparatus comprises a lantern box, lantern, lens, carriers, negative carrier, easel, etc. By bringing together these parts in a suitable manner the apparatus is used for one or other of its two purposes. John Norman Anderson, 178, Wabash Avenue, Chicago, U.S.A.

TRIPOD HEADS.—No. 16,359, 1904. Protection is claimed for a ball-jointed tripod head, the ball joint of which is carried in a

casing, such as 14 and fitting 9, and has a pillar 12 with pinching pin 34, a revoluble stem 28 in the pillar with suitable means to

Figs. 1 and 2.—Sectional side view and side view in elevation of ball-jointed head.

prevent its removal, such as garter pin 30. It has a plate 31, a revoluble table 13 on same, and means on the stem 28 for attachment to the camera, and for adjustably securing ball 11 in its casing. John Ambrose Sprason, St. George's Place, St. George's, Birmingham.

New Books.

"Benson's Facts for Advertisers. 1905." (London: S. H. Benson. 5s.)

Here we have a book, now in its first edition, dealing with the data of the advertising business in a concise and direct manner. It is a collection of useful information which is being continually required by the ad-man, and which usually has to be looked out from various sources. The arrangement of the book is good—the facts are classified in five sections, under the general headings of General Information, Technical Information, Newspapers and Magazines, Out-door Publicity, and Colonial and Foreign Advertising. Each section is printed on a differently tinted paper, thus reducing to a minimum that annoyance generally attributable to handbooks, etc., in finding what is wanted at a moment's notice. Ten minutes' time is sufficient to familiarise one's self with the scheme of the book, after which reference to the index even should hardly be necessary. The volume is certainly of value to photographers who appreciate the power of advertising a studio, as it has much to say on the various media of advertisement, press, circulars, railway, etc., and it appeals also to all photographers, who may think of applying their cameras to modern illustrated advertisement, by reason of its notes and information of current reproduction processes considered commercially.

"THE PLEASANT ART OF PHOTOGRAPHY MADE EASY," adds still another to the many elementary text-books on photography. The author, however, takes hope from the very profusion of literature of the order to which his work belongs, that there is room for one more, and we will do him the justice to say that he discourses on his theme in a pleasant, easy-going way, and manages to convey technical instruction without being dull; and usually his advice is sound technique. The publisher of the book is Guilbert Pitman, 85, Fleet Street, London, E.C., who issues it at 1s. and 1s. 6d.

"HOW TO USE THE CAMERA," by Clive Holland, is the title of an elementary handbook for photographic beginners published by Geo. Routledge and Sons, Limited, at 1s. It is copiously illustrated with reproductions intended to illustrate the various points dealt with by the author in the text.

A SERIES of practical articles by J. Cruwys Richards on gum-bichromate work, which originally appeared in "Photography," has been published in book form by Messrs. Riffe and Sons, Limited,

under the title of "The Gum Bichromate Process." Mr. Richards deals in a complete manner with the process, and the ten chapters composing the book are illustrated with examples of his work.

New Apparatus, &c.

The No. 1 Folding Pocket Kodak (New Model). Made by Kodak Ltd., 57-61, Clerkenwell Road, London, E.C.

In the 1905 pattern of the well-known No. 1 F.P.K., the Kodak Co. have modified the design in certain important particulars, the nett result of which is assuredly to enhance the value of the instrument in the eyes of the photographic tourist. The working parts are now enclosed by a folding baseboard, so that all mechanism is protected from dust and wet. This safeguard does not entail another

No. 1 F.P.K. (New Model), showing how the lens front moves forward on opening the camera.

operation, for, by a most ingenious device, the lens front is drawn into its proper position by the simple act of drawing down the base-board. In an instant you pull down your cover-board and your lens steps forward into position with almost the human intelligence of a West-end shopwalker. There are other improvements, but this one of the automatic moving front is the only one which the dealer need demonstrate when exhibiting the camera to a customer. It exerts a subtle "there-you-are-Madam" kind of influence, which, if we are not mistaken, will be irresistible. The price remains the same—£2 2s.

The "Swingcam" Camera Stand. Invented and sold by William Butler, 20, Crosby Road, Birkdale, Southport.

Every conceivable position for the camera wherever it may be necessary to plant the tripod—that is what the inventor of the "Swingcam" stand offers to achieve. The construction on which the stand relies to carry this promise into execution is a comparatively simple one. Each leg of the tripod is connected to the head by an attachment which is doubly jointed and also is free to turn at its point of junction with the head. As a result, the tripod acquires a mobility of its parts which permits of the most extreme positions being taken by the camera. The stand being fixed in its normal position, it is the work of a second or two to adjust matters so that the camera points vertically downwards: or just as expeditiously it can be pointed upwards. Any inclinations between these limits are obtainable and the jointed attachment of each leg enables the tilt to be altered without disturbing the position of the feet. In short, the tripod has a greater range of movement than a ball-and-socket head, without the weakness which, by its construction, the ball head

cesses. In the most exceptional positions it is highly stable and rigid, a fact which we attribute to the mechanical strength, yet simplicity, of the jointed attachments. A photographer need not be occupied with the very special work of natural history, surveying, or similar photography—for which the maker specially offers the tripod—in order to prove the value of its great range of movement. To take various positions, in which it is often advisable to place a camera—right

The "Swingcam" Stand, showing triple attachments and extension pieces.

the corner of a room or flat against a wall. With an ordinary tripod it is impossible to do so without sacrificing rigidity, but with the "Swingcam" these particular movements are made at once, and the camera is placed with all necessary stability. Moreover, when thus secured, it can be tilted up and down through a large angle. We venture to say that anybody who has to do photography in confined quarters will appreciate this feature of the tripod. There are some other technical points we might refer to, such as the attachment which keeps the points of the legs vertical however much the legs are spread out, but a booklet issued by the inventor sets forth these and other details by aid of a number of illustrations. The normal height of the tripod is 4 ft. 9 in.; with extension bars, 7 ft. 3 in.

The Cairo correspondent of the "Pelican" writes that "the fashionable mania in that city is to be photographed in mummy frames. These are really coffins, and the spectacle of a pretty woman, in any costume, reclining in one of these gruesome relics of a past age, can only be described as weird in the extreme."

Messrs. P. LEUTHARDT-THORNTON and G. B. Leuthardt-Thornton inform us that they have opened offices at Terminus Chambers, 6, Colborn Viaduct, London, E.C., and have commenced business as general merchants under the name of L. Thornton and Son.

News and Notes.

M. GABRIEL LIPPMANN is reported as stating, in a paper before the Paris Academy of Sciences, on June 3, that in the case of photographs on bichromated gelatine films it has been hitherto necessary to moisten the film each time it is desired to observe the colours. By alternate treatment with solutions of potassium iodide and silver nitrate the colours become permanent and visible after drying.

MANY photographers occasionally want a reliable firm to quickly produce a good half-tone block from their prints, either for advertisement purposes or for picture postcards. The work done by The London Studio, of 20 and 22, St. Bride Street, Ludgate Circus, is well known, and the rapidity with which they turn out orders will appeal to every one who gives them a trial. The quality of the work we have had an opportunity of examining is very high.

SOUTH LONDON Excursion to the Antrim Coast, 1905.—Thursday, July 20, leave Euston about 4.15 p.m., or St. Pancras about 8.20 p.m. Friday, July 21, arrive Larne about 8 a.m. (King's Arms Hotel), breakfast on arrival, remaining to Saturday morning. Saturday, July 22, leave Larne for Garron Tower, passing through Glenarm and Carnlough; dinner, tea, and bed at Garron Tower. Sunday, July 23, at Garron Tower, visiting Glenariffe Waterfalls. Monday, July 24, after breakfast leave for Ballycastle (Hunter's Hotel), passing through Cushendall and Cushendun; walking to Fair Head. Tuesday, July 25, leave for Giant's Causeway (Kane's Royal Hotel), calling at Carrick-a-Rede. Wednesday, July 26, day at the Causeway, with drive to Portrush. Thursday, July 27, drive across country to Garron Tower, remaining overnight. Friday, July 28, drive to Larne, leaving about 5 p.m., arriving London Saturday morning, 29th. The cost of this trip would be as follows:—Hotel expenses, 23; drives, £1 5s.; return fare, £1 8s. 6d. Cost of taking cycles is about 12s.

INTRUSIVE Photographers.—A correspondent of the "Yorkshire Daily Post" at Oberammergau, referring to the influx of visitors there, many of whom have secured room for themselves and friends who are desirous of seeing the performance of "The School of the Cross," hopes that no English visitors will copy certain Americans who have already found their way there. In spite of the strictest prohibition by the Oberammergau authorities, and remonstrances couched in most courteous language, some of these people insisted on bringing cameras into the theatre on Sunday, June 4, and in taking snapshots of the performers and some of the audience. This would in any case be in extremely bad taste, but in view of the prohibition known to everybody it is a violation of rule which might fitly be punished by strong measures. One American was spoken to no fewer than three times, but this did not prevent her from continuing her snapshotting, though she contrived to change her seat so as to be out of the reach of further remonstrance. Why cannot these people try to live up to their blue china?—pertinently asks the correspondent.

MESSRS. RUSSELL AND SONS were honoured with Royal commands at Windsor Castle last week, and took a number of photograph groups of the Royal bride and bridegroom, the Crown Prince and Princess of Sweden, Prince Eugene, and of the Prince of Wales and the members of the Royal Family.

THE Camera as a Temperance Reformer.—The secretary of the National Temperance League, writing in the "Express," says that: "Flats and the camera are among the contributory causes of the new habit of sobriety that is coming over the people. A person living in a flat has no room for a wine cellar, while families living in mansions often find that the wine cellar makes an excellent dark-

room, evicting the bottles of old port to make room for the new pyro." Apart from this, however, we are of the opinion that the widespread popularity of amateur photography takes many men, who would otherwise spend a considerable amount of time and money at lars, out into the open air in pursuit of their hobby, and thus effect a saving in health and pocket.

"FOUR narrow pieces of a dry plate were loaded in a slide casset." This from a paper in the "Journal of the Society of Chemical Industry." It may be pardoned, as from the MS. of a Japanese, resident in Germany and writing in English.

DARK ROOM Safe Lights.—A communication from Professor Adolf Miethe on this subject, which we have been enabled to peruse by courtesy of Messrs. A. E. Staley, sums up the requirements of dark room filters for various purposes, some extracts from which we quote. Mr. Miethe's notes are in reference to the gelatoid filters, of which Messrs. Staley are British agents. Ordinary dry plates, and more so, the ordinary bromide papers, are highly non-sensitive to yellow and red, so that a dark room illumination which transmits orange, red, and even a portion of the yellow light, may be employed. These requirements are met by a filter transmitting light from the extreme red to a wave length of 590. With proper precaution this filter admits of safely developing even most sensitive ordinary plates. A filter which transmits light to a wave length of 620 is, notwithstanding its brightness, applicable—when properly employed—not only in the case of most sensitive ordinary plates, but also for ordinary colour-sensitive plates (erythrosine plates), and is the most suitable one for ordinary use in the laboratory. It answers all requirements that can be made of a very bright, and withal, very safe, dark room light. The filter gives a light six to seven times as bright as that obtained through the best ruby glass of equally slight photographic action. For developing highly colour-sensitive plates, more especially those sensitive to red, the dark red filter No. 4 is suitable: it transmits light only to a wave length of 670, corresponding in brightness to good, medium, bright ruby glass. For individuals upon whom red light doubtless exerts an unfavourable influence, green and brown light-filters supply a sufficiently safe and very agreeable light for working with ordinary dry plates. The light transmitted by this filter consists of two bands of spectrally different light, of one deep red and one yellow-green, which, by combined action on the eye, produce the impression of green.

THE latest wholesale price-list of fine chemicals reaches us from Messrs. Harrington Bros., 4, Oliver's Yard, City Road, London, E.C.

INSECT PESTS.—The "Bromide Monthly" draws attention to the fact that the common earwig will create considerable havoc with damp gelatine films of all kinds, particularly at night when they come out on the prowl for food. Judging from some reproductions we have seen of their ravages one earwig can completely ruin a negative, and the glass is practically cleared of silver and gelatine. It has been known, of course, for some years, at least ten, that flies had a decided fancy for damp gelatine, and that they very frequently cause clear round spots almost like pinholes by clearing off the gelatine and image. By long continued washing in summer, which, by the by, is quite unnecessary, the gelatine is so softened that it may well become partially soluble, and there is a particular microbe which has a name as long as its body is short which delights in well-washed gelatine. This particular pest causes groups of clear spots, which when examined with a glass are seen to be totally devoid of gelatine. The obvious remedies are short but efficient washing and quick drying, and the latter can always be hastened by the use of successive baths of methylated spirit.

WE regret to record the death of Mr. T. C. Hepworth, which took place on the 14th inst., and to whom we will refer further next week.

Commercial & Legal Intelligence

SERVANT Victimised.—James Watson was charged, on remand at North London, with stealing a half-sovereign belonging to Martha Turnbull, a domestic servant, of Canonbury. The prisoner went to the house where the prosecutrix is employed, and solicited an order for photographs. She consented to pay him 4s. on account, but had no change. She handed the prisoner a half-sovereign to get changed, and he did not return. According to the police, the prisoner had not been previously convicted, though there were several complaints that other servants had been victimised in similar fashion, but they would not come to identify the prisoner. Mr. Fordham said that it was a mean theft, and one that he was afraid was rather prevalent. The prisoner had been in gaol a week, and would now go for a further twenty-one days.

CERIOTYPE COMPANY, LIMITED.—This company has been registered, with a capital of £1,000 in £1 shares (nine founders). Object, to adopt an agreement between J. Wagner and E. L. White to manufacture, in accordance with a secret process, materials for sensitising paper, and other materials for photographic purposes, and to carry on the business of photographers, photographic printers, etc. No initial public issue. The first directors are E. L. White, C. Fitch, and T. K. Grant. Registered by A. W. Bartlett, 6, New Square, Lincoln's Inn, W.C.

PHOTOPHANE PRINTING COMPANY, LIMITED.—This company has been registered, with a capital of £5,000 in £1 shares. Object, to take over the business of photographic printers and otherwise carried on by the Photophane Company at the Cranfield Works, Brockley, Kent. No initial public issue. The first directors are H. A. Hutchinson and H. Whitworth. Registered office, 36, Corn Street, Bristol.

A PHOTOGRAPHIC POLICE TRAP.

MOTORISTS BEWARE.

WE read in a Wolverhampton paper an account of an interesting invention which will shortly be placed on the market by a firm in that city. It affects the police and users of motor-cars, and is to be known as the "time-recording camera." Judging from the description the results will probably cause more disputes and wranglings in Court than any previous method employed by the police. A representative of the paper had the invention explained to him. He says:—"The instrument is simplicity itself, the photograph of a passing car being taken by the simple act of pressing a button, as in the case of a snap-shot camera.

"It is really a photograph of the car, the road, and the time which results from the act of pressing the button. The instrument is, in fact, a camera which takes a watch, a signed dating card, and a numbering machine. The watch case can be officially sealed up, and the operator cannot tamper with it. If required, the photograph thus taken may be finished as evidence, while the instrument should be greatly used in time trials and so forth. Any rapidly-moving object may be taken at any given point, and the shutter speeds give a range of exposures from one-twenty-fifth of a second to one-hundredth part of a second. The exact time is shown, the date appears, and the film number. A car may be timed over any distance, and not only is the vexed question of speed to be settled, but the occupants at the moment are photographed, and can readily be identified."

WE look forward with considerable wonder to seeing the kind of photographs that will be produced by this wonderful instrument.

WE regard the possibilities of recognition attached to a photograph of a car travelling at over twenty miles an hour, taken broadside on by a shutter giving exposures from one-twenty-fifth of a second to one-hundredth, as extremely remote.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

June.	Name of Society.	Subject.
14.....	Manchester Amat. Photo. Soc.	Trip to Hathersage.
14.....	North Middlesex Photo. Soc.....	Outing to King's Langley, for Chipperfield.
14.....	Cricklewood Photo. Society.....	Outing to The Hale.
14.....	Hull Photographic Society.....	Outing to Burton Bushes.
14.....	Wallasey Amat. Photo. Soc.....	Field Day.
14.....	Watford Camera Club.....	Langley Lodge Farm.
15.....	South London Photo. Society.....	Trip to City of London.
16.....	Wallasey Amat. Photo. Soc.....	"Use of the Camera." Mr. R. Tunnicliffe.
26 and 28	Everton Camera Club.....	Evening Outings vs Class 1 Competition.
17.....	Royal Photographic Society.....	Technical Meeting. "The Romantic in Landscape." Mr. F. C. Tilney.
27.....	Manchester Amat. Photo. Soc.	"Auto Pictorial." Mr. J. E. Latham.
27.....	Southport Photographic Society	Mold, Loggerheads, and Leete, in conjunction with the Liverpool Photographic Society.
29.....	London and Prov. Photo. Assn.	Annual General Meeting.

CHELSEA AND DISTRICT PHOTOGRAPHIC SOCIETY.—Mr. E. A. Salt gave an interesting demonstration on the platinotype process before the members of this society at the South-Western Polytechnic on the evening of June 1.

THANET PHOTOGRAPHIC SOCIETY.—The annual meeting of this society was held at the club-room, Broad Street, Ramsgate, on Thursday evening of last week. The report showed that the year commenced with 77 members, 20 new members were elected, 11 resigned, and 86 remained. Ramsgate headed the list with 59 members, Margate had 22, Broadstairs 4, and Sturry 1. The exhibition was held at the Pavilion, Ramsgate, in November, and a very good entry was secured in the open classes. Arrangements are being made for the next exhibition to be held at the Public Library, about November 23. The following officers were appointed:—President, the Rev. L. J. White-Thomson; vice-presidents, Dr. B. Richards, the Rev. C. E. Eastgate, and Messrs. G. F. Blower, J. H. Forwalk, P. Solly, L. G. Hodgson, and G. W. Simmers. Mr. S. H. Page was elected hon. secretary; Messrs. Hacker and Solly were elected auditors; Mr. P. F. Weeks, hon. lanternist; Mr. L. G. Hodgson, hon. librarian; Dr. Richards and Mr. S. H. Page, delegates to the R.P.S.; and Messrs. Vigar, Francis, Savage, E. Deacon, Hoile (Ramsgate), and Gibbs, Redman, and Adutt (Margate), committee. Mr. Hodgson promised to act as secretary to the November exhibition.

ROTHERHAM PHOTOGRAPHIC SOCIETY.—A meeting of the Rotherham Photographic Society was held on Tuesday evening of last week, when special attention was devoted to the difficulties of beginners, the three vice-presidents giving the benefit of their knowledge. Mr. J. W. Stamp spoke on apparatus and exposure, Mr. W. Firth on developing plates and varying exposures, and Mr. J. Leadbeater on the toning of a batch of P.O.P. prints.

A PROPOSED COMBINED OUTING.—At the last meeting of the South Essex Camera Club, the president (Mr. Walter D. Welford, F.R.P.S.) laid before the members the idea of the various East London and South Essex photographic societies combining on, some date in September for a joint excursion—partly for photographic work, but chiefly as a social gathering. He thought that it would prove a very pleasant event, and might be productive of good in several directions. The idea was very favourably received, by the members, and the hon. secretary was empowered to send out invitations to the various societies. Any societies in the district named not receiving an invitation are requested to communicate with the hon. secretary, J. Michell, 180, Browning Road, Manor Park, E.

"SITUATIONS WANTED."

To the Editors.

Gentlemen,—In one of your recent issues a letter or suggestion appeared that if an employer advertised for an assistant it would be only fair and reasonable that each should pay his own postage, as both are in the same boat, viz., one is desirous of the services of good assistant, the other desirous of a good situation. May I venture to say, as a professional operator of some years' standing, that I am surprised at the treatment received by those unfortunate enough to be out of a berth, and I am one of the many. I, as a rule, pay postage for reply, but very rarely receive one. What becomes of the numerous stamps which never find their way back I leave others to suggest. Should I, by accident get a reply, which surely must be a mistake, everything goes smoothly and plain sailing until the salary is mentioned. Then all is over; the advertiser must either have a fit or drop into a state of coma; and you hear no more. There is nothing like patience. I must say I do not think, as a matter of fact, it is ability, but salary, that causes the trouble. I maintain a good man should be paid a good salary. Why should not the salary be mentioned in the advertisement? It would save a deal of time and expense. As to ability, I cannot be such a dummy, having held a position as head operator and artist with a Royal photographer for a number of years, then with a leading firm in Baker Street, W., and latterly with, I may say, one of the best houses in the North; and yet I cannot secure an appointment. Surely I have not drifted so far away from the professional goal to be so useless, or unworthy of hire; if so, I had better start and enlighten my brains with some other mode of obtaining a living.—I am, yours truly,
JUNE 15, 1905.

PLATINUM PRINTERS' CATARRH.

To the Editors.

Gentlemen,—As bearing upon this subject, I may mention that a number of years ago the late Mr. William Thorp informed me that one of his assistants could not bear what he called "the smell" of platino-chloride of potassium. The symptoms were nausea and severe vomiting. There could be no mistake about the fact; my friend tested it thoroughly.

It would seem that platinum compounds have the fashionable complaint of an "emanation."—Yours very truly,
EDMUND J. MILLS.

64, Twyford Avenue, West Acton, W., June 16, 1905.

To the Editors.

Gentlemen,—The distressing symptoms alluded to by "Old Printer," in your issue of May 26, are exactly similar to my own when working with platinotype paper; in fact, I have given up using it. I tried getting my assistant to cut up the paper, but it made no difference, as, directly I started filling in the frames, no matter how carefully I handled the paper, the sneezing and running at the nose commenced, which made it impossible for me to see customers.

I may add, like your correspondent, it is only in the last two years I have been affected.—Yours truly,
F. S.
Colchester, June 16, 1905.

[This correspondence has now exceeded the space we can devote to it, and we must herewith close it. The following facts obtained

from an authoritative source may be stated as confirming the opinion we expressed—when attention was first drawn to the matter by "Old Printer"—and defining the cause and prevention of the affection:—In a few isolated cases, a species of catarrh, with symptoms somewhat akin to hay fever, has inflicted itself on platinotype printers. The direct cause of this is the dust, or small particles of chemicals, which may arise from the paper, acting on a hypersensitive temperament, possibly equally sensitive to other forms of dust. When such a peculiarity asserts itself, careful attention should be paid to ventilation, and the paper should be purchased in cut sizes, so as to avoid cutting it up, and consequent disengagement of small particles. For this and other reasons, tearing the paper should be carefully avoided. Oxalate powder, if inhaled through the nose, will give effects similar to those complained of. This might occur when making up solutions.—Eds., B.J.P.]

MODERN CHEMISTRY.

To the Editors.

Gentlemen,—My attention has kindly been called by Mr. Clifford E. F. Nash, M.A., to a grave error in my last article on chemical dynamics, in which, by some mistake, I calculated the rate of falling of a body and obtained entirely incorrect results.

The formula, of course, is $s = \frac{1}{2}gt^2$, and the section should read:—In the first second the ball falls 16 ft.; in the second 48 ft., i.e., 64 ft. from rest; in the third 80 ft., i.e., 144 ft. from rest; in the fourth 112 ft., i.e., 256 ft. from rest; and the shape of the curve is to be corrected accordingly.

The example still serves in any case to illustrate the nature of an instantaneous velocity.

I must also thank Mr. Carnegie for his courteous letter. If Mr. Carnegie will refer to the commencement of the series, he will see from the note there that the object of the series was not to explain in any sense the application of physical chemistry to photography, but simply to write a short series of articles on pure physical chemistry. I did, it is true, employ photographic examples, but that was not essential to the argument in any sense. Mr. Carnegie's statement that all reactions are reversible is, I think, true, strictly speaking, i.e., $\overset{+}{Ag} + \overset{-}{Br} = AgBr$. But the equilibrium is so far on the side of $AgBr$ that we may usually, e.g., in analysis, consider it as irreversible, though, in development, it is the reverse reaction which is of importance. I am afraid that occasionally I have implied things which I ought to have stated—but it is not easy to always avoid these pitfalls.—Yours truly,

C. E. KENNETH MEES.

Rylands, Caterham, June 16, 1905.

[For instances of the application of physical chemistry to photographic processes, we may refer Mr. Carnegie to the German photochemical papers, or to the papers at present being published by Messrs. Sheppard and Mees in the Proceedings of the Royal Society, or the "Photographic Journal." The whole work of Messrs. Hurter and Driffeld was based on the principles which have now developed in physical chemistry.—Eds., B.J.P.]

A PHOTOGRAPHIC TOUR IN IRELAND.

To the Editors.

Gentlemen,—For some years past the South London Photographic Society have made a trip to Ireland—an annual excursion. This year they have decided to enlarge the scope of the excursion, and, having succeeded in making good terms with railways, hotels, drivers, etc., are willing to extend their advantages to other photographers who may care to join. I append a list of trips arranged, and shall be

glad to enter into correspondence with anyone desiring to make trip. The excursion is suitable for ladies.

I may mention that the South London Photographic Society will not be acting as tourist agent in the matter, and will not make any profit.—Yours faithfully,

H. CREIGHTON BECKETT.

44, Edith Road, Peckham, S.E., June 17, 1905.

[The itinerary of the tour appears under "News and Notes."—Eds. B.J.P.]

THE SPEED OF TELEPHOTO LENSES.

To the Editors.

Gentlemen,—Mr. C. Louis Hett's article on "The Speed of Telephoto Lenses when Employed on Near Objects" deals with a very interesting subject from somewhat peculiar points of view, and as it is rather difficult to follow his statements and arguments, perhaps the following notes will be of assistance to some of your readers.

When a telephoto lens is described as having an "equivalent focal length" equal to, say, 3 ft., or whatever it may be, it simply means that the telephoto and a 3 ft. "rectilinear" would produce the same size image of a plane object at the same nodal distance. It does not imply that the telephoto acts in the same way as the 3 ft. rectilinear in regard to the matters of exposure, depth, and perspective, and as Dallmeyer pointed out in his "Telephotography," the telephoto lens does not do so with near objects, though it is in all respects equivalent to its "equivalent lens" in the case of distant objects. Assuming both lenses to have apertures of the same diameter, then the telephoto with near objects gives greater depth, and narrower angled perspective, and requires longer exposure. A single-view lens, with stop behind differs in just the same way (though in a very small degree) from a rectilinear of equivalent focal length, but when the stop is in front it differs in precisely the opposite manner, giving less depth and wider-angled perspective, and requiring less exposure.

The variations can all be readily calculated if the necessary data are available, but in the case of the telephoto lens all differences are automatically allowed for by the magnification method of calculating depth, exposure, and perspective introduced by Mr. Dallmeyer, and this method is so commonly employed that many have failed to realise the fact that the results obtained by it differ essentially from those that would be arrived at by taking the equivalent focal length and applying the methods usual with ordinary lenses.

The term "equivalent lens" is somewhat misleading when applied in its ordinary sense to the telephoto lens, or to a single "view" or any other lens of "inconstant aperture." With such lenses the Gauss equivalent lens, though truly equivalent with distant objects, with near objects is equivalent only in the one sense of producing an equal size image of a plane object at a certain nodal distance, but, as I have before pointed out in the "Amateur Photographer" for October 25, 1901, all such inconstant lenses may be considered to have a truly equivalent lens for each different distance of the object. This true equivalent lens with an aperture of the same diameter as that in use will, if situated at the entrance pupil of the lens, produce identically the same results as regards exposure, depth, and perspective.

Though I am not aware that Professor Abbe ever referred to this truly equivalent lens, yet, as it is assumed to be situated at the pupil or Abbe point, I take the liberty of describing it as the Abbe equivalent lens to distinguish it from the Gauss equivalent lens situated at the Gauss point. Its focal length is always equal to that of the Gauss equivalent lens, multiplied by the distance from the entrance pupil of the object plane in sharp focus, and divided by the distance of the same plane from the node of admission. In the case of the telephoto lens the Abbe equivalent lens is farther from the object

an the Gauss equivalent lens, and, in accordance with the rule st given, is therefore of greater focal length. As the effective erture remains of the same diameter the f number, or ratio number the stop, is of course increased. The perspective angle of view is erefore narrower and the intensity is less, while the net result the difference in focal length, measurement of distance of object, e ratio of aperture is an increase in depth.

These matters are all of great theoretical interest, and the varia- ns can easily be calculated, but for practical work the magnifica- on method is the one to adopt with the telephoto lens, as the istence of the variations can then be ignored. With the view lens imilar simple method is not easily applicable, but the variations e so small as to be of little moment, excepting in the case of osure when enlarging. Single lenses are frequently used for larging, but very few workers ever realise that in some cases the e reversal of the lens may increase the exposure by nearly 100 per nt., or that an enlargement of only a few diameters renders e well-known table of relative exposures given by Mr. Debenham e useless with such lenses.—Yours, etc.,

C. WELBORNE PIPER.

June 17, 1905.

BUSINESS ASPECT OF THE COPYRIGHT QUESTION.

To the Editors.

Gentlemen,—There is nothing the British photographer dislikes ore than being done by his customer. Yet hardly a week passes at one or other of us is fooled by some smart person, who comes e photographed, gets proofs, says they are all horrible, has the oofs copied by some cheap firm, and does one or other of us out ur guineas.

May I ask, Sirs, if this is to go on for ever, or cannot something ne done to make the smart ones pay for their smartness?

The Copyright Law says that if a person wishes to have the copy- ght of his photograph he must pay a "good or a valuable considera- on for it."

Is it not time it was decided that the money value of this "good" "valuable" consideration was fixed?

As it is, people imagine that they can go to a photographer in the dinary course of business, get a photograph, and have both photo- aph and copyright, whether they pay for it or not.

I do not know how the case appears to you, Sirs, but to a frog like yself, who sees no fun in the stone throwing, such methods are on par with those of the swindler who orders goods for which he ver intends to pay.

I should like to know whether any photographer has ever had the urage, or the foolishness, to take legal proceedings against any- e who has had photographs taken under such false pretences.

Not only do people have cheap copies made from proofs-supplied- em, but they often have enlargements done from photographs hich they pretend they do not think good enough to order from.

Thanking you in anticipation for inserting this.—Yours, etc.,

FRANK M. SUTCLIFFE.

Whitby, June 16, 1905.

P.S.—It would be interesting to know whether a person who has ot paid a "good, or a valuable, sum" for his portrait, say, £5 or £10, is entitled to the copyright of it. The meaning of the words "good" and "valuable" is plain enough. Would it not be possible r each of us to put a certain value on our portrait work, and state ur price lists that unless we are paid £5 to £10, we retain the opyright in the same?

[The subject of this letter is dealt with in another column.—Eds., J.P.]

Answers to Correspondents.

- *.* All matters intended for the text portion of this JOURNAL, includ- ing queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C. Inattention to this ensures delay.
- *.* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- *.* Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.
- *.* For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

- H. Green, 67, High Street, Dudley. Photograph, Group, Members of Dudley Golf Club.
- G. F. Harris, 123, Queen Street, Cardiff. Photograph, Postcard Reproduction of an Original Oil Painting of the Right Hon. Lord Tredegar.
- A. J. West, Rozel, Villiers Road, Southsea. Photograph of Old Man between two Sailor Boys standing in front of a Wreath where Nelson fell; Bluejacket stands behind them in front of the Ship's Wheel.

N. M. P. S.—The formula appears in our issue of May 19, p. 398.

COPYRIGHT.—I should be pleased if you would kindly answer the following questions for me. I hardly like troubling you on this matter, knowing the number of answers you have given on the subject, but there are still a few things which I am not quite sure about. 1. I am having some postcards printed (from my own negatives) which I have not copyrighted. Could any one else copyright same and thus prevent me selling them? 2. I have seen some of the same views published by a local photographer. If he has already copyrighted his view, can he stop me selling mine? 3. Supposing I purchase a negative from a photographer, can I copyright that and publish it and stop others from copying it?—PRINTER.

1. Certainly not. But why not, before publishing the cards, register the copyright in the pictures, and thus prevent any one from copying them at all? 2. No. He can only register the copyright in his work; he cannot copyright the scene, and you, or any one else, can photograph it from exactly the same standpoint if you like to do so. 3. Yes, if the photographer assigns the copyright to you, and that must be done in writing.

R. SANDIFER.—Thank you, but we do not care to insert the letter. Our stipulation as to name and address is made for self-protection.

B. T. H. (Cardiff).—The idea of the washer is certainly a good one, and based on sound principles. The question is: What will it cost to make? The answer to that decides its commercial success, which, we take it, is what you have in mind. It is not sufficiently better than others on the market to create a demand unless its price can put it at an advantage. We are afraid that the construction makes this impossible.

FILM DRYING FLAT.—Will you kindly inform us through the medium of the B.J.P. a good method of making film negatives dry flat? When dry, they curl up very much, which is a source of great trouble to us.—FILM.

Surely you must be aware of the various non-curling, non-curlable, and anti-curling films now on the market, and extensively advertised in our outer pages. These, being coated with

a thin gelatine film on the back, do not curl up like the old type of celluloid roll film. If you wish to keep flat the films you already have, soak them in glycerine 1 oz., water 1 pint, until flaccid. Then hang up to dry. When dry, place under pressure, and they will remain quite flat in future.

LENS QUERY.—I have a whole plate camera and 11 in. focus R.R. lens and also a 14 by 11 camera but no lens, and I expect to take a few 14 by 11 groups this summer, but do not care to go to the expense of a R.R. lens for that purpose, as I very seldom use that size, therefore I would like to try the supplementary lens. What is the focus of the supplementary lens I should use for my 11 in. focus R.R. lens to convert it into one of 16 in. focus for the 14 by 11 camera? What kind of lens do you consider the best for the purpose, meniscus or what? Now, compare this form of lens with that of a regular R.R. lens of the same focus, and using a stop, say, $f/22$ in each case; what would be the difference between the two in regard to the depth of focus and other qualities?—C. P.

In our issue for February 17, p. 126, appears a note on this subject which gives the very simple rules that will meet every case; but to lengthen 11 in. to 16 a negative lens of 35 in. would be required. A meniscus would be the best form, but, failing this, a plano-concave. It would not be possible to detect any difference between the regularly constructed R.R. and that with the supplementary lens, if both were working at $f/22$, as regards definition, and the depth of focus would naturally be the same.

LICENCE, ETC.—Could you kindly tell me: 1. Is it necessary to have any kind of licence for photographing beanfeast groups, school treats, and similar groups? 2. Is there a living to be made by selling good negatives for reproduction on picture postcards? Could you kindly favour me with the names of any firms who would be open to buy good negatives; or, if this is against your practice, could you tell me of any books where I could gain this information?—JOHN T. WILDMAN.

1. No licence is necessary; but you should first get the permission of the beanfeasters, etc., before you attempt to photograph them, or they may resent it. 2. The postcard market is a very good one at present for reproduction rights. Address the chief postcard publishers with half-plate or larger prints of the subjects you have. There are no books on the subject.

KING.—We will criticise only prints which are properly toned and fixed. When you send these you shall have our candid opinion.

Foco.—The view is one which quite possibly might give the parties the case if they took it into court. We should think your best course is to fall in with their wishes.

EN AVANT.—The cost may vary. "Practical Radiography" (Ward and Isenthal, 6s.) will tell you what is needed for an up-to-date outfit, and Newton and Co., Fleet Street, or Harry W. Cox, Ltd., 1A, Rosebery Avenue, E.C., will quote you and put you in the way and working. We know of no instruction in X-ray work.

W. THOMPSON.—From ferrotype plates, as P.O.P. is done.

C. POWELL AND OTHERS.—In our next.

TONING BROMIDE.—1. When toning bromides by means of hypo alum, why do dark blue-black patches remain, and how can they be avoided (developer metol-soda)? 2. When using ferricyanide, sodium sulphide, I get dirty tarnish marks in the shadows. What is the remedy? 3. Kindly recommend a good book on the subject of bromide working.—CRANK.

1. The dark patches are simply untuned portions of the

original black and white print, and are probably caused by greasy finger-marks. Try rubbing the prints over with a little alcohol on cotton wool before toning. 2. We should like to see the prints, but possibly rubbing with spirit as above will get rid of the marks. See that the prints are thoroughly washed before toning. 3. "Toning Bromides," by Somerville, 1s., and "Toning Bromide Prints," by Blake-Smith, 1s.

CARBONS ON IVORY.—How is a carbon image obtained on ivory for colouring. Have tried single transfer straight on to the ivory, but bichromate stains the ivory badly, and nothing seems to take it out.—CONSTANT READER.

Carbon pictures on ivory cannot be produced by the single transfer method, for the reason you have found. They are done by double transfer. Develop the picture on flexible support in the ordinary way and allow it to dry. Then immerse the ivory and the picture in the following (warm) solution. Nelson's No. 1 gelatine 1 ounce, water 1 pint. Chrome alum (dissolved in an ounce of water) 12 grains. Bring the two in contact, squeegee together, and allow to dry. Then strip off the support.

Gas Explosion at a Photographic Club.—Shortly after a quarter past six on Wednesday evening of last week a gas explosion, attended with serious results, occurred at the Young Men's Christian Association, Grange Road, Birkenhead. The explosion occurred in a small apartment on the ground floor at the foot of the main staircase. This room is set aside for the use of the members of the Y.M.C.A. Photographic Club, who use it as a dark-room for developing their negatives. Throughout the day no member had been there, and the door was kept locked. A member and a caretaker entered the room in the evening, and struck a light. The two men were immediately enveloped in flames, and the explosion occurred. Both sustained severe injuries, which necessitated their removal to hospital. The apartment was completely wrecked, and considerable damage was done to other parts of the building, many windows and doors being smashed.

The fifth Andover Photographic Exhibition will be held on August 7. There will be four open classes, and four open to amateurs residing within a radius of twenty miles of Andover. Particulars will be sent by the Hon. Sec., Mr. W. I. Gradidge, Jubilee House, Andover.

The Photographic Salon is announced to be held in the galleries of the Royal Society of Painters in Water Colours, 5a, Pall Mall East, from September 15 to October 21. Entry forms and full particulars may be obtained from Mr. Reginald Craigie, the Camera Club, Charing Cross Road, London.

***** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

The British Journal of Photography.

The Oldest Photographic Journal in the World.

ESTABLISHED 1854. PUBLISHED EVERY FRIDAY. PRICE TWOPENCE.

TERMS OF SUBSCRIPTION, Post Free.

(UNITED KINGDOM AND THE CHANNEL ISLES.)

One Year ... 10s. 10d. Half Year ... 5s. 5d.

Quarter Year ... 2s. 9d.

Places Abroad (One Year) ... 13s. 0d.

It may also be obtained from all Booksellers, Photographic Dealers and Railway Bookstalls.

EX CATHEDRA.

The prospectus of the fiftieth annual exhibition of the Royal Photographic Society has been published, and we note that although it is in the main similar to those that have appeared in previous years, the particulars and regulations are more concise. The absence of medal awards in the pictorial section, of course, leaves a blank, although the plan of not charging for wall space is again adhered to, and it remains to be seen how the new method of half-price tickets for members and members of affiliated societies will affect the attendance at the exhibition. We also note that with the exception of the announcement in the general regulations that "lantern and stereoscopic slides will be suitably displayed," there appears to be no provision for their entry in the pictorial section, nor yet a separate section for their consideration. The exhibition will be inaugurated on Wednesday, September 20, by a private view, followed in the evening by a conversatione. Further particulars are given in another column.

* * *

Signs are not wanting on every side to indicate that the holiday season has now fairly set in. Holidays, or preparations and speculations relating to the holidays are in the air, and the omnipresent camera is also coming in for its full share of consideration in the all-important question of the holiday season. Indeed, it would be extremely hard nowadays to find a family on holiday bent, amongst whom at least one camera was not to be found. The vast number of cameras and materials that are employed during the holiday season have been forcibly brought to our notice by a recent inspection of the warehouse of one of the leading photographic wholesalers. Stock rooms capable of accommo-

dating many hundreds of cameras of every make and description, and thousands of grosses of plates and packets of printing paper were being emptied as fast as supplies could be obtained from the makers. In the basement hundreds of cases, ranging from boxes half a yard cube to huge tin-lined iron-bound chests, were being packed and loaded on to waiting railway vans, at express speed, and we were informed that this but represented the daily routine during the season. In fact, the demand at this time of year usually far exceeds the supply. Visits to other big wholesale firms convinced us of the truth of this statement, as the same scene was being enacted there also. One pauses in wonderment at the contemplation of the extent of these supplies, the amount of which would stagger the average user of photographic materials. One endeavours to realise the potentialities that are presented by even one day's output by one wholesale firm alone. The miles of holiday exposures, acres of prints, and vistas of exhibition masterpieces, as yet *in nubibus*, would give the photographic statistician a problem of no little proportion, and incidentally afford an excellent clue to the present state of the English photographic market.

* * *

Holiday Exposures.

A contributory cause of many holiday exposures resulting in failure is the lack of attention paid to the subject of changing and packing plates whilst on tour. Many a fine holiday's work has been quite wasted through inattention to this detail. The idea that seems to permeate the brains of many photographers on their holidays, is that having made the exposures, the plates or films can take care of themselves until such time, several weeks, or maybe months, later, when the negatives are developed after the return home. A plentiful crop of fogged, pinhole, scratchy, and light-struck negatives are brought into being, and abuse is heaped on the plate-maker, the camera, the lens, and, in fact, everything but the real cause—lack of proper care after exposure. All brands of plates are admirably packed nowadays, and therefore when slides are being filled all wrapping papers, etc., should be saved, and the plates repacked after exposure, as nearly as possible in the same manner as before being taken from the box. They should be packed in couples, film to film, with nothing between, and each couple should, if possible, be wrapped in oiled tissue paper—of which a plentiful supply can always be carried. The plates are then packed in fours in the original wrapping paper and replaced in the plate box, which is finally tied round with string and a label stuck on the outside containing a number or numbers corresponding to data in the exposure notebook. Both exposed and unexposed plates are perhaps best carried wrapped up with one's clothes in the travelling trunk.

B

Changing Plates on Tour.

It is not always wise to depend on finding a convenient dark-room in which to change plates whilst on tour. Much better be independent and rely on the accommodation afforded by one's lodgings and such accessories as can be easily carried. These need not exceed a small fabric folding ruby lamp, a few cycle candles, and some dark-room pins, unless some trial exposures are to be developed, in which case the equipment can be increased to the extent of some "tabloid" developers and fixer, a couple of celluloid developing dishes, a celluloid measure, and a small folding washing rack, if it is desired to keep the trial negatives. Plates can thus be easily changed or developed in the evenings. No special precautions are necessary to cover the window of the room on an ordinary dark night beyond pulling down the blind, but if it is a "bright" night, or moonlight, or a street lamp is shining into the window, a blanket should be pinned over all by means of the dark-room pins; while a couple of sound blankets carefully fastened over a window with the blind down will usually be found ample protection in the middle of a bright day. In any case the plates should be changed in the darkest corner of the room away from the window. Very little practice will enable the photographer to perform the changing expeditiously, in addition to adding a small number in pencil to the corner of each plate (film side) as it is removed from the dark slide. These numbers should be consecutive and should agree with the notebook record. They will remain on the film after developing, washing, and drying, and thus afford a permanent reference number.

An Outlet for Holiday Photographs.

The majority of holiday photographs—that is, photographs taken during the annual holiday—are seldom seen or heard of again after the exposures have been made. This is perhaps a wise decree of Providence, made on behalf of plate makers and the long-suffering friends of the amateur photographers, who snap away a gross of plates or more as a matter of duty during their three or four weeks' rustication or sojourn by the seaside. Nevertheless, there are other photographers who take their hobby more seriously, and a great many to whom the proportion of satisfactory results to the number of exposures made is a prime consideration. It is strange, however, that these photographs, often of topical and pictorial value, are not turned to account to the pecuniary advantage of their producers. A collection of good holiday snapshots of an interesting character submitted to the illustrated papers will often result in a goodly crop of half-guineas, that will do much to intensify the photographer's interest in his work, to say nothing of making the annual holiday an extremely cheap one. Of such papers, a high-class production, such as "Country Life," offers the best opportunities for holiday subjects of general interest. Photographs dealing with striking incidents of the countryside and topical events in the world of outdoor sports and pleasures always meet with full consideration at the hands of the art editor, and the reproductions in this particular paper are probably as fine as half-tone work for periodical illustration well can be.

A Penny Camera Outfit.

Since the existence of a halfpenny set of printing materials was brought to our notice we have had our attention drawn to a more serious and determined effort to draw the youthful population into the photographic net. Camera, plate, and chemicals for a penny! The proposition, made in the window of a sweet-shop, is not a mere catch-line to entice

the passer-by into purchasing the "Weekly Home Blitherer," or some other product of decadent journalism. For one penny you positively obtain a pinhole camera (and no mistake about the pinhole, which is evidently the result of a sharp prod into the cardboard delivered with a hatpin at the rate of eighty a minute by a robust young woman), one plate, developer (two solution), hypo, and a sheet of instructions. We can quite endorse the appeal in the latter not to make the pinhole larger—it is quite large enough. The instructions are accurate and inspiring, e.g., the following:—"A Ruby Lantern for the dark-room is often wanted. Boys, you can make one by cutting a hole in the side of a wooden box, and pasting a sheet of red paper over the hole, and placing a small lamp inside the box." But we will not anticipate the pleasure which our readers may wish to extract for themselves from the maker's circular.

Printing Without Light.

Professor Otsuki, when reading his recent paper on the action of hydrogen peroxide on a photographic plate before the Society of Chemical Industry, exhibited some remarkably good copies made by a modification of Ostwald and Gros's katatype process. They exposed the negative to peroxide vapour, instead of treating it with the aqueous solution. In the full text of the paper now published the method of making the copies is described:—"An ordinary photographic negative is exposed to an aqueous solution of the peroxide, and then, in the dark, is pressed closely against a photographic plate in a printing frame for some time. At the dark parts of the negative the condensed hydrogen-peroxide is decomposed catalytically by the metallic silver, where it is absorbed by the gelatine of the clear parts of the negative without decomposition. A latent image of peroxide is thus formed, and is transferred to the second plate, producing a positive image on development. In like manner, the latent peroxide image can be transferred to plain or gelatinised paper, and either may be treated with some salt, which is easily oxidised by the peroxide, producing a positive image of oxidised salt on the paper. Thus, a ferrous salt produces a faint image of ferric salt, which is changed to black with a solution of pyrogallie acid.

Shrinking Cameras in Hot Weather.

Users of hand cameras occasionally find that their negatives are not so sharp as they should be, while at other times they are perfectly satisfactory, although the lenses are in all cases set to the scale marked upon the camera. A case of this has recently been brought under our notice and the details of it may, just now, be of service to some who use cameras of the cheaper kind, which are furnished with lenses of large aperture. The camera was a cheap one of the box form, but the lens with which it was originally fitted had been replaced by one of a more expensive kind working at $f/6$. This had been done some time ago. A focussing scale was marked upon it, not by calculation, but by trial and error, and all went well until quite recently. The cause of the trouble was not suspected until we found that when the lens was adjusted according to the scale, the camera had to be racked a little inward to obtain a sharp negative. Now the cause was obvious, the wood of the camera had shrunk from its original dimensions at the time the scale was adjusted, sufficient to throw a wide aperture lens out of its best focus. Box-form cameras are generally built with the wood cross-wise of the grain as regards the longest dimension (the length) of the instrument. It is

well known that the expansion and contraction of wood is greatest cross-wise of its grain. Some woods, indeed, will contract more in the width of a twelve inch board than they will in eight or ten feet in its length. With these facts before us it is easy to see that a rigid camera with the scale adjusted early in the year, perhaps after it has been unearthed from a damp room where it was stored for the winter, would, after being carried about in the sun during summer weather, contract sufficiently to throw a large aperture lens out of its sharpest focus, more especially if it were worked with a large stop. In the case of a single lens, or one with a small aperture, the loss of sharpness due to the shrinkage of the wood would pass unnoticed, and it is only when lenses with large apertures are employed that the trouble becomes manifest. With a lens of, say, five and a half inches focus, such as is usually employed with quarter-plate hand cameras, worked with an aperture of $f/6$, a difference of a sixteenth, or even a thirty-second, of an inch would very materially interfere with the sharpness of the image.

* * *

High prices for engravings. There is, we think, little question that photogravure has enhanced the price of engravings by the older engravers. Indeed it seems to have almost killed the old style of line and mezzotype engraving. The old engravers have died and there are, practically, no new ones to take their places, hence it is that where fine impressions from the plates of the old artists come into the market they usually fetch high prices. For example, at an auction sale (Christie's) one day last week there was a keen competition for the twelve colour prints "The Months," by Bartolozzi and Gardiner, after W. Hamilton, R.A., and they were knocked down for £162 15s. A pair of prints "Guinea Pigs" and "Dancing Dogs," by T. Gauguin, after Geo. Morland, made £136 10s. Valentine Green's four print "George Washington" sold for £131 10s. "The Birth of a Heir" and the "Christening," by Biggs, after W. Ward, realised £298. It is noteworthy that these fees were all paid by picture dealers. Two or three days later, at the same auction rooms, a small collection of water colours and oils were sold, and the day's sale realised just upon £19,000.

* * *

Industrial Alcohol. Some time ago we made a few comments on the report of the Committee appointed to inquire into the desirability of permitting the use of duty-free alcohol for industrial purposes, so as to enable manufacturers here to compete, commercially, with those of certain refined materials produced in other countries, where, for manufacturing purposes, duty-free spirit is allowed. At the time our comments were made we expressed the hope that Government would take a favourable view of the subject, and permit the use of duty-free spirit for industrial purposes. If that were done, it would be of some benefit to photographers, though to the extent it would have been when the collodion process was the one universally employed for negatives. The liquid constituents of collodion consist of about equal parts of ether and alcohol, and the latter is, roughly, three times the price of the former, owing to the duty upon it, whereas, if there were not that duty, it would be less than a quarter of the price of the ether. This would mean a very material reduction in the cost of the process. Wet collodion is not yet so obsolete as many may imagine. It is still used almost exclusively by process-workers and those who supply enlargements where an enlarged negative is necessary, as in the

carbon and the platinotype processes. To such, and still more to the makers of collodion papers, the price of collodion, is a material consideration. The Bill, now before Parliament, to deal with the industrial employment of pure alcohol, is drawn up on the lines recommended by the Committee which recently presented its report. Thus the Bill adopts one-nineteenth of denaturant in methylated spirit instead of the one-ninth in vogue at present; it provides for the use of industrial spirit without payment for Excise supervision; it proposes the removal of the surtax on wood-spirit; and it promotes greater facilities for the sale of mineralised methylated spirit.

* * *

A Proposed New Spirit.

At present methylated spirit contains ten per cent. of wood naphtha; if the Bill passes it will contain but five per cent. Five per cent. of wood naphtha in the alcohol used for collodion would not be harmful, provided the naphtha were fairly pure. But hitherto the Excise authorities would not allow of that; every sample has to be submitted to them before it is used, and if it is at all refined it is rejected for the purpose. The greater proportion of the collodio-chloride paper used in this country comes to us from Germany, and there the methylated alcohol only contains five per cent. of naphtha, and that of a purer kind. There special alcohol for manufacturing purposes is a regular thing, but whether this or the five per cent. methylated is used for chloride paper we cannot say. But if the small proportion of naphtha were tolerably pure the one kind would be, for this purpose, practically as good as the other.

* * *

Poisonous Cerium Salts.

It would be easy to prolong a list of substances of photographic importance which are strong poisons. In fact there are few photographic "chemicals" which can be called comestible bodies; they are all injurious if you take enough of them. But as the photographer is accustomed to use, not to imbibe, the solutions, one has no need to trouble his head with the toxicology of pyro or mercury. It is important, however, that he should be warned of possible harm in the ordinary use of his materials, and that is the point of view we have taken in the short series of chapters on poisons which concludes this week. As we end our notes we see the announcement of the poisonous properties of cerium salts, which are stated to resemble those of lead or antimony in their effects. The antidote is a weak solution of an alkali which precipitates the cerium as an insoluble hydrate.

* * *

Seasonable Display.

It is well known by those who have made great commercial successes that the capture of the eye is the chief thing. We referred a week or two ago to the evils following the production and output of "good photographs," pointing out that the excellence of the technique was only a part, and a comparatively less important part, of photographic business. The effect of this on the window or showcase display is also to be considered. Merely because the specimens are still good prints is no reason why they should remain on view. The thoughtlessness in showing portraits in furs during the dog-days is not merely irritating, but is bad business. The lady in a summer muslin will be much more tempted to patronise the establishment if most of the specimens are of ladies and children in white or light dresses, the prints made in the cool grey of bromide or platinotype, and mounted on light boards. The setting of

the display, too, is most important in its reflex action on the mind of the possible customer. Dirty and faded red plush, with a score or so of dusty dead flies, inevitably suggests that the studio and dressing room will be in the same unpleasant condition, and the whole prospect becomes repugnant at once. Another order is lost.

* * *

Canadian Photographic Manufacturers

A visit is now being paid to this country by a party representing the Canadian Manufacturers' Association, a body formed to forward the interests of Canadian industries, and consisting of 1,800 members. According to some statistics, given by the secretary to an interviewer, photographic materials in the colony are in the hands of nine establishments, representing a capital of about £24,000, and producing an output to the value of £46,000. These concerns are said to employ 96 people, and to pay them £6,376 annually in wages. Canada is making great strides in chemical industries, and does not confine its manufactures to soap, glycerine, ammonia, and similar products, but is putting refined chemicals, textile dyes, and other highly manufactured articles on its own and possibly other markets.

POISONS USED IN PHOTOGRAPHY.—III.

IN the two previous articles we dealt with some of the more important photographic poisons having an injurious action on some persons who employ them. There are still a few more that must be referred to. In regard to metol, in the first place there is no question that, with some persons, it produces very unpleasant effects on the skin of the fingers and hands. Indeed, some workers have had to entirely to relinquish its employment solely on that account useful as it would be to them. Its action in some instances—and the early symptoms particularly—are not altogether unlike those of bichromate of potash—an irritation on the backs of the fingers which develops into a kind of subcutaneous eruption on the parts with, later on, a drying or peeling of the skin. Metol appears to take effect—where effect is taken—in a much shorter time, and with less use of it, than does bichromate of potash. A useful allayer of the irritation is the carbolic lotion given on p. 383 ante.

The ill effects of metol can be more easily avoided than those of the bichromate, inasmuch as, with neatness in working, the solution need not come in contact with anything but the inner extreme tips of the fore fingers and thumbs, either in the development of plates or papers, and they, by reason of the thickness of the skin at those parts, are not likely to become affected. The fingers need not be put into the solutions at all. The plate, or paper, can be raised from the solution—for years we have used a quill toothpick for the purpose—then, in the case of plates, they can be held at the corner or edges by the forefinger and thumb, sloping downward, so that while they are being examined the solution drains off into the dish instead of into the palm of the hand and between the fingers. India-rubber finger stalls of extreme thinness are sold at the photographic warehouses. They are so thin that they cause no inconvenience in working, and they effectively prevent the solution coming in contact with the fingers, and they are quite inexpensive. In the days of the wet collodion process it was easy to distinguish the neat from the slovenly worker, after the day's work was done, by the silver stains on their hands. The former would only have the insides of the fingers and thumb of the left hand and the two forefingers and thumb of the right one badly stained,

while the latter would have the backs of all the fingers and hands, sometimes also the wrists, badly stained. Similarly would this be the case with many workers with metol and the other developers if they left the tell-tale stains which are unavoidable in working the collodion process.

Bichloride of mercury is a deadly poison if taken internally, but despite—or perhaps we should say in consequence of—repeated cautions, we have not heard of its solution having an injurious action on the skin, or ill effects on the system. In the previous article of this series we referred to a recent note in "Wilson's Magazine" in which the writer speaks of salivation being caused by working the platinotype process for brown tones, due to the bichloride of mercury, and it will be remembered that we expressed ourselves dubious on the point. Bichloride of mercury is largely used in the intensification of negatives, and no case has come under our notice of any inconvenience arising therefrom. As a matter of fact, a very weak solution of the bichloride is frequently employed as a dressing for wounds after surgical operations. In the practice of the Daguerreotype process the operators were somewhat freely exposed to the vapour of mercury in the development of the image, yet we have not heard that it had any serious result upon them.

Formaline is said to have a hardening action on the skin, causing it, after a time, to crack and the fingers to become sore. It is easy to see that such may be the case when it is largely used. We all know its effects on gelatine, and the skin, after all, is but untanned leather, or gelatine.

It is a curious thing in connection with those substances which affect the skins of some persons that it is not always the, to all appearances, most delicate skins that are the most readily effected by them. We may mention that one worker of the carbon process who has worked it daily for the past couple of decades or more has a most delicate-looking skin, yet he has never suffered the slightest inconvenience from the bichromate of potash, while, on the other hand, others we know with apparently thick and robust skins have suffered badly from it with less than a year's working.

In bringing these articles to a conclusion, it may be asked if the chemicals used in photography are really so injurious as some would have us to believe? That the bichromates are, when largely used by some persons, is beyond question, and the same may be said with regard to metol. But in many instances even these substances get credit for more than is actually due to them. It often happens that some one breaks out in a slight rash on some part of the body, or has some little ailment he cannot account for. The local "medico" is consulted, and diagnoses the case, which may be a very simple one. But not infrequently the patient asks, after explaining that he practises photography, if it is likely that the poisonous chemicals he uses is the cause of the trouble. The reply sometimes is that it is possible that they may have had something to do with it. The patient, after what he may have previously read, at once jumps to the conclusion that the chemicals are the cause, and probably promulgates the idea among his acquaintances.

Still, in dealing with chemicals of a poisonous character, it is always wise to guard carefully against any possible ill effects from them. This may be done by making it a rule to always well wash the hands with plenty of soap and water, preferably warm water, after the operations are completed. As a last word, it is our opinion that, with the exception of metol, used without care, there is no chemical used in photography, on an amateur scale, from which the worker need be in fear of suffering any ill effects.

PHOTOGRAPHS IN COLOURS FROM NEGATIVES BY THE LIPPMANN PROCESS.

(A Paper read before the Paris Academy of Sciences.)

The following note relates to the well-known method of reproducing colours by the exposure of a sensitive transparent film backed with a reflecting surface of mercury. The colours are visible by reflected light when the plate is developed. It is known that the nature of the sensitive film is immaterial to the process; it can be gelatino-bromide of silver, or bichromated gelatine, albumen, or cellulose.*

When the sensitive surface consists of a bichromated film, it is fixed by simply washing in water; the colours then make their appearance, even while the film is still wet. They disappear on drying, to reappear again and again every time the film is wetted.†

The above phenomenon is doubtless caused by the hygrometric properties of the film. The bichromated body becomes less able to swell in water wherever the action of the light has been greatest, i.e., in the maxima of interference. Moisture renders the plate heterogeneous, in an optical and physical

* When employing cellulose, the process is as follows:—The cellulose is dissolved in Schweizer's solution and thus applied to a glass plate. When the film has been obtained, it is decolorised by washing with dilute hydrochloric acid, soaked in a three or four per cent. solution of potassium bichromate and put to dry. It is then exposed in the mercury dark-slide until a faint brown image is obtained, and it then only remains to remove the bichromate, washing the plate in pure water, when the colours appear.

† (Schweizer's solution, here recommended by Professor Lippmann, is a saturated solution of freshly precipitated copper hydroxide, $\text{Cu}(\text{OH})_2$, in 20 per cent. ammonia.—E.S. B.I.F.)

‡ In the case of gelatine which swells greatly, the plate should not be completely wetted, but should be dampened only with the breath or with alcohol.

sense, by breaking up its surface according to a periodic law, and the question arose in my mind whether this transitory effect of moisture could not be permanently replaced by that of a solid, stable body.

I soaked the plate in a solution of potassium iodide instead of in pure water. On drying, the colours were visible, though feebly so. The potassium iodide thus remained in the film, unequally distributed between the maxima and minima of interference. On proceeding to pour over the dry iodised films a solution of silver nitrate (20 per cent.), the colours became extremely brilliant, and, on drying the plate, lost none of their striking character.

There is no doubt that silver iodide is formed in the film, and is unequally distributed throughout the thickness of the coating. But it remains transparent, in a state of pseudo-solution, in the solid film. It has no other effect than to produce an intensification of colours, persistent after drying.

It will be seen also that when viewed by transmitted light, the complementaries of the colours are observed, and these negatives are extremely brilliant. Should it be possible to obtain the same result, not from bichromated films, which are feebly sensitive and isochromatic, but from gelatino-bromide films, the problem of multiplying prints in colours in the ordinary way in a printing frame would be solved.

GABRIEL LIPPMANN.

PHOTOGRAPHERS' ADVERTISING.

The following contribution from a photographer by no means unknown in professional circles is written after perusal of the recent articles in these pages on the same theme (THE BRITISH JOURNAL OF PHOTOGRAPHY, March 24 and 31, and April 7, 14, and 21). Though the writer has the same object before him—the local advertisement of a photographic business—the suggestions he makes run in quite a different channel, but one of which certain men can make effective use.

The subject of advertising deserves the greatest attention on the part of professional photographers, for in these days of commercial competition it is necessary to keep one's business constantly before the public mind to secure recognition; but, while the ordinary methods of obtaining publicity, which have been so ably expounded, are worthy of due consideration, there are other methods which, under some circumstances, are equally efficacious.

Professional "Advertising."

When one, as a stranger, settles in, or visits for a time, a town, how soon it is that one learns the names of some of the local doctors, solicitors, dentists, and others, and even knows them by sight, even although in their business capacities one has no occasion to hold personal communication with them. Doctors, lawyers, and dentists are not allowed to advertise directly, so they at least cannot thrust their names forward through ordinary advertising channels, yet they do manage to be very successfully, to get themselves and their businesses known so thoroughly that even strangers to a town are very well acquainted with their existence. The advertising pages of the local paper are innocent of their names, but the pages of reading matter bear frequent testimony to their doing something or other to bring them in prominence and to make themselves generally known to all sections of their fellow townsmen. It is not entirely altruism that induces men to spend their time and energy doing the unpaid work of the community.

From Members of Parliament and county magistrates downwards to the officials of the local debating society, every one expects a return of some kind for his services—not necessarily a pecuniary gain, but something that is equally valuable—social distinction. Lawyers, doctors, etc., gain both by busying themselves with public affairs, for their business is of a kind which is almost inseparable from the personality of the individual. They are generally keenly alive to the fact that people will go to a professional man of whom they know something on a matter they would hesitate to take to a stranger. A photographer's business is often very much on the same lines—a personal business; and many of his customers do not merely go to his place of business, but they go to him personally. Moreover, photographs are not in any sense necessities of life, and people want reminding that they want them. The more the photographer mixes with his fellows, the more frequent the reminder.

Business via Social Intercourse.

In every town there are always many groups of persons who form themselves into communities for various objects. The churches and chapels, with their social reunions, the cricket, football, and golf clubs, the natural history, microscopical, photographic, and choral societies, and others too numerous to mention, all may be converted into happy hunting grounds by the photographer who is not afraid of spending a little time and money on the pursuit of fresh business. The subscriptions are usually quite small, and easily recouped by a very few orders. It is not necessary to take a very active part in the proceedings of any of these communities to become known by the members. The display of a little tact and the show of some interest in the particular pursuit are quite sufficient to make acquaintances, and every acquaintance is a possible—even a probable—customer. The cricket club, if it wants a group,

will rather employ their member, Mr. Camera, than an outsider, and every member who sees a print will feel increased interest in it because it was done by a fellow-member. People who are quite unapproachable in the ordinary way descend from their altitudes in the pursuit of their hobbies, and then is the opportunity for the enterprising member of the particular community who happens to be a photographer to do a little indirect advertising.

"The Quality of Mercy is Not Strained."

A few pounds spent on charitable or semi-charitable objects are not ill-spent under any circumstances; when the subscription of a few shillings to an object deserving in itself also secures a line in the subscription list published in the local paper, the benefit to the receiver is not lessened because the donor may be advantaged. It is an advertisement he is legitimately entitled to, and he will be making no more use of his charity than the majority of those whose names appear above and below his in the list.

It is not to be supposed, however, that every photographer can become an individual of prominence. It depends upon the

manner of man he is, the locality of his business, the class of trade he does, and other things. The value of doing so depends upon his ideas of photography as a calling. If he look upon it merely as a manufacturing trade, the puff direct will serve him best; but if he treat it as a profession, that his productions are imbued with his own personality, in making himself known and appreciated he will make his work known and appreciated. Unfortunately for themselves, professional photographers as a class are characterised by an unaccountable aloofness. They are sometimes too socially disposed in some directions, but generally too little so in directions which would be more profitable. In other professions there are rigid codes of professional etiquette designed to prevent illegitimate competition. The photographer, unrestrained in this way, too often seeks to increase his business at the expense of his brother's, instead of making fresh business for himself. In the ridiculous warfare which ensues the object of it is often forgotten, and both sides lose. It should be the aim of all to increase the general demand for photographs, and he is the most successful advertiser who convinces people that they want the articles he is prepared to supply.

CASUIST.

A FIXATIVE FOR CRAYON AND PASTEL WORK.

PROBABLY the greatest drawback to finishing enlargements in pastel has been the extreme difficulty of fixing the work so that it does not smudge or easily rub off. The material has such a delicate hold to the paper surface that a mere flick with a duster is often sufficient to completely smear the picture with streaks of pastel powder.

Crayon artists who have never tried fixing pastels on photographic bases may probably doubt the existence of the difficulty, as there are on the market various "fixatifs" for fixing crayon work. They are, unfortunately, totally unsuitable for photographic work, as they dry over a gelatine film with a more or less patchy and glossy surface, totally ruining the work.

Again, a fixative which will do tolerably well for a rough paper is useless for a smooth one. I have tried diluting the "fixatifs" on the market so as to make them dry flatter, but the result is unsatisfactory. After making extensive experiments with various gums, gelatines, etc., and many diluents, I have settled on a formula which gives very good results on both rough and smooth papers, and can be safely used without fear of spoiling either the enlargement or its mount, the latter being quite as essential as the former, for it is impossible to cover it so that the fixative will not travel on to it. When perfectly dry, it will stand dusting and practically as much rough usage as a water-coloured enlargement would do.

The Perfect Fixative.

In order that the reader may understand the difficulties in the way of making a perfect fixative, it may be as well to point out the necessity that the preparation used should not discolour the enlargement or its mount; should not dry glossy, white, or patchy; should not form tears or spots; should dry quickly, and not carry off the powdered pastel—or, in other words, remove the work. In connection with this latter point (which will remind the retoucher of the trick some negative varnishes have of removing retouching), I found that by far the greater proportion of compounds used removed part of the work, and so were useless.

Fixative Constituents.

Of the most suitable bases for making a fixative may be mentioned mastic and celluloid. The former is more useful than other resins or gums on account of its greater hardness combined with elasticity. Mastic is partly soluble in alcohol, methylated spirit, or ether, but a tenth part of it (which

gives it its elasticity) called masticine, is insoluble therein. I find that amyl acetate dissolves the mastic acid, and also has some effect on the masticine, for a clear and bright solution can be effected with but little precipitation. The two, therefore, used together make a fairly passable fixative, but disposed to deposit in fine string lines and rings, whilst if ether, alcohol, or methylated spirit is used instead of amyl acetate, whitish crape-like markings are apt to make their appearance, as also they do if a fixative composed of celluloid, alcohol, and ether is used, unless it is made so strong in celluloid as to cause it to dry glossy. Celluloid and amyl acetate would do admirably but for its disposition to remove portions of the pastel-work; but by combining them with mastic we get a satisfactory result.

The Formula.

No. 1.

Mastic	24 gr.
Amyl acetate	3 oz.

Dissolve by agitation, and allow to stand some hours before use.

No. 2.

Celluloid (film clippings free from emulsion will do)	7 gr.
Amyl acetate	3 oz.

Dissolve by agitation, and when No. 1 solution is clear, mix both together, and keep for use in a short-necked and tightly corked bottle.

How to Apply the Fixative.

Procure from the artists' colourman a spray diffuser, which is composed of two little pipes, which when opened out for use are at right angles to each other. Place the picture to be fixed in a vertical position, and then insert the end of one of the pipes (the finest one, and made of metal) in the bottle of fixative. Put the other, and larger, tube to the mouth (which must be emptied of saliva and the lips dried), blow through it in the direction of the enlargement, which should be about fifteen inches away. The fluid will be brought up through the smaller pipe and sprayed on to it. Direct the spray to the upper edges of the photograph, and then work across and down as rapidly as possible, and using only a very small quantity of fluid, otherwise it will run in unsightly tears down the mount. But in applying it is best to cover the entire enlargement, and not only the part worked up, as in

course of time the part not covered may yellow more readily than that which is fixed.

When covered, dry the enlargement by waving in the air, and also rotate it so that the fixative does not dry in curves. If it does it will leave unsightly glossy lines, and although these may be removed by dabbing (without rubbing), using cotton wool moistened with amyl acetate for the purpose,

yet it is far better to avoid having to do so. When surface dry, it should be allowed to stand by for an hour or so to harden, and then it can be subjected to any careful handling without risk of damage, and if properly done it will be found that the fixative has dried in a way so that it is impossible to tell without rubbing whether the picture has been fixed or not.

ARTHUR WHITING.

PSEUDO-PHOTOGRAPHY.

IN 1897¹ Dr. W. G. Russell first described the peculiar phenomena which occur when certain metals or non-metallic substances are placed in close proximity to gelatino-bromide plates. In the following year, at the British Association meeting, he advanced the statement that the results were due to the vapour of hydrogen peroxide, and in a later paper² he shows that one part of the peroxide in one million of water will produce a developable image, and that blotting paper and other substances impregnated with the same and dried will also affect a plate; further, that all bodies which are opaque or transparent to the emanations from metals and terpenes are opaque or transparent to hydrogen peroxide. Experiments are detailed which show that all organic bodies that can act on a plate are capable of giving rise to peroxide when they oxidise in moist air.

The question as to how the peroxide passes through such substances as gelatine, celluloid, goldbeaters' skin, parchment, &c., is answered by Dr. Russell in effect:—"Not by the ordinary process of diffusion, for hydrogen cannot diffuse through it (gelatine), so that it must be by a process of dissolving, or very feebly combining with the medium or with constituent of it, and thus travelling through, escape on the other side." To explain the action through celluloid, Dr. Russell shows that whilst camphor itself is a non-active body as regards the plate, yet it can absorb the emanations from hydrogen peroxide, zinc, copal, &c., and can then affect the film, and he says:—"Thus the camphor, which is a principal constituent of celluloid, may enable hydrogen peroxide to pass through it. Gutta percha and indiarubber also permit the passage of the emanations, and they are said to be allied in construction to camphor, and thus their action is explained."

Another interesting experiment by the same author shows that absolutely dry zinc placed in chloroform, ether, and alcohol showed no action, but that on the introduction of the minutest trace of water, such as the very thin film adherent to a small glass rod, the zinc became active. Further, bright zinc oil imparted activity to inactive benzine and petroleum spirit.

At the meeting of the British Association already referred to, H. Bothamley³ referred to cases in which images previously impressed on dry plates by light were destroyed by vapours given off by printers' ink, the material of the hinges of dark slides, &c., and that these vapours were capable of passing through paper. Sir Wm. Abney showed that solutions of hydrogen peroxide will destroy a latent image, and therefore Bothamley states that "combining these results with Russell's, it follows that hydrogen peroxide, acting in small quantities for a short time, will produce developable images, but acting in a larger quantity or for a longer time, will destroy the images previously produced by light." This is confirmed by some interesting experiments carried out by Luppö-Crämér in 1902,⁴ as will be seen below, but it is as well to record that Le Roy⁵ in 1894 showed that hydrogen peroxide solution rendered strongly alkaline would act as a developer.

Luppö-Crämér's experiments were carried out by cutting plates into narrow strips and immersing them to half their length in hydrogen peroxide solutions in test tubes, and then washing and developing. Experiments with collodion emulsion plates gave negative results, and it would therefore seem more probable that it is not the silver bromide which is affected, but the "gelatino-bromide of silver," and that hydrogen peroxide therefore belongs to those substances which destroy the union between the gelatine and the AgBr molecule, and reduces the latter to the reducible state in which it is met with when precipitated.

The want of action on collodion plates apparently refutes the suggestion which Chapman Jones⁶ states he made in 1898:—"That as all the active substances experimented with in this connection were susceptible of oxidation by mere exposure to air, and as during their vigorous oxidation (combustion) a form of radiant energy which will affect a photographic plate was certainly produced, it might be that the slow oxidation produced a similar form of radiant energy, just as the total heat effect is supposed to be the same whether the oxidation is slow or rapid. I pointed out the relatively enormous exposures given in Dr. Russell's experiments. One ten-thousandth of a second is certainly ample time to produce the developable condition in the silver salt of a gelatine plate when it is exposed to burning zinc, and it seems not unlikely that an exposure of, say, six hours to the slowly oxidising metal should produce a similar effect, for this increase in the time of exposure is equal to the increase of from one second to more than six and a half years."

Luppö-Crämér gives the following tabular statement of his results:—

Per cent. H ₂ O ₂ .	Dipped Half.	Free Half.
·0001	Slight action.	None.
·001	Considerably stronger.	None.
·003	Very strong.	None.
·01	Stronger than last.	Slight action.
·1	Slightly stronger than last.	Marked action.
·3	Less strong.	More than the dipped half.
1·0	Slightly less strong.	Complete reduction.
3·0	Perfectly clear; no action.	Complete reduction.

The author suggests that solutions between 0.03 and 1.0 per cent. may be said to give an appearance similar to the neutral condition of light solarisation, whilst with 3 per cent. complete reversal by chemical means is produced.

It is also pointed out that it is only hydrogen peroxide in the neutral state that causes this action—acidulated, it apparently has no effect—and that there is no veiling with alkaline peroxide. Ammonium persulphate acts in precisely the same way as the peroxide, only more slowly, as also does sulphuric acid, therefore it is an open question whether peroxides or persulphuric acid are not present in sulphuric acid.

Graetz,⁷ in 1903, advanced the theory that the Russell phenomena must not be ascribed to the primary action of the per-

oxide, but rather to "rays" analogous to the well-known Becquerel rays, and compared the formation of the hydrogen peroxide to the formation of ozone by Becquerel rays. That the active agent is not ozone would appear to be proved by the experiments of Villard,⁸ which showed that in its pure state ozone had no action on a gelatino-bromide film, but if paper, aluminium, or bismuth were placed near the film, then there was action. This was confirmed by Dony-Hénault,⁹ who found that ozone only acted in the presence of easily oxidisable bodies, and he ascribed the action to the formation of hydrogen peroxide.

The subject is further complicated by later researches of Graetz,¹⁰ in which it was proved that the action took place when a strong stream of air was blown between the peroxide and the film. Russell also had pointed out, 1898, that the "vapours" can be carried along in a current of air, and will act on a plate on which the air impinges. Further experiments by the same author showed that action took place even when the film was not exposed directly to the peroxide, but with the plate reversed, and that a piece of metal on the film gave a lighter image of itself than the unprotected part. On the other hand, certain liquids, such as ammonia solution, alcohol, and water, produced a stronger action, whilst petroleum and turpentine gave a weaker action than the water. One might be tempted to interpolate the query as to whether this might not be due to the gelatine being rendered more permeable to the developer, only this would not apply in the case of alcohol, and a curious phenomenon of marginal action was

noted, for when the action was generally lighter, the margins showed still lighter, and when darker, the margins were darker. A possible explanation of this in the face of accurate measurement is the question of contrast, as when looking at an H. and D. strip precisely the same appearance is seen, but Graetz also suggested that in all probability it was due to small differences of temperature, as a glass vessel filled with warm water placed on the glass of the plate gave a lighter image, whilst one filled with ice gave a darker one.

Precht and Otsuki¹¹ explain away Graetz's assumption of a radiation effect by proving that in all cases where action by hydrogen peroxide was found, the presence of the peroxide could be detected on the film by means of titanium-sulphuric acid, and they come to the conclusion that the action must be ascribed to the condensation of hydrogen peroxide on the film.

Schaum¹² explains the absence of action of ozone as being due to the different sensitiveness of plates, and to the different behaviour of the gelatine used in preparing the plates. He further states that ozone acts even when there is no readily oxidisable body present, and when, therefore, peroxide cannot be formed, which is directly opposed to the observation of Dony-Hénault, cited above.

It may possibly be permissible to draw attention to the fact that Von Aubel¹³ has pointed out that the peroxide from turpentine, etc., acts on the electric resistance of selenium cells in exactly the same way as light, and that these notes are an append to those on Prof. Otsuki's paper in the B.J. for May 5, p. 342.

THE WEEK IN HISTORY.

Progress in Emulsion Making.

"PELLICLE" and "pellicular films" are common words in the literature of sensitive materials during the seventies. The term originated, I believe, with the "pellicle" of Mr. Kennett ("The Week in History," June 16), but a number of other workers were intent on perfecting a dried emulsion. One notable paper is that of the late Colonel Stuart-Wortley, published thirty-one years ago to-day in THE BRITISH JOURNAL OF PHOTOGRAPHY. In making his emulsion, Colonel Wortley departed from previous methods in working at a high temperature (180 deg. Fahr.), with the object of forming the emulsion quickly. "Pellicle films" innocent of glass were aimed at in these experiments, and favourable reference is made to flexible films, thick and thin, of gelatine only. I suppose there are still many photographers living now who have clear recollections of the early days of gelatine, and the fiery discussions which emulsion questions aroused at the (then) Photographic Society of Great Britain, now the Royal Photographic Society. I well recollect the passages at arms working at the late Colonel Stuart-Wortley and Mr. Kennett anent priority of emulsion inventions. Colonel Wortley's temperament might be fairly described as "peppery," and his connection with the Uranium Dry Plate Company incited him to contest the rights of other inventors more keenly than he would have done in his private capacity. But the London Society has always been tenacious of life, and the rows of those days were not able to break it up.

The Waterhouse Stop.

One of the questions which I imagine is frequently put to Major-General Waterhouse, the present President of the Royal Photographic Society, is: Are you the inventor of the Water-

house diaphragm? The answer is, No, for it is exactly forty-seven years ago that a namesake of General Waterhouse's, one John Waterhouse, of Halifax, gave a description of this form of stop in a letter to the Society. His suggestion was made in reference to portrait lenses, and was published with an illustration in "The Photographic Journal" for July 21, 1858.

The first Waterhouse stops fitted by some of our opticians had a hinged cap over them to prevent the light gaining access between them and the slot in the mount. But afterwards, with neater work, this was found unnecessary. Prior to the introduction of the Waterhouse stops the stops—usually one, or sometimes two or three—were fitted in the hood of the lens and were pushed quite close up to the surface of the front combination—obviously not their best position.

Panoramic Photography Sixty Years Ago.

To-day, precisely sixty years have passed since the first panoramic camera was exhibited to the French Academy of Sciences by its inventor, M. Martens, who explained this application of the Daguerreotype process. The construction of the instrument was based on the horizontal turning movement of the lens over the whole horizon, the image being received on a sensitive Daguerreotype plate bent to a circle, with radius equal to the focal length of the lens. A vertical slit behind the lens, and travelling with it, restricted the field of view to the centre of the optical field, and gave a very sharp picture. M. Martens lays stress on the proper adjustment of the axis of rotation of the lens—so that the image of an object does not move on the ground glass—and the apparatus as he designed it is practically identical with present-day instruments employed for the same purpose.

The Copyright Act.

"We congratulate our readers on having at length obtained, by the passing of the Artistic Copyright Act, the means of protecting their works from being pirated by those who prefer robbery to work, or who have neither the wit nor skill to produce anything original of the smallest value. It is full time that a stop should be put to the nefarious practices of those who trade unfairly upon the mental labours of others, and we are rejoiced to find that the long-desired measure of justice to the chief ornaments of the photographic guild has been placed within their reach."

The congratulation and the rebuke are from THE BRITISH JOURNAL OF PHOTOGRAPHY, the former immediately after the passing of the Artistic Copyright Act on July 1, 1862, the latter six months later. A first effect of the Copyright Act was to show up the malpractices of certain photographers who were making a living from the illicit copying and reproduction of paintings and engravings. Alliance of print publishers with reputable photographers was discussed as an aid to taking action against these black sheep of the profession, but a few penalties under the new Act speedily showed the wrong-doers

"We are glad to find that several of our most eminent professional photographers are employing the strong arm of the law through the agency of the Artistic Copyright Act to inflict a just retribution upon those hangers-on to the photographic art who prefer to victimise those who have earned for themselves a name. This they do by the double injury of defrauding such artists of the opportunity of disposing of the fruits of their labour, and, at the same time, by detracting from their reputation by the inferiority of the specimens supplied."

that their practices profited them nothing in the end. Even now, forty-three years after the passing of the Act, its provisions are grossly misunderstood by those who should be versed in the protection which it grants, to them and its bearings on their photographic business. Probably no subject has so consistently been dinned into the ears of readers of the B.J. as the law of artistic copyright, and still the queries which I observe week by week on another page are chiefly on this ever-green and ever-uncomprehended topic.

Daguerre's Diorama.

The possession of an excellent memory is one of the qualifications which the present writer can put forward to justify the part he is taking in the arrangement of these notes, but in anticipation of certain criticism, he would admit that his age is actually less than a hundred, and that a proportion of these retrospective paragraphs owe their existence to a diligent and lifelong study of photographic literature. Thus, in recalling the fact that to-morrow, July 1, exactly eighty-three years will have elapsed since Daguerre first opened his celebrated panorama, the writer would not ask acceptance of that statement on the strength of his "personal presence." But the incident is worth recording, as Daguerre was led to apply himself to photography in the desire to obtain records of natural scenes for his diorama. Two other events of his life took place in the first week in July. In 1833, on July 5, his partner, Nicéphore Niépce, died, and in 1839 (July 2) Daguerre himself was nominated to the Legion of Honour by Louis-Philippe.

HISTORICIS.

RETOUCHING AND COLOURING PRINTS.**I.**

The following practical hints on the spotting and colouring of prints are abstracted from Schultz-Hencke's work, "*Anleitung zur Photographischen Retusche*," as recently issued by Herr Gustav Schmidt, of Berlin, in a fourth and revised edition. The volume does not limit itself to the working up of prints, but in translating from its pages we have collated a number of points and prescriptions on branches of work less dwelt upon by photographic writers than the retouching of the negative.

Working Conditions.

The best position as regards ease of working is to support the print to be retouched on a drawing-board placed at an angle of 45 degrees. To this board it may be fastened by drawing-pins or rested on a shelf made of a thin slat of wood, which may be fastened in the same way. A piece of clean white blotting-paper and ordinary white drawing paper should also be pinned to the board. The former serves to remove excess of moisture or colour from the brush, whilst the latter can be used for testing the colour to see whether it matches that of the print. If a table with a drawer be used, the latter may be pulled out a little way, and the drawing-board placed with its lower edge in the drawer, and, as the back rests against the edge of the table, it will be easy to alter the angle of the board by pushing the drawer in or pulling it out a little.

Brushes and Colours.

Naturally, several brushes will be required, and a soft, wide dusting-brush should be procured. Sable brushes are the best, and from Nos. 1 to 6 will be enough for all purposes; two or three water-colour saucers or tinting tiles should be also provided. The colours required for spotting plain paper prints are Indian ink, Spanish red, vandyke red, vandyke brown, Chinese white, and neutral tint or indigo.

The Indian ink, or, as it really is, Chinese ink, should be carefully selected, nothing but the best being used, as this works up better than the inferior qualities. The colour of this is really a brownish black, and to make it a chocolate or blue black, which are the prevailing tints of plain paper prints, one or the other of these colours must be added. Safflower red can be obtained in the form of sticks, and is used in this form for culinary colouring. It is superior to carmine or crimson lake, as it has less tendency to separate out when mixed with the Indian ink. The best blue is water-colour indigo or neutral tint.

Preparing the Colours.

In mixing the colours, it should not be forgotten that they dry lighter. The correct way to mix them is to damp the tip of one of the fingers, rub it on the colour cake, and then rub the colour off on the saucer, this being repeated with each colour, and then the whole well rubbed together with the finger tip, so that a perfectly homogeneous mixture is obtained. Supposing we wish to use these colours, a little patch of each should be made on the tile or saucer, and then they should be gradually mixed with one another, a little dab being made from time to time on the sheet of paper on the drawing-board to see how near the colour matches that of the print. A brush should be charged with the colour and wiped half dry on the blotting-paper, and then applied to the print with the extreme point of the brush, with a wiping and not a dotting motion, as the latter leaves too much colour on.

If sufficient colour is not applied at first, the same place must not be gone over again until it is dry, otherwise the first coat of colour may be wiped off. Care should be taken not to go beyond the edges of a spot or a darker margin will show, and for large spots it is advisable either to use somewhat similar strokes as when re-

touching with the pencil, or else to fill up the middle and then carefully dot round it. With a very light or very dark portion of the print it is easy to match the tint at once, but for the middle half-tones it is better to apply the colour two or three times.

Albumen and Emulsion Papers.

The utensils for glazed surface prints are the same as for those on plain paper prints, but the colours must be mixed with a vehicle which will dry bright, and an excellent one is albumen and gum. It can be made by beating the white of eggs to a froth, allowing to stand for a day to liquefy, filtering it, and adding to it half its volume of clear 1:4 gum arabic solution.

Special retouching colours are made by Günther Wagner, either in the form of dry sticks, when they must be mixed with the above-described albumen solution, or in liquid form. Winsor and Newton's moist cake colours are also excellent for this work. A bottle of glycerine, two flannel rags, and, of course, clean water, are also required. Instead of the tiles or saucers, a piece of plain glass with a sheet of white paper under it, may be used, or a piece of opal glass.

As the surface of the prints does not readily take the colour, it is advisable to rub it all over with one of the flannel rags dampened with a drop of glycerine, till it appears uniformly matt, and then to use a dry rag till the original glaze has returned.

To mix the colours, the brush should be charged with the albumen solution and with slow strokes passed over the surface of the colour until it is well charged. Then, with gentle pressure, the colour should be transferred to the palette. All the colours should be treated in the same way, and then mixed—with as slow and gentle a movement as possible so as to avoid air bubbles, which are very likely to form.

It is advisable to try the colour on a dark portion of the print, and if it dries with too much glaze it is far better to mix the colour

afresh; if it shows rather less glaze than the original surface of the print, it can be easily brought up by subsequent touching-up with weak gum water.

The foregoing remarks apply to the dry colours mixed with the albumen and gum solution. If the prepared colours are used, the operation is, of course, much easier, as the colours have to be merely transferred to the palette and thence to the print; still, if these colours are thinned down they will dry with less glaze, and therefore it is advisable to thin them down with the albumen-gum solution and not with water.

It is extremely important to have the brush of the exact dryness, and this can be seen by making a short stroke with the point of the brush. If the lower end of the stroke is darker than the top, the brush is too damp, and some of the colour should be removed on the blotting-paper.

With these papers, as with plain paper, a second application of the colour must not be made till the first is dry, otherwise too much colour will be taken up, and it will run towards the edges, and give a light spot with a darker margin.

Naturally, as in negative work, the first thing to do is to remove obvious defects, such as white spots, then we may proceed to the actual working-up of defective prints; but it is impossible to give precise directions, as each print will require individual treatment, and it is only by experience that this can be learnt, but the following hints may be useful.

Flat prints can be improved by deepening the shadows and lightening the high lights. For harsh prints, the reverse holds good. Detail may be put in the hair, the pupils of the eyes may be touched, the nostrils and the lips, as a rule, want deepening in tint. The eyebrows may be strengthened, and the shadows under the brows lightened.

A continuation of Herr Schultz-Hencke's notes, on carbon and bromide prints, must be deferred until next week.

A MODEL PHOTOGRAPHIC INSTALLATION.

THE following description of a modern photographic establishment, intended primarily for reproduction work, is from the "Scientific American," where Mr. C. H. Claudy, a practical photographer and writer, thus describes and illustrates a visit to a notable installation of studios and dark-rooms.

The recently completed photographic department of the Geological Survey at Washington is a model plant in every respect. It represents the height of convenience, the greatest availability of apparatus for the greatest possible amount of use, and the largest possible economy of effort for the required output. This state of affairs exists as the result of most careful planning by the chief of the division, Mr. Norman W. Carkhuff, who has spent the five years during which he has been in charge of the work in tireless endeavour to save time and expense, and increase output.

For Efficient Work.

Everything in this establishment is calculated to increase the efficiency of the individual workman. The apparatus is so arranged that the minimum of time is required for its correct adjustment, and the worker is made comfortable in every way possible, it being the theory that good air, plenty of it, and a cool temperature make for better work than hot, stuffy, and uncomfortable quarters;

fact which everyone who has ever worked in an improperly constructed dark-room will at once appreciate. Nothing has been of too small a nature to receive attention, the smallest details, such as the size of the lens boards, the height of the cameras, etc., having been most carefully thought out. The entire result is a laboratory and photographic gallery which is unique in every way.

A more particular and detailed description follows, which should bring out these points. It must be mentioned, however, that in one respect this workshop, or series of workshops, is not as good as might be desired, and that is in the question of available floor space. The Geological Survey occupies the greater part of a privately-owned business building in Washington, which is too small for the immense interests it contains. Consequently, the photographic department is crowded into a smaller space than it should be.

Camera Facilities.

Entering the department, the visitor passes through the office to a door which can only be opened from the inside, except to those who know how. Passing through this portal, the visitor will find himself in a long and narrow passage, from which open doors, leading to the various rooms. Proceeding along this passage to the left, you enter the gallery, where the first work is done. Here are two large cameras, each taking a plate 28 x 34 inches in size. These cameras slide to and fro on tracks, where they can be instantly locked in position at any point. The fronts of both these cameras are movable up and down, and to and fro, which movements are controlled from the rear by means of revolving rods connected to gearing. This simple idea took considerable working out, but the mechanism was finally simplified to a practical working basis. The result is a saving of several hours a week, otherwise spent by the workmen running around the camera from under the focussing cloth, to adjust the position of the lens. There are twelve lenses in this department, ranging from 20 millimeters to 31 inches in focal length. Except those used only in microscopic photography, every lens in

the place is on its own front board, and every lens will fit every camera, without any adjusting. another simple feature which saves much time. The plate-holders for these cameras are heavy affairs

that room has an opening in its wall, leading into the gallery into which the plate-holder just fits, and where it can be instantly locked to make a light-tight joint. The plate is prepared in the dark-room,

Printing Room, showing drying racks on right and movable hypo trough on sink at left.

naturally, and usually take two men to carry them. Here, however, they are suspended from an overhead trolley line, which runs both lengthwise and transversely, so that they may be carried from dark-

slipped into the plate-holder, which is then closed, and, if desired, the opening can then be closed also with a shutter, keeping the dark-room light-tight when the holder is removed. Stepping into the

Studio, showing adjustment of lenses by fittings operated at the rear of camera.

to camera and back again by one man with the greatest ease. The plate-holder remains hooked to this trolley all the time. Instead of being carried around the passage and into the wet-plate dark-room,

gallery, the workman unlocks the holder, and, simply pushing it on its trolley, guides it to the camera he wishes to use. A slight pull on a handle raises it the inch necessary to fit over the pins, and the

work is done. The opening in the dark-room is at the exact height that the plate-holder is when suspended from the trolley. The amount of work saved by this system amounts to a very large percentage. Besides requiring the services of only one man, it enables him to work with the utmost despatch.

Lighting Arrangements.

The trolley system is also applied to the electric lights used to illuminate the copying-boards. These lamps can be placed in any position anywhere about the copying-boards, and at any height, and all by simply pulling or pushing them into position, where they stay where they are wanted. This arrangement permits the most critical lighting to be made in the minimum of time, a very important consideration, as orders for maps are often sent for immediate filling. The copying-boards are square to the beds of the tracks of the cameras, which beds are cement, laid on the iron structure of the building, so that no vibration caused by walking around or other movement can affect the exposure.

Next to the dark-room, where the wet plates are prepared and developed, comes the intensifying room, then a washing room, then a drying-room, and lastly a glass-cleaning room, all in a line, so that the plate has never to be moved backward, but always progresses forward. Further down the passageway is the printing room. The printing, both from wet-plate negatives and from paper negatives, is done in a large pneumatic printing frame. This is designed expressly for the work, and, so far as the locking and attaching of the

Taking the plate-holder from the dark-room by trolleys.

rubber cloth are concerned, is the only one of its kind extant. Although it requires most careful locking to be effective, Mr. Carkhuff devised a means whereby the locking and unlocking of the back of the frame could be accomplished in one movement of a hand lever, instead of the eight separate movements formerly required. An air-pump exhausts the air from this frame, applying thousands of pounds of atmospheric pressure to the negative and paper, and thus ensuring

an absolutely even contact between them. The back of the frame is counter-balanced, to avoid the needless exertion of strength in raising and lowering it. The frame stands in front of a shutter, behind which is a powerful electric light. This shutter is operated by a foot-lever, and for the average exposure is made to work in about half-second. A specially-prepared developing paper is used, particularly adapted to printing in line, which is the bulk of the work done here.

Fixing and Washing Fixtures.

The print is developed by hand and fixed in a large bath, which can be seen at the end of a big washing sink; this can be swung up out of the way when the latter is wanted for washing the print. The fixing solution collects in a partition at one end of the big tray, and remains there until the tray is lowered, when the solution resumes its former position. When the prints have been washed, they are dried in racks, consisting of spring rollers on which is wound cloth. Through the free end of this cloth, which ends in a turn-over, is thrust a stick. Uprights with serrated edges stand the proper distance from these rollers, and the stick is so fitted as to slip into these serrations. By this device an immense number of prints can be dried at once, and in a very small space, and when no prints are being dried, the cloth stretchers are out of the way. The uprights are movable, also, so that this entire space is available for other things when wanted.

Storing Paper.

A large oak case holds the various sizes and varieties of papers used. Each separate flat cupboard has a false bottom, which can be readily removed. When a fresh consignment of paper is received, this false bottom is taken out, loaded with the paper, and slid back into place. Any one compartment can be opened without exposing the others, and the paper is absolutely safe in them. By using a scheme of this kind, not only is a great saving effected in paper, but in the time required to handle it, and in space formerly occupied by the boxes in which the paper is packed. The ventilation scheme comprises electric fans so placed that they do not merely agitate the air, but actually carry it out at the top and draw fresh air in from out-of-doors.

In the smaller dark-rooms and Velox printing rooms the small work is done. The Geological Survey takes thousands of pictures in the field every year, and these are all developed and printed here. There are a number of small dark-rooms, each a model in its way, and all absolutely clean. The keynote of the whole establishment is absolute cleanliness, and the photographic visitor at once remarks the absence of paper on the floor, junk in the corners, and useless bottles and chemicals on the shelves.

Eleven men are regularly employed in this establishment, and with the great number of labour-saving devices, they easily do the work of triple their number under ordinary circumstances. It is necessary that they should, for the twenty rooms of the laboratory will not stretch, and the work must be done by the force which can be comfortably put in them. Hence every improvement which is made must be either to save space, time, or money.

THE MAWDSLEY FUND.

THE following donation brings the total amount received, in response to our appeal on behalf of Mr. Peter Mawdsley, to £28 12s. 6d. The money thus collected is being applied in the way we have already stated, and will be sufficient for the needs of our friend for some considerable time. We do not, therefore, propose to keep the list open longer:—

"ZIGO" SUMMER-HOLIDAY COMPETITION.

A new competition is announced by Thomas Illingworth, Limited, of Willesden Junction, London, N.W. Cash prizes are offered for the best prints made on "Zigo" self-toning paper from negatives exposed during the months of June, July, August, and September, 1905. The following are the prizes and conditions:—

Class A for small prints (for a set of three "Zigo" prints from same negative not more than 5 inches in length)—First prize, cash £5; second prize, cash £2 10s.; third prize, cash £1.

Class B for large prints (for a set of three "Zigo" prints from same negative, more than 5 inches in length)—First prize, cash £5; second prize, £2 10s.; third prize, cash £1.

Class C for postcards (for the best "Zigo" postcard, one card only for each entry)—Five prizes are offered of £1 each.

Conditions.—1. The competition is open to all amateur photographers who have never taken a first or second prize in any photographic exhibition or competition. The competitor may send any number of prints from different negatives, in one or both classes, but each set must be entered separately. A set of prints is understood to be three prints from one negative, printed on "Zigo" self-toning paper, either glossy or matt, from negatives exposed during the months of June, July, August, and September, 1905. 2. Prints must be mounted, but not framed. 3. Prints only to be sent in—not negatives. 4. All unsuccessful prints will be returned, provided the senders enclose stamps for return postage. 5. The negatives from which the prize winning prints are made to become the property of Thomas Illingworth and Co., Limited. 6. All prints to be sent in not later than October 31, 1905. 7. All prints must be accompanied by the entry form on the fourth page of this circular, and have the name and address of sender on the back of each print, and be addressed to—"Zigo" Competition, Thomas Illingworth and Co., Limited, Willesden Junction, London, N.W. 8. Application forms for the competition will only be supplied through photographic dealers; if your dealer has not them, he can obtain a supply by sending us a postcard. 9. No employee of Thomas Illingworth and Co., Limited, will be allowed to compete.

FORTHCOMING EXHIBITIONS.

July 4 to August 12.—Northern Photographic Exhibition. Secretary, F. G. Issot, 62, Compton Road, Harehills, Leeds.

July 15-25.—Sixth International Salon Association Belge de Photographie, Liège. Secretary, Mr. Servais, 34, Rue du Saint-Esprit, Liège.

August 7.—Andover. Hon. Secretary, W. I. Gradidge, Jubilee House, Andover.

September 8.—International Exhibition at Budapest. Address, Secretary of the Photo-Club, Egyetem-ter 5, Budapest, IV.

September 15-October 21.—Photographic Salon, 5a, Pall Mall East. Hon. Secretary, Reginald Craigie, Camera Club, Charing Cross Road, W.C.

September 21-October 28.—Royal Photographic Society, New Gallery, 121, Regent Street, London, W. Secretary, J. McIntosh, 66, Russell Square, London, W.C.

October 28-November 4.—Sheffield Photographic Society. Joint Hon. Secretaries, J. W. Charlesworth, 1 Joshua Road, Sheffield. and James W. Wright, 62, Vale Road, Sheffield.

November 8-15.—Croydon Camera Club. Hon. Sec., W. H. Rogers, 8, Woodville Road, Thornton Heath.

November 14, 15, 16.—Ipswich Camera Club. Hon. Sec., R. H. Sutton, 37, Henley Road, Ipswich.

November 21-25.—Southampton Camera Club. Hon. Secretary, S. G. Kimber, Oakdene, Highfield, Southampton.

November 25-December 2.—Glasgow Eastern Amateur Photographic Association.

December 1-5.—Hove Camera Club. Hon. Secretary, A. R. Sargeant, 55, The Drive, Hove.

December 12-20.—Southsea Photographic Society. Hon. Secretary, F. J. Lawton, 5, Pembroke Road, Portsmouth.

March 3-10, 1906.—South London Photographic Society. Hon. Sec., H. Creighton Beckett, 44, Edith Road, Peckham, S.E.

March 6-20, 1906.—Glasgow Southern Photographic Association, Hon. secretary, William H. Frame, 28, Bank Street, Hillhead, Glasgow.

FORTHCOMING COMPETITIONS.

July 15.—Warwick. Money prizes for members of photographic societies for pictures taken on Warwick Dry Plates. Warwick Dry Plate Company, Warwick.

September.—Kodak. £400 in prizes for results on Kodak products. Kodak Ltd., 57-61, Clerkenwell Road, London, E.C.

October 1.—Thornton-Pickard. £100 in prizes for photographs taken with Thornton-Pickard cameras or shutters.

October 31.—"Zigo." Cash prizes for prints on "Zigo" self-toning paper. Thos. Illingworth and Co., Limited, Willesden Junction, London, N.W.

THE R.P.S. EXHIBITION.

THE entry form and prospectus of the fiftieth annual exhibition of the Royal Photographic Society has been published. The exhibition will be held at the New Gallery, 121, Regent Street, London, W., from Thursday, September 21, to Saturday, October 28, and will be divided into the following sections:—

1. Pictorial photographs.
2. Scientific and technical photography and its application to processes of reproduction.
3. Photographic apparatus and materials.

The Selecting and Hanging Committee is composed of the following gentlemen:—Messrs. W. R. Bland, Furley Lewis, G. A. Storey, A.R.A., W. T. Greatbatch, J. C. S. Mummery, A.R.I.B.A., and B. Gay Wilkinson, and other members will be appointed later.

The Judges and Selecting Committee in the scientific and technical section are Messrs. T. Bolas, F.I.C., F.C.S., Douglas English, B.A., T. E. Freshwater, F.R.M.S., Chapman Jones, F.I.C., F.C.S., E. Sanger Shepherd, E. J. Wall, and Major-General J. Waterhouse, I.A. This section will comprise examples of work shown for its technical qualities and apparatus used in photographic investigation, e.g., the various processes of colour photography, the photographic reproduction of paintings, drawings, maps and plans, photographs by artificial light, photography as applied to industrial and educational purposes, astronomy, spectroscopy, geology, meteorology, microscopy, medicine, surgery and the Röntgen rays, surveying and engineering, zoology and botany, telephotography, new processes, photography as applied to military purposes, recording instruments, etc., negatives, transparencies, stereoscopic prints and slides, lantern slides, and general work.

This section will also include all exhibits relating to or illustrating any process of photo-mechanical reproduction, viz., photogravure, line and half-tone photo-engraving, photo-lithography, collotype photo-zincography, Woodburytype, polychromatic printing, etc.

In the pictorial section, no exhibitor will be allowed to submit for selection more than six photographs, and these may be by any process.

Photographs already shown at any public exhibition within the London postal district will not be eligible for admission, nor will photographs coloured by hand. No photograph will be eligible for admission unless the exhibitor signs the declaration on the entry form that the work is entirely his own.

There are no medals offered in the pictorial section this year, and there will be no charge for wall space. Medals will be placed at the disposal of the judges in Section 2.

Exhibits sent by carrier must be addressed to the Royal Photographic Society of Great Britain, the New Gallery, 121, Regent Street, W., and must be delivered, carriage paid, on or before Thursday, September 7. Exhibits may be delivered by hand, unpacked, at the New Gallery, on Friday, September 8, between 10 a.m. and 6 p.m., after which time and date no exhibit can be received.

Each photograph in Section 1 must be separately framed, but Foreign and Colonial exhibitors may send photographs unframed. They must, however, be mounted. The Society will provide frames, without charge, for such photographs accepted.

The Central Hall will be reserved for exhibits of apparatus and material (Section 3). Floor space will be let for the erection of stalls. Applications for space should be made by letter not later than Saturday, July 15. Stallholders must provide all tables, stands, counters, showcases, etc. The designs for all structures, decorations, displayed signs, notice boards, etc., must be submitted to the Organising Committee for their approval. Attendants, if necessary, must be provided by the exhibitors. Orders for goods may be taken at the stalls, but no delivery at the exhibition will be allowed. Catalogues, circulars, and price lists may be distributed only from the stalls. Any special lighting required for the stalls must be arranged for by the exhibitor at his own expense. No exhibitor will be permitted to transfer or sub-let any part of the space allotted to him, and no substance of a dangerous nature will be allowed upon the premises. A list or description of the exhibits to be shown in this section must be in the Secretary's possession not later than Wednesday, September 13, if it be desired that particulars shall appear in the catalogue.

Stalls may be erected and exhibits arranged between the hours of 10 a.m. and 6 p.m., from September 11 to September 16, after which time any space allotted but unoccupied will be disposed of as the Committee shall decide.

The charges for space, and all further particulars concerning the exhibition, may be obtained from the Secretary, Mr. J. McIntosh, 66, Russell Square, London, W.C.

Photo-Mechanical Notes.

Newspaper Half-tones.

In reference to our comment some weeks ago, Messrs. W. and G. Baird, of Belfast, write as follows:—

"We have seen a copy of your criticism on a half-tone block of Mr. C. H. Shelley, which appeared in the 'Belfast Evening Telegraph,' and we think it unfair to condemn this process because one particular portrait happened to turn out not quite up to the mark. We have taken great trouble all along with half-tone reproductions in our various newspapers, and think we can claim, without being egotistical, that we have reached high-water mark. We send you a number of papers containing illustrations of this description, including one of yesterday's issue, and we think you will admit that nothing better has appeared in any British newspaper. For various causes the blocks do not always turn out all that could be desired—a bad original, engraving from another half-tone print, unsuitability of paper, and other reasons may be the cause. We think, there-

fore, in justice to us, that you should give us credit for the good work we are constantly turning out, and not base your criticism on an exceptional case. You, as photographers, will undoubtedly be acquainted with many of the difficulties that have to be encountered, and it would be unfair to criticise this work from a photographic standpoint, or from the results obtained by magazine printed on art paper."

Messrs. Baird, we hope, will acquit us of any intention to reflect unfavourably on their work in newspaper half-tones, which is uniformly excellent. They and other photo-engravers supply what newspaper publishers demand, but our note was penned as much as a warning to photographers as a criticism of the present fashion in newspaper illustration. A photographer who supplies a photograph "for reproduction in half-tone" probably anticipates that his work will reappear with a fine ruling of a 133 or 150 line screen. He may overlook the fact that "half-tone" now very largely means the coarse-screen block of the newspaper, and many photographers would object to their work appearing in this form, excellent as the work is considering the circumstances of its production.

"Devils" in Half-tone.

In the current number of the "Zeitschrift für Reproduktionstechnik" attention is called to the occurrence of "devils" in half-tone, quite analogous in appearance to those met with in photogravure, but mainly in the high-lights. When examined with a magnifying glass they showed a deeply etched centre with ragged radiating lines, and they occurred practically in straight lines. It is assumed that this throws considerable light on the phenomenon, and that they are due to extremely fine capillary apertures, which were formed by scratches in rubbing the fish-glue coating, so that the etching fluid penetrated through the scratches more rapidly than through the other parts of the film. The explanation advanced as to the size of these half-tone devils is that by capillary attraction and diffusion a constant stream of fresh ferric chloride passes up and down the little canals. The ferric chloride solution for the fish-glue process is as a rule extremely acid, and the point is whether this acidity can be so far neutralised, as it is in photogravure etching, as to prevent the formation of these defects. But apparently this is not so, as when this point is reached the solution will no longer etch deeply enough.

Trichromatic Work on Ordinary Plates.

Dr. Stenger has been experimenting with ordinary, that is non-colour-sensitive, plates for making the three negatives for trichromatic printing, and some monochrome half-tone illustrations of his results are given as a supplement to the "Zeitschrift für Reproduktionstechnik," together with comparative pulls from a panchromatic plate. A careful comparison of the pulls shows that an ordinary plate can be used for this work, with, of course, enormously increased exposures. Another point incidentally mentioned is that it had generally been considered that the gradation for green, yellow, and orange-red on ordinary plates is not the same as for the blue, but this, by these experiments, has been proved to be wrong. The increase in exposures was considerable, for with a colour-sensitive plate the ratio was 1 : 8 : 25, whilst under precisely the same circumstances the ratio for the ordinary plate was 1 : 750 : 9,000. Dr. Stenger comes to the conclusion that in the most favourable cases a panchromatic (commercial) plate has its green sensitiveness increased about a hundred times and its orange sensitiveness about six hundred times; whilst a bathed plate shows an increase of 180 to 200 for the green, and from 1,500 to 1,700 for the orange. Whilst Dr. Stenger's experiments are interesting, they will hardly induce anyone to use ordinary plates for trichromatic work. It will doubtless be remembered by our readers that Mr. F. E. Ives showed, some ten years ago, some trichromatic transparencies made on ordinary plates.

Patent News.

Process patents—applications and specifications—are treated in Photo-Mechanical Notes."

The following applications for patents were made between June 3 and 17:—

Mounts.—No. 12,273. Photographic mount. Eston Saxe Cheney, 36, Chancery Lane, London.

Vignettes.—No. 12,310. Improvements in copying vignettes for photographic purposes. Richard Hoh and William Hahne, 18, Buckingham Street, Strand, London.

COMPLETE SPECIFICATIONS ACCEPTED.

Specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

Cylindrical Printer.—No. 15,421, 1904. The patent supplements No. 23,014, 1901, and relates to a simplification of the means employed to support the semi-cylindrical table, and to ensure closer contact between the negative and the printing paper. The semi-cylindrical transparent printing table is attached to upright supports by means of hinges in such a manner that when the table is in a horizontal position it rests upon the supports and when in a vertical position it bears against the faces of the supports. B. J. Hall, 39, Victoria Street, Westminster.

Portable Dark-Room.—No. 8,017, 1905. A portable and folding dark-chamber forming, when mounted, a rigid box provided with a viewing hood having red and yellow glasses, two lighting frames, plates of ground glass for regulating the amount of light, a movable mirror enabling the negatives to be examined by transparency and capable of serving as a reflector for illuminating the interior of the dark-chamber, removable shelf bars, a small lower door for the introduction of articles, and two sleeves for the manipulations which the operator has to undertake. Louis Navarre, 65, Grande Rue de la Guillotière, Lyons, France.

Development Process.—No. 17,192, 1904. Paper is coated with a light-sensitive preparation, such as ferric-ammonium citrate, exposed under a negative (printing being controlled by observing the visible image), and a bichromated-gelatine pigment-paper brought into contact with it. By this means a reduction of the bichromate or the like takes place at those parts where, by the action of light, the salt applied to the primary substratum is reduced. At these parts the gelatine contained in the pigment-paper becomes insoluble in hot water. Both papers adhering to each other are placed in hot water, and the pigment-paper is developed in the same manner as in the single transfer process. Thereby the pigment-paper will adhere to the primary paper if the latter is covered, in addition to the sensitive salts, with such substances as are used for manufacturing single transfer-paper, as, for instance, gelatine hardened by alum. Both papers can be again separated from each other a short time after their being brought into contact, whereby the whole pigmented gelatine adheres to its original stratum, but now contains reduction products of the bichromate on the affected parts. The pigment-paper is then brought into contact with the ordinary transfer-paper and the pigment-paper developed. In this case the sensitive paper should not contain any substance which retains the pigmented gelatine, but should contain such a substance as will facilitate the stripping off of the pigmented gelatine, as, for instance, dextrine. Instead of chromated pigmented gelatine-paper, chromated papers prepared with gum or similar substances and colouring matter can be employed, also mixtures of bichromates or chromates with any colouring matter

and gelatine or gum, or similar substances, which are applied in a liquid state to the copy exposed to light. For practical use, the following examples may be indicated:—1. Smooth paper is treated with a solution of—

Gelatine	1 gm.
Alum	0.1 gm.
Citrate of iron and ammonium	2 gms.
Water	20 ccs.

After drying, the paper is exposed to light until the details are just visible in the light parts of the copy. Then the pigment-paper is impregnated with a 5 per cent. solution of bichromate of potassium, the excess of the solution is removed, and the paper is immediately pressed, without being wetted, upon the above copy, so as to avoid air-bubbles. After drying the development is effected in the usual manner, whereby the picture adheres to the originally sensitised paper. 2. Smooth paper is covered with a solution of—

Dextrine	10 gms.
Citrate of iron and ammonium	10 gms.
Water	100 ccs.

After drying, the paper is exposed to light, as indicated in example 1, and then pressed upon the chromated pigment-paper. After about one minute, the two papers are separated from each other, the pigment-paper is quickly rinsed with cold water and then pressed upon dry ordinary transfer-paper, or any other correspondingly prepared substratum, thereby avoiding air-bubbles. After completely drying, the development is effected in the usual manner. 3. A heliographic printing plate is preliminarily prepared in the usual manner, covered with gelatine and dried. Then the plate is chromated in a 5 per cent. solution of bichromate of potassium. The surplus of the solution is removed and a paper, prepared as indicated in example 2, and exposed to light, is then pressed upon the plate. After about one minute, the paper is drawn off, and the plates are dried and washed. Dr. Ludwig Strasser, 34, Kantstrasse, Charlottenburg, Berlin.

New Books.

"Anleitung zur Photographischen Retusche und zum Uebermalen von Photographien." By D. Schultz-Hencke. Berlin: Gustav Schmidt. M 2.50.

Few books in any language treat so fully of the various retouching arts applicable to photography as this German volume, now in its fourth edition. It devotes itself less to the methods of negative retouching than to the different modes of working up prints. In this latter task, it considers the different requirements of silver, platinum, carbon, and other prints in the matter of making colours and crayons "take" to the surface, and we can give no better notion of the quality of its instruction than by collecting, as we do on another page, certain of its precepts and formulae.

"The Hand Camera and What to Do with It." By W. L. F. Wastell and R. Child Bayley. Published by Illiffe and Sons, Limited, Price 1s.

This book, which is intended to take the place of the work on "Hand Camera Photography" by W. D. Welford, deals fully and comprehensively with every type of the modern hand camera and methods of working, and gives full instructions for all those forms of photography in which the hand camera can be employed. Lenses, shutters, movements, and fittings come in for ample consideration,

and the exposure from the point of view of the plate and of the subject is also dealt with. Work with films, development, printing, enlarging, and sundry other matters likely to be of great service to the user of this popular type of photographic outfit are discussed in a practical manner, and working formulæ are given whenever possible. The book, which is a bulky little volume, is admirably illustrated with good half-tone reproductions of hand-camera photographs by Mr. R. Child Bayley.

"HORSHAM AND ST. LEONARD'S FOREST," the delightful part of the Weald of Sussex so quickly reached by Londoners, is the subject of Vol. 38 of the *Homeland Handbooks* (The Homeland Association, Limited, 22, Bride Lane, Fleet Street, London, E.C., 1s.). Guided by it, a great variety of beautiful country can be visited, and we commend it particularly to the Metropolitan photographer seeking fresh fields for week-end rambles with his camera.

WHERE to go for a holiday? Those in the throes of indecision should be glad to obtain the "Seaside and Inland A B C Holiday Guide," issued by the Wentworth Publishing Company, Clun House, Surrey Street, Strand, London, W.C., price 1s., which says what there is to say of the salient features of holiday resorts with commendable brevity.

New Materials.

"A new Negative Draining Rack." Made by Houghtons, Limited, 88 and 89, High Holborn, W.C.

This new draining rack is constructed on practical lines in a sensible manner. It is extremely rigid, and when it is opened for use the legs extend to the right distance and cannot be forced further apart. These legs are of metal, and the rack itself is of cherry wood with grooves cut to take twelve negatives, and they are so shaped that the water which drains from the surface of the negatives will

not accumulate at the bottom edges of the plate. The grooves are placed $\frac{1}{2}$ in. apart, thus allowing more ventilation than usual. The drying is therefore accomplished in a much shorter time than is usually the case with draining racks in which the grooves are close together. No metal comes into contact with the negatives, but we think a slight improvement might be effected by the addition of a small strip of metal fastened to the back of each grooved piece of wood to prevent warping. The rack is well made, and is cheap at 10d.

"Seltona-Platino" Printing-out Paper. Sold by the Leto Photo Materials Company, Ltd., Rangoon Street, London, E.C.

This self-toning collodion paper, issued with a matt surface only, lends itself admirably to either of three methods of treatment, viz.: (1) fixation simply, giving sepia tones; (2) fixation after immersion in a salt bath—blue and purple tones; and (3) toning in a platinum bath for warm black tones. Printing must be decidedly deep, as the prints lose a good deal in

depth in the after-operations, but with this precaution the paper calls for no especial comment as regards manipulation, and yields a variety of tones, according to the method adopted, a feature which must recommend it to the professional worker. It is issued in all the usual sizes, packets, boxes, and postcards, at a price based on 17 per dozen 24 by 20 sheets.

RECEIVED.—The "Marion-Iso" Plate (Marion and Co., Ltd.). Herold's Emulsion Gelatine (Otto Rosenstiel). These articles will be noticed in due course.

WHITE'S Patent Multiple Postcard is the latest novelty in picture postcards from the Photochrome Company, of Cheapside. The postcard takes the form of a thin card wallet, open on one side to permit the viewing of a picture card within. If this card is pulled out at an opening left at one end, another view is disclosed, and by pulling still further a series of smaller views, separately mounted on small cards, appear in rapid succession, each turning over and showing yet another picture on its back, like the leaves of a miniature book. Each complete card is, therefore, a small view album in itself, and, as a pleasing novelty, should command a ready sale.

News and Notes.

We are sorry to see from the current "St. Veronica" that Editor Dr. George Ewing has been too unwell to take any part in its production. We miss the forcible comments on men and matters in India, and selfishly wish our *confrère* a speedy recovery.

THE programme of the examinations of the City and Guilds of London Institute is now published by John Murray, Albemarle Street, and contains the syllabuses for photography and photo-mechanical processes. The subjects on which questions will be asked in the examinations in May of next year differ very little from those of previous years. The examiners in photography are:—Sir W. Abney, Mr. G. Watmough Webster, and Mr. J. D. Geddes.

THE Croydon Camera Club have fixed the date of their annual exhibition for November 8 to 15 next, to be held in the Horniman Hall, North End, Croydon. Six open classes have been arranged, including a special class for lady exhibitors only. The exhibition secretary is W. H. Rogers, 88, Woodville Road, Thornton Heath, who will be pleased to forward entry forms and answer any inquiries.

"THE Urban Cinematograph Films." A comprehensive illustrated price-list of Urban films has been sent us by the Charles Urban Trading Company, Limited, of 48, Rupert Street, London, and as an example of descriptive advertisement in catalogue form would be hard to beat. The quality of the Urban films is amply demonstrated nightly at the Alhambra Music Hall, and the enterprise of the company is well indicated by the range of subjects touched upon and the promptness with which news items are portrayed and displayed on the screen, which can, under the circumstances, almost be regarded as a sort of illustrated supplement to the morning papers, the pictures being, moreover, reproduced with all the additional charm of motion. The company's registered trade mark is "Urbanora"—we put the world before you"; and every body interested in cinematography or the display of animated pictures, should apply for a copy of this bulky catalogue without delay.

"NIHILISTS IN RUSSIA" is one dramatic film just listed by Messrs Gaumont and Co., Cecil Court, Charing Cross Road, London, W.C.

WOMEN'S Studios in New Zealand.—Operating in the studio with the camera was for a long time reserved for men only, who have

also had the monopoly of running the show, but at Napier and Wellington ladies have for some time been proprietors of the studio (according to the "New Zealand Photographer"). At Nelson, Mrs. Brusewitz ably represents her husband as operator in the studio, and at Christchurch Miss Beattie Bond advertises her business as the People's Studio, and herself as the Lady Photographer.

DEATH of Mr. T. C. Hepworth.—Our intimation last week of the death of Mr. T. C. Hepworth was received as we went to press, and we must now more adequately express our regrets at the demise of a man whose name, at any rate, must have been familiar to all classes of the photographic community. Mr. Hepworth was a journalist and a lecturer as much as a photographer. In fact, his popularity on the lecture platform was the most distinguishing feature of his professional career. In the Midlands and the North of England, where the instruction lecture commands a keener audience than it does in the South, his lantern discourses on scientific topics

The late T. C. Hepworth. Died June 14, 1905.

were among the fixtures of the season, for he possessed the rare gift of making an intricate subject clear and attractive to the non-scientific hearer. Mr. Hepworth was associated with photography in a number of ways. For some years he was proprietor and editor of "The Photographic News," and a good many contributions to the photographic Press of recent years came from his anonymous pen.

MESSRS. GOLDSMITH, of Manchester, held their annual picnic on Saturday last in the Greenfield district, where the party enjoyed rambles among the lovely glens and on the Yorkshire hills. The after-dinner speeches, although brief, proved the good feeling which exists between employers and employed, and "good luck to the firm" was the universal theme.

R.P.S. SPECIAL MEETING.—The special meeting called for July, to receive nominations and to elect members, will be held on Tuesday, July 11, at 66, Russell Square, W.C.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

July.	Name of Society.	Subject.
1.....	Bowes Park and Dis. Ph. Soc....	Outing. River Thames.
1.....	Glasgow Southern Ph. Assn....	Outing to Garelochhead.

6.....	Röntgen Society	Annual Meeting.
6.....	Hull Photographic Society ...	General Meeting, Society's Rooms.

ROYAL PHOTOGRAPHIC SOCIETY.

MEETING Tuesday, June 27. J. C. S. Mummery in the chair. Mr. F. C. Tilney read a paper, entitled "The Romantic in Landscape." The lecture did not in any way deal with photography or photographic methods, although the occasion was announced as a technical meeting. The lecturer dealt in a thoughtful manner with the questions arising out of a critical inspection of some of the works of the best landscape painters of the past 150 years, and drew the general conclusion that these works of art were more imbued with the air of mysticism and romance than could be achieved by modern photography. He prefaced his remarks by defining "romantic" as pertaining to romance, meaning thereby any fictitious and wonderful tale, anything fanciful or marvellous, suggestive of mystery and adventure in the style of the Middle Ages as opposed to the classical antique. Therefore, wild and picturesque scenery, characterised by strangeness and mystery, would appeal to the imagination as romantic. He particularly instanced the pictures by Claude as arousing and stirring the sentiments and passions by their suggestion of the unknown. The romantic in art was subjective, and this suggestion of mystery in many of the landscapes referred to tended to arouse the romantic feelings of the beholder. The play of light was always an important factor in romantic scenery, while dark shadows and murky spaces, with their air of mystery, always aroused romanticism inborn in all of us. The marvellous and uncanny always fascinated us, and dark woods, caverns, and deep shadows in landscapes took hold of the imagination. Mr. Tilney stated that all broad scenic effects were borrowed from romantic art, of which scene painting was a type. Scenic effects were not to be confounded with stagey effects or bathos would inevitably result, and the best and most striking results that touched our imagination were obtained from subjects that were not too crowded in treatment, but in which simplicity and dignity were predominant. Such broad, simple methods, free from distraction, especially if a certain indication of the unknown and suggestions of mysterious shadows were included, could be justly termed the romantic in landscape. The lecturer showed a number of slides made from well-known pictures by Claude, Richard Wilson, J. T. Hardy, David Roberts, T. Allen, Turner, and Gainsborough, and pointed out their claims to be considered romantic. He compared them and also showed several ordinary photographic snapshots, from which he drew conclusions not altogether favourable to photography when compared with the finished masterpieces of the painters. In reply to members who took part in the discussion that followed, Mr. Tilney said he did not

think the emotions of pictorial art were altogether debarred from photography, and although a photographer might be capable of producing pictures, he did not think that an art training could be obtained at art schools. The germ of the art instinct was born in a man, and the function of the art school was little beyond teaching how to sharpen pencils and the rules of composition, etc. The germ of the art instinct was fructified by contact with artists and others whose opinions were worth following. In conclusion, he impressed upon photographers that romance was not in the photograph, but should be in the photographer to enable him to impress his individuality on his work.

THE BLAYDON AND DISTRICT CAMERA CLUB.—Mr. J. Parker, 7, Evelyn Terrace, Blaydon-on-Tyne, has been appointed Secretary of this Society.

SOUTHAMPTON CAMERA CLUB.—At a meeting of this club at the Philharmonic Hall, Southampton, on Monday of last week, a lecture on the preparation and working of plain salted printing papers was given by Mr. G. T. Vivian, and a demonstration of gum-bichromate printing was given by Mr. W. Miles.

HULL PHOTOGRAPHIC SOCIETY.—The annual picnic of this society took place last week to Burton Bushes, Beverley. The outing was a pronounced success.

SOUTH NORWOOD PHOTOGRAPHIC SOCIETY.—At a meeting of this society, held on Thursday of last week, Mr. H. Clark gave a demonstration on the working of the reflex hand camera.

The club has now taken larger and more convenient premises at 251, Selhurst Road, South Norwood, and are moving into them this week. It is hoped that now they have secured larger rooms there will be a considerable increase of membership from the ranks of amateur photographers in South Norwood and district.

SUTTON PHOTOGRAPHIC CLUB.—The first outing of the season, arranged by the Chairman, Mr. Hector Maclean, took place on Saturday last to Warnham, and an excellent day was spent in the grounds and mansion of Mr. C. S. Lucas, the owner of Warnham Court.

LOUGHBOROUGH PHOTOGRAPHIC SOCIETY.—The members of this society spent a very pleasant half-day in the Matlock district on Saturday last. Matlock Bridge, Darley Dale, the old church of St. Helens, Matlock Bath, and the High Tor were the chief points of interest photographed.

LEEDS PHOTOGRAPHIC SOCIETY.—The members of this society visited York on Saturday last on the occasion of their annual excursion. The Minster, St Mary's Abbey, the Museum, and other places of interest were inspected.

The pleasant feeling existing between the Herefordshire, Gloucestershire, and Shropshire Photographic Societies was shown on Thursday of last week, when the three organisations held a joint field-day in the neighborhood of Ludlow. The outing proved a great success in every way, and the Herefordshire Society will pay a return visit to the Gloucestershire Society on July 20, when the rendezvous will be Evesham and Broadway.

PHOTOGRAPHY in a New Role.—The Normanton Education Sub-Committee have instructed their head teachers not to allow the school work to be interfered with by travellers, photographers, and "all other nuisances."

"Zigo" Demonstration.—A series of special demonstrations of printing on "Zigo" paper has been arranged by Thomas Illingworth and Co., Limited, at Harrods, Limited, Brompton Road, London, S.W. These demonstrations are given free in the photographic department every day from 10 a.m. to 5 p.m.

Commercial & Legal Intelligence

FORGERIES by Photography.—Unusual features characterise the case of Frederick Ellis Blackburn, a clerk, who was committed for trial from the Mansion House last week on a charge of forging a cheque for £200. There are also alleged to have been other forgeries. The prisoner was in the employ of Mr. Rudin, a cigar merchant, of St. Dunstan's Hill, and was left in charge of the office when Mr. Rudin went for a short holiday last July. He stated that "During Mr. Rudin's absence a man named Woolf, of New York, suggested that Mr. Rudin's signature should be photographed and a process block made from the signature, so as to enable him to stamp direct on to a cheque after the block was made. He stamped a few cheques, and filled in the amount. Then we proceeded to Lloyd's Bank, where the money was obtained. The greater part of the money he kept himself, and either proceeded direct to New York or Paris."

A CASE OF COPYRIGHT INFRINGEMENT.—Dunning v. Grimble.—In the Chancery Division, on Thursday, Mr. Justice Joyce had before him an action by which the plaintiff, a photographer, of Usk, sought an injunction to restrain the defendant, the author of a work on the salmon and sea trout rivers of England and Wales, and his publishers from infringing six photographs taken by plaintiff. His Lordship, after the case had been opened, suggested a compromise, and ultimately it was arranged that there should be judgment for the plaintiff for £25 and no order as to costs and the plaintiff gave permission to the defendant to sell the remaining numbers of the work.

Correspondence.

- * * Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.
- * * We do not undertake responsibility for the opinions expressed by our correspondents.

THE NON-RETURN OF SPECIMENS.

To the Editors.

Gentlemen,—I am sorry to trouble you, but this is the second time I have had cause to complain of the non-return of specimens I have sent in answer to advertisements printed in your **BRITISH JOURNAL OF PHOTOGRAPHY**. In both cases particulars had to be sent to your office.

The enclosed advertisement is the second that has failed to return specimens, amongst which was a cabinet photograph of myself—and I did send the necessary stamps for their return.

Can you help me? For the loss of two sets of specimens means a great deal to me. I am trying to get a situation, and, as you know, it is impossible to get one without specimens.

I think such conduct on the part of advertisers is most ungentlemanly. It strikes me that some people advertise under cover of your address for the express purpose of getting other people's specimens for their own use, and in such case as mine (if only in justice to yourselves) you would do quite right in disclosing name and address of offenders.—Yours truly,

R. R.

[The above is one of three letters making the same complaint of different advertisers, and we are sorry to find that it should be necessary for us to refer in strong terms to the matter. Our view of the question is simple enough:—The applicant who, in sending specimens to an advertiser, does not value them sufficiently to en-

se postage for their return, need not be surprised if he or she sees them again. On the other hand, the advertiser who mails specimens when their return is prepaid, lacks the most primitive instincts of a gentleman, and deserves to be treated accordingly. In the cases of our three complainants we have taken steps which we hope has brought about the return of their property, and we must caution those who are found to be holding what does not belong to them that their conduct is a grave abuse of our advertisement columns, and one which we shall spare no pains to prevent. Fortunately, such instances are not frequent, a fact which renders all the easier our task of keeping an eye on those whose past record in such matters is not clean.—Eds., B.J.P.]

BUSINESS ASPECT OF THE COPYRIGHT QUESTION.

To the Editors.

Gentlemen,—Will you allow me to ask one more question on the subject about which I wrote you last week?

If the photographer sells his copyright with the proofs or portraits to his customers, how is it that the artist who paints a portrait for a customer retains the copyright, and is able to sell it either to the customer or to anyone else? The Act deals with paintings, drawings, and photographs, and I fail to see why Jones, R.A., should be paid £500 for painting a portrait and be able to get another £100 for the copyright, while Robinson, photographer, should have content with 1s. 8d. for the proofs supplied, representing many hours' work, when operator, retoucher, and printer are considered, and he no copyright in his work at all.

When the Copyright Act says that the "vendee" (the sitter) is entitled to any copyright unless at or before the time of sale (pay for the proofs or photographs, I take it) the seller signs an agreement giving the vendee the copyright.

I do not see anything in the Copyright Act about the copyright going to his only when he invites the sitter to sit.

The question is not what the custom is, but what power does the Copyright Act give the photographer.

As to the price to be charged for proofs, I doubt if any photographers fix this on their price lists; our prices are for dozens or half-dozens, as the case may be.—Yours obediently,

F. M. SUTCLIFFE.

Whitby, June 24, 1905.

The points raised by our correspondent were covered in our notes last week. Our correspondent asks: "If the photographer sells copyright with the proofs, etc.?" Now how can he sell what does not belong to him. The customer pays (or can be made to pay) for his portrait, and the copyright in it is vested in him. Our correspondent must know that if an artist paints a portrait for a customer the painter has no copyright in it, unless by special agreement in writing with the customer? Evidently our correspondent has not read the Copyright Act carefully, for the very first section of it makes the matter quite clear. In the letter it is contended that there is something in the Act about the copyright being the photographer's when he invites the sitter to sit. But in this case the photographer is not paid a "good and valuable consideration" for taking the portrait, hence the copyright in it is vested in him.—Eds., B.J.P.]

TERRIBLE Accident.—Edmund E. Hill, an Englishman residing in Galway, and trading as a photographer, met with a terrible accident on Sunday while motor-cycling near Galway. Losing control of his machine going down a hill he dashed into a wall and was thrown over fully fifteen feet on the opposite side. He received terrible injuries, his neck being dislocated, and he now lies in a critical condition.

Answers to Correspondents.

- **All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C. Inattention to this ensures delay.*
- **Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*
- **Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.*
- **For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.*

PHOTOGRAPHS REGISTERED:—

- F. G. Jones, Earlscliff, Oxtou, Cheshire. Photograph entitled, "Evening on Killarney." Photograph entitled, "Watergate and Ferry, Norwich." Photograph entitled, "In the Black Valley, Kerry."
- B. T. Cornforth, 5, Rock Street, Hr. Broughton, Manchester. Photograph of the Canal Bridge, Moncton.
- C. C. Whyte, 4, Ardross Street, Inverness. Photograph, 15 in. by 12 in., Group of Journalists with Dr. Carnegie at Skibo Castle, Sutherlandshire.
- Isaac Perkoff, 186, Commercial Road, London, E. Photograph of Mayor, Mayoress of Stepney, and Members of the Stepney Borough Council. Photograph of Mayor and Aldermen of Stepney.
- J. Webster, 25, The Pavement, Clapham Common, London, S.W. Two Photographs of the Rev. D. McEwan, D.D. Photograph of the Rev. E. S. Wood.
- C. W. Eastoe, Castle Hill House, Caistor, Lincolnshire. Photograph of the Mausoleum at Limber, Brooklands, Lincolnshire. Photograph of the "Stone Sack" at Fonaby, Caistor.
- J. Morgan, 7 and 9, Lammas Street, Carmarthen. Photograph of Schreyer, the American Aerial Cyclist and High Diver, during Performance at Carmarthen.
- J. H. Kinsman, Lawson Villa, Ashley Road, Upper Parkstone, Dorset. Photograph with Schooner in left foreground; the Description in right foreground.
- W. Hollick, 78, Wellington Street, Woolwich. Photograph of Mr. J. Dick.
- Mrs. G. Bainsmith, St. Ia Studio, St. Ives, Cornwall. Photograph of Miss J. Ellis. Photograph of Miss M. Keegan.

BOB WOOD.—J. Epstein and Co., 33, Broad Street, Bristol; O. Sichel and Co., 52, Bunhill Row, London, E.C.; and Gothard and Co., Plumstead Road, Woolwich, S.E.

WM. GORE.—As soon as you register you can prevent further infringement.

SENSITISED FABRIC.—Could you kindly assist me with a recipe for a sensitising fluid for silk, etc.? I believe I have come across one in an old edition of the B. J.—D. S. BAKER.

After scalding the silk, size and salt it with a solution of arrowroot and common salt, enough of the former to make the fabric somewhat stiff when dry, and of the latter to make the mixture taste salt. Sensitise by immersion in silver nitrate 150 gr., water 3oz., made faintly acid with nitric acid. Dry in front of the fire. The fabric is printed very deeply, washed in two or three changes of water, and toned in an ordinary acetate bath, being finally fixed in hypo.

CLEANING DISHES.—Will you kindly advise me the best means for cleaning granite hypo. fixing dishes, which has left a thick black deposit of hypo. on bottom and partly on sides? I have never noticed this in fixing dishes before. What would be the cause, fresh hypo. being made once a week?—C. F. WYNNE.

We presume you mean "granitine" dishes. Spirits of salts mixed with an equal volume of water will cleanse them thoroughly. The only cause we can suggest is that acid has found its way into the fixing bath, say from platinum toning solutions.

HOUSE DUTY.—The premises in which I carry on my business are in the centre of the town; some year or two ago I moved out of

them to the suburbs. At the time I did not know that I need not pay the tax for the house, as no one occupied it at night. In fact, I have only heard this recently, and should be glad to know if I can get back the money I have paid.—UNDERSTOOD.

An exemption from this duty is granted to shops, warehouses, and offices which are used solely in trade or professions, no person sleeping thereon. If the premises should in error be assessed, the occupier should appeal against the assessment and get it discharged. If he fails to do this, and actually pays the duty, his only remedy is to send the receipt to "The Secretary, Inland Revenue, Somerset House, London, W.C.," who will cause inquiry to be made, and if all turns out right they will refund the duty.

A. DUBLANGE (Le Fleux).—If you address Mr. Bellamy, care of Literary and Scientific Society, Reading, the letter will doubtless reach him.

W. H. (Woolwich).—It is not necessary.

G. WOOD.—There is no journal in France of the character of the B. J. The best for your purpose is the "Photo Revue," 118, Rue d'Assas, Paris.

COPYRIGHT.—Will you kindly answer the following question?—One of my photographs, which was not copyright but which I have since registered, was reproduced in the first issue of — without my knowledge or consent. I drew the editor's attention to the same, and asked a small fee for right to reproduce. I received a very courteous reply to the effect that the photograph was supplied by the party who bought the same from me, and that I had no claim against them. Now that my photograph is registered, can I legally stop the sale of further copies until my claim is paid?—J. P. MILNES.

Yes, we should say you can, by taking action against the publishers of the work. Your best way will be to consult a solicitor acquainted with copyright law. Possibly a firm letter to the publishers threatening legal proceedings will bring you your fee.

MASKED BORDERS.—Will you kindly inform me the best way to print "Cosway Borders" in bromides? How do you get perfect register in the double printing?—C. POWELL.

The simplest way is to fix on the mask of the portrait negative, say at the top left-hand corner, a couple of strips of thin cardboard at exact right angles to each other, and similar strips in corresponding positions on the border negative. Then, if the bromide paper be placed close against these strips in each printing, accurate registration will be secured.

COPYRIGHT.—Will you give me your opinion of the following?—I hold the copyright of a postcard which I have published. I supply a wholesale dealer with a quantity of same. He has some of them hand coloured, and offers them for sale. Is he infringing my copyright by so doing, and can I prevent him colouring them?—J. DONALDSON EDWARD.

The dealer is in no way infringing your copyright, as he purchases the pictures from you. We do not see how you can prevent him from colouring them—he has the right to do as he likes with his own.

THE AMATEUR QUESTION.—A. exhibits in a local exhibition; the rules say professionals are not eligible as competitors. A. styles himself an amateur, and, although he does not do it for his livelihood, he often sells his photographic work at a good profit. Can he, under these circumstances, be eligible to compete as an amateur?—OLD SUBSCRIBER.

It is not easy for us to say. We should not take the view

that occasional sales of photographs made a man a professional but if his photographic business forms an appreciable portion of his income he might reasonably be held ineligible.

STUDIO LENS.—I am desirous of acquiring a portrait lens for use in a 16-ft. studio. I have been using a 13 in. focus rectilinear lens, but find it not fast enough for dull weather. Please advise which would be suitable, and say the best size for cabinet work.—R. N. CLIFFORD.

To take a full-length cabinet portrait in so short a studio you will require a lens of about 9 in. focus. That will require from 12 ft. to 13 ft. between the sitter and the camera. We doubt if you will get a cheap Petzval portrait lens of that focus that will cover, well, the cabinet size picture. A lens of longer focus will do for three-quarter lengths and bust pictures, and, of course, will cover the plate better than will one of short focus. The lenses named in your list are all good value for the money.

PUZZLED.—1. In all probability the peculiar markings are due either to contact of the prints with metal—which may frequently happen if an enamelled metal print washer is used and some of the enamel chipped off—or else to an acid mountant. 2. Your trouble arises from the hot weather. Soak your prints after washing in a 5 per cent. solution of formaline for five minutes, then rinse well, cleaning the glass well with methylated spirit and ammonia, and polish clean.

SENSITISING POSTCARDS.—Will you please give me the formula for sensitising postcards for P.O.P., as I cannot get a copy of this year's "Almanac."—J. HARRIS.

The following is a good formula:—Nelson's No. 1 gelatine, 87 grains; ammonium chloride, 18 grains; Coignet's gelatine, 87 grains; Rochelle salts, 50 grains; silver nitrate, 75 grains; alcohol, $\frac{1}{2}$ oz.; water, 5 oz. Heat to 100 deg. F., and allow to remain at this temperature for ten minutes.

THE Photographic Convention.—The final arrangements for the Convention at Dublin, which opens on Monday, July 10, are now in an advanced state, and there is every prospect of the pleasurable week of 1894 being re-experienced. A party will leave London for Dublin on Thursday next, July 6, and those who travel via Holyhead might well form one of the party, if it is still possible to provide additional travelling accommodation. Mr. F. A. Bridge has charge of the arrangements, and a line to him at East Lodge, Dalston Lane, N.E., will bring the information.

R.P.S. ENTRY FORMS.—The secretary of the Royal Photographic Society has sent us a supply of entry forms for the forthcoming exhibition at the New Gallery. We shall be pleased to forward a copy to any of our readers on application.

**** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

EX CATHEDRA.

Comprehensive photographic apparatus.
The "Standard," in its "Parliamentary Notes" one day last week, says an order has been circulated to commanding officers of the Navy forbidding purchases for the Service outside the regulation stores, without official permission. Charge was made in respect of photographic printing machinery ordered by the officer commanding a King's ship. The price paid was £47, the sale value being £6. The discrepancy was discovered through the medium of the Public Accounts Committee, and hence the new order issued. This body has recently been charged with overlooking matters where large sums have been expended. But it is evident that they are pretty vigilant for small amounts. It would be interesting to know of the "photographic printing machinery" consisted the price of which was six pounds.

Exposure Portrait negatives.
We frequently see portraits in which the shadows of the face are nearly, if not quite, as dark as the shadows in the draperies. It is a somewhat common mistake to suppose that if the shadows show detail the plate is sufficiently exposed, quite ignoring the fact that under-exposure part of the curve of the plate has been used, and that the detail, though present, is not sufficiently strong to print. The effect is that the shadows of the face are heavy and black and lacking the luminosity which flesh should always possess. If the plate used has little latitude, it will usually be found that by the time the shadows are fully exposed the tipped high-lights will be lost for printing purposes, and will need to be strengthened by the retoucher. This, however, is more easily done than a general lightening of the shadows. The latter plan, of course, is to use a plate with latitude, so that both shadow detail and good modelling may be

secured without flattening of the extreme high-lights. Even in the strongest effects of lighting, such as Rembrandt portraits, the shadows of flesh should be much more luminous than shadows in dark clothes, and if the blinds or headscreens cannot be manipulated to produce the effect, it may be necessary to use a large grey reflecting screen at some distance from the sitter, taking care to avoid false illumination. The cases where shadows are heavy through under-exposure, necessitated by exigencies of the weather or a restless sitter, are amongst the unavoidable which so often crop up in photographic work.

Use of the Pinhole.

Notwithstanding the tendency to, and the undoubted advantage of, specialisation in professional photography, there are many places where the worker must take anything in the nature of a commission which comes his way. Buildings in narrow thoroughfares, or where the space in front is restricted in proportion to the size of the structure, are often required to be photographed, and in some cases the work could be done had the worker one of the extremely wide-angle lenses now obtainable in his possession. Instances have come under our notice, however, where no lens would serve, and we have known successful photographs made under such conditions by the aid of a pinhole. Probably the simplest way of making a pinhole is to take a bit of thin sheet copper and grind one spot thinner with flour emery and oil and the tip of the finger, finally working a needle of the proper size through the thinned place in the copper. By reversing the camera and looking through the pinhole, or, better, a larger hole in the same position, the exact distance from pinhole to focussing screen may be ascertained, the camera really acting as a direct vision finder. It may then be swung round exactly 180 degrees and the plate inserted and the exposure made. With a slow landscape plate the exposure will be long enough to prevent any sign of moving figures, and if the size of the pinhole is correct, the definition should be almost as good as with any of the non-anastigmatic lenses. Prints, of course, would be made by a matt surface process.

A Tax on Itinerant Photographers.

Certain professional photographers in Montreal, so we read in the "Star" newspaper of that city, are complaining of the competition with the men who go from house to house obtaining orders for photographs. Their protest is a petition to the municipal authorities asking that the itinerant photographer shall be taxed. The regular photographer, they point out, has to pay the taxes on his establishment as well as a business tax, charges which the photographic canvasser escapes. The proposition of a tax was made to the Finance Committee and referred by them to the Law and Licence Departments. It is diffi-

cult to see, however, how the itinerant photographer can be effectually dealt with by legislative methods, because as soon as he is spotted by the authorities he can change his habitat to another district.

Grandmotherly Society Management.

We read in the organ of a photographic society the following tremendous piece of intelligence:—"The dark-room lamp has been overhauled and repaired by Mr. —. The glasses in the sides are ruby only, and in the front, ruby in front of orange. Bromide workers need only slide up and out the front glass to obtain an orange light. It is unnecessary to turn the lamp round to light it, as the small slide at the back can be reached in position without difficulty. It will be found much more comfortable if members, when at work in the dark-room, do not turn the light up to its fullest and it will also allow the lamp glasses to remain clean much longer." Our congratulations are tinged with wonder as to what sort of society-members these must be who need to be told how to light the official dark-room lamp. It is to be hoped for the credit of the society that the paragraph is the work of some fussy individual, and is resented by the members. If this kind of thing is going to be done why not more thoroughly:—The dark-room door can be conveniently opened by a rotary movement of the knob, followed by a perpendicular thrust. It is well to close the door before developing plates.

Mil and Centimil.

The new designations of the thousandth, ten-thousandth, and hundred-thousandth part of a litre proposed some time ago by the General Medical Council and the Pharmaceutical Society have now been approved by the Comité International des Poids et Mesures, for adoption in England for pharmaceutical purposes. The abbreviations are:—

Mil	Millilitre.	Approx. cubic centimetre.
Decimil	$\frac{1}{10}$ "	" 1 c.c.
Centimil	$\frac{1}{100}$ "	" 0.1 c.c.

For practical purposes "mil" may be read as "cubic centimetre," as the difference between the two is extremely small. The new words may, however, be noted, as they are likely to be employed in pharmaceutical literature before very long. It is understood that the next British Pharmacopœia will use them in formulæ for fluid preparations.

Photographers' Grievances.

In a leading article a fortnight ago we referred to a photographer's complaint of his sitters having their portraits taken by him and then getting them reproduced by some cheap copying firm. This week there is a letter in the correspondence column on the same subject. The writer quotes our former article that: "He (the photographer) has not so much to complain of, seeing that he has been paid for what he has done," and adds that it "is but poor comfort." That is perfectly true; it is but small comfort, and we regret that we cannot offer better. But business—whether photographic or other—must be looked at from a business, and not a sentimental, point of view. Facts as they exist have to be faced. Our correspondent, in his letter, says it has been the custom to spread the cost of the first copies over the whole order, or prospective order—say half a dozen or a dozen—and if smaller numbers are taken, it is with the hope that the balance will be adjusted by further orders. As a rule it is, but in exceptional cases it is not. The question is one of risk. Grocers sometimes sell sugar at cost price—even less—in the hope of the purchasers buying tea or other things upon which the grocer would

profit. But often the purchaser goes elsewhere for his tea, and the grocer has no ground for complaint, as he has been paid his price for the sugar. Photographers, we fear, are too apt to look at matters solely from their own point of view, quite ignoring that of their customers. If the latter pay for their portraits they are their own property, to have done with them what they think fit—reproduced or enlarged—and it would be hard upon them if they could not. There is one thing that is often overlooked, which is that the negative, upon which the photographer may have spent much time in taking and retouching, is his property, although the copyright in it is the customer's. Any reproductions of prints from it are inferior to those he would supply. While the photographer possesses the negative he is in a position to supply, not only better copies, but at a less cost for production than the cheap copyist, inasmuch as the latter has first to make a new negative before he can print his productions. This same also applies to enlargements. Artists usually charge from thirty to fifty per cent. extra for finishing enlargements made from paper prints in comparison with those made from the original negative.

Should the Copyright Belong to the Photographer?

Some appear to consider that the copyright in a portrait which the photographer has been paid for taking should be vested in him. Such a thing would be manifestly unfair to the customer, as he would then be precluded from doing what he likes with what he has paid for. If he wanted copies or enlargements he would perforce, have to go to the photographer who took it and pay him any price he chose to charge, or go without altogether. He could not get the work done elsewhere at a price better suited to his means. It is, however, as we said in the former article, exceedingly gallant to the photographer who has spent time and trouble on the production of the negative to know that it has been reproduced and copies supplied at a very much lower price than his own. Our correspondent this week mentions copies as postcards at three shillings a dozen being supplied by the cheap copyist. Does this really injure the photographer? Those who have these cheap things are tempted by the price. If they did not have them at that very much question if they would have them at all. In very few cases, we surmise, would they go to the photographer and pay the price he would want for them; they would simply do without them, and the photographer would be no worse off. The same may be said with regard to cheap enlargements. Some cutting firms are doing cheap enlargements, 15 by 12 or so, for five and sixpence, from any photographs. It is exceedingly annoying to photographers to see enlargements from their photographs, of a size for which they would possibly charge a guinea and a half, or two guineas, or more (of course, of better quality) done at this low price. Here, again, we may ask if the photographer suffers the material loss from this sort of thing that many imagine he does? The people who have these things have them because the price is so low and within their means. It must not be supposed that if they did not have them they would invariably go to the photographer and pay his price for the work.

Is There a Remedy?

Our correspondent at the conclusion of his letter asks, "Where is the remedy?" We regret that, so far as we can see, there is no practical way of combating this cutting competition in the profession. If photographers were a more united body than they are, they might combine and make a much higher charge on the initial order, so that it would carry a fair

profit, regardless of prospective ones. They could then supply duplicates at a lower price than they do. They would also then be in a better position to combat the cheap copyist. There is no question that if people could get duplicates from the original negatives they would prefer them, and pay something more for them than for the cheap copies. But we fear, as things at present exist, this idea is impracticable.

* * *

The Northern Photographic Exhibition. Tuesday evening saw the opening of the third Northern Photographic Exhibition by the Lord Mayor and Lady Mayoress of Leeds (Councillor and Mrs. Robert Armitage) in the City Art Gallery of that city. No effort appears to have been spared, and no stone left unturned by the executive to make the show a notable success, and it should be deserving of all the patronage that a city of 450,000 inhabitants can give it. That the show is likely to be handi-capped as a financial success when compared with last year's Northern Exhibition at Liverpool, will be apparent when it is taken into account that the city on the Mersey is admittedly one of the most picture-loving centres in the kingdom, while Leeds—to say the least—is not. The Liverpoolians felt quite justified in asking one shilling admission to their show, and the inhabitants and visitors came in their thousands and paid their shillings cheerfully. Knowledge of the people of Leeds and of the great falling off in the attendance at the spring exhibition of the Leeds City Art Gallery (when one of the chief reasons assigned for the diminution in art interest was "the abolition of music in the gallery on Wednesday afternoons") has induced the executive of the present exhibition to charge sixpence only for admission, and half-a-crown for a six weeks' season ticket, which admits the holder to the show any and every day, and includes admission to eighteen concerts and sixteen lectures. In view of the fact, therefore, that the Leeds Camera Club will have to bear expenses quite equal to those of the Liverpool Society next year, it must be conceded that they have undertaken their task with commendable pluck, and we hope that the good send-off the exhibition received on Tuesday from the Lord Mayor and Lady Mayoress will ensure for it all the success it merits. A report of the exhibition appears on another page.

PRINTING PROCESSES.—VI.

P.O.P.

PRINTING-OUT paper being in such universal use and the subject of such general knowledge and experience, it may be thought almost a work of supererogation to include it in a series of notes on current printing processes; its widespread adoption might be supposed to have exhausted what there is to say about it. Nevertheless, there are some points of practice which are less commonly known than they appear or deserve to be, and there are also some new formulæ for toning baths which will bear repeating. The following article, therefore, while not professing to treat of P.O.P. from first to last, emphasises certain points in the process which make for its perfect working.

P.O.P. differs from the papers which have been hitherto considered in that the sensitive salts are not formed *in situ*, but applied to the surface of the paper in the form of an emulsion. The raw paper itself is first coated with a hardened emulsion of barium sulphate, which gives a perfectly opaque surface, so that the image lies entirely on the surface. Both gelatine and collodion are used as the vehicle for the silver salts, but the two papers prac-

tically require the same treatment except in minor details to be referred to later.

The manufacture of the emulsions presents no difficulty, and formulæ for the same will be found in the "Almanac" for the last three or four years. But coating is a far more difficult matter, and the idea—entertained, we are sometimes surprised to find, by intelligent photographers—that there is economy in making the paper on a small scale at home is a fallacy to be consigned to the limbo of other impracticable schemes, which are not uncommon in photography.

The sensitive salts used are silver chloride, an organic salt of silver such as the citrate, tartrate, etc., and free silver nitrate. The paper is far more sensitive than albumenised paper, and greater care as regards light must be, therefore, exercised in handling it, or the paper may take a general tint, which may prove troublesome afterwards. The surface is more sensitive also to dirty or greasy fingers.

It is impossible to lay down any specific rule as to how far printing should be carried, for each commercial paper probably has certain peculiarities of its own, and some lose more in the high-lights than others in toning and fixing, whilst others again lose depths in the shadows. For it must not be supposed that all papers, because they are labelled "P.O.P.," are alike. Some will give a greater range of gradation, others more contrast, and yet others differ in the depth between each step of the scale. Still, with all papers it is possible to alter slightly the character of a print by using a strong or a weak light, and the old dodge of using coloured glass or tissue paper over the frame alters the scale of gradation considerably, in that either the silver chloride or the organic salt of silver is principally affected.

Another point which must not be overlooked is that even the same emulsion when coated as "glossy" or "matt" paper produces a slightly different effect even when printed under the same negative; but very little experience is required to learn the idiosyncrasies of each and every kind of paper.

Whilst it is not generally adopted, so far as we know, there is no doubt that the best plan of washing the prints prior to toning is to immerse them at once in a solution of common salt. The first effect of this is to convert all the soluble silver salts into insoluble chloride, so that there cannot be any possible staining due to the free silver. The second effect must be economy—that is, supposing residues are collected—for all the silver that is not used for the image is obtained in the fixing bath. The treatment with salt also entirely obviates the formation of black spots, which are caused by rust or metallic particles from the water supply coming in contact with the free silver nitrate. Hence we recommend the addition of a little carbonate of soda to the salt solution, so as to neutralise the free acid which is generally present in the emulsion as a preservative. If, however, the prints are well washed after the salt bath, so as to free them from the excess of salt, there is no necessity for the soda.

There is one point in connection with the use of collodion papers which possibly we should not omit to mention, although it is hardly so necessary now as in the old days. Frequently this paper when immersed in water rolls up into a tight quill. If a paper is met with which has this peculiarity, the defect can always be prevented by placing the print face up in a dry dish and pouring hot water on to it.

The toning bath most generally used is the sulphocyanide, which, however, is not the easiest to work. The two chief points to be observed are, first, not to use too great an excess of sulphocyanide, and secondly, and the

more important point of the two, to make sure that the bath is "ripe." A ripened bath contains aurous sulphocyanide, whilst a freshly-mixed bath contains the auric salt. This latter salt eats out the details of the print. There is no difficulty in making a ripe bath at once, and, taking the average formula as:—

Chloride of gold	1 gr.
Ammonium or potassium sulphocyanide..	10 gr.
Water	10 oz.

the correct way of mixing this is to use boiling water, or else boil the bath when mixed. The gold should be dissolved in half the water, and the sulphocyanide in the other half, and the gold added to the latter in small quantities at a time, with constant stirring. There should be no red precipitate nor reddish tinge if the bath is mixed in this way. Both these may occur if the sulphocyanide is added to the gold, for sulphocyanide of gold is an insoluble salt, soluble in excess of sulphocyanide, and the aurous sulphocyanide is colourless.

For those who desire to keep a stock sulphocyanide bath, which is convenient when large quantities of prints are to be toned, Buhler's formula may be adopted. It is as follows:—

1. Gold chloride	15 gr.
Strontium chloride	150 gr.
Distilled water	1½ oz.

Heat to nearly boiling point.

2. Potassium sulphocyanide	40 gr.
Distilled water	1½ oz.

Heat to nearly boiling point, and then add No. 1 solution in quantities of two drachms at a time, stirring continuously. When all the gold is added, add sufficient distilled water to make 30 dr. in all. Every 2 dr. of this stock solution will be equal to 1 gr. of chloride of gold. This bath keeps well in the dark, and is ready for use as soon as diluted.

There are three other formulæ, which are, we think, more satisfactory than the sulphocyanide. The first is the phosphate bath:—

Sodium phosphate	24 gr.
Gold chloride	1 gr.
Distilled water	20 oz.

This should be mixed just before use.

The second bath is the formate:—

Sodium formate	15 gr.
Sodium carbonate	2 gr.
Gold chloride	1 gr.
Distilled water	20 oz.

This also can be mixed just before use.

The following bath is to be preferred even to the two foregoing, because it can be kept as a stock solution, and there is absolutely no tendency to double toning:—

1. Thiocarbamide	30 gr.
Distilled water	3½ oz.
2. Gold chloride	15 gr.
Distilled water	4 oz.

When dissolved, add sufficient of No. 1 to redissolve the precipitate first formed; this will be about 2 oz. Then add:—

Citric acid	55 gr.
Common salt	2½ oz.

and enough distilled water to make 7½ fluid ounces in all. Every half-ounce of this solution will contain 1 gr. of chloride of gold.

There are two points in connection with toning which should always be most carefully observed. The first is always to use distilled water, and the second is, to allow a definite quantity of gold to a definite area of paper. With regard to the use of distilled water, we feel sure that more troubles are caused by the use of common tap water than is generally believed. The second point is even more important still if uniformity of tone is required. Light prints will require less gold than others, but a fair average is to allow 1½ gr. of gold to every 480 square inches of paper.

Assuming that the prints have been treated with salt as already advised, and then well-washed, the quantity of toning bath containing the requisite proportion of gold should be measured out, and if necessary distilled water added to give a convenient bulk of solution. It is advisable not to attempt to tone too many prints at once, the number will depend to some extent on their size, but ten or a dozen is ample. They should all be immersed in the bath at once, and careful workers will see that the temperature of the bath is about 65 degrees Fahr. The prints then should be turned over and over till they have assumed the desired colour, which is usually judged by looking through, not at, them.

After toning, the prints may be thrown into a dish of clean water, or a solution of salt and water, and then washed. This is considered quite unnecessary by some printers, but we always advise it, and after the thiocarbamide and formate baths it is absolutely essential.

The fixing bath should always be rendered alkaline, either by the addition of a little ammonia or carbonate of soda, so that a typical formula is:—

Hypo	3 oz.
Strong liquor ammonia	1 dr.
Water	20 oz.

In this bath the prints should be left for fifteen minutes and continually moved about, so as to ensure perfect fixation. As much care should be exercised over fixing as over toning.

The combined toning and fixing bath has fallen into disfavour, not on account of its defects, but because of the careless way in which it was used; but provided the bath is not acid, and the prints are properly fixed, there is no reason why this bath should not be used. It is obviously useless to ensure neutrality or alkalinity of the bath and afterwards immerse acid prints therein; therefore we advise immersion of prints—to be afterwards treated in the combined bath—in the above-mentioned salt bath, to which some carbonate of soda has been added.

A neutral bath can be ensured by using the following formula:—

Gold chloride	2 gr.
Lead nitrate or acetate.....	10 gr.
Hypo	5 oz.
Chalk	¼ oz.
Water to	20 oz.

Another excellent formula without lead is:—

Gold chloride	2 gr.
Sodium tungstate or acetate	60 gr.
Ammonium sulphocyanide	100 gr.
Hypo	5 oz.
Water to	20 oz.

It will be noted that the proportion of hypo in the above baths is large; this is to ensure perfect fixation. If this takes place, and the prints are thoroughly washed afterwards, there is no reason to fear fading.

In our next article we shall consider platinum toning and the production of various tones on F.O.P.

SENDING PHOTOGRAPHS BY TELEGRAPH.

SOME problems there are which, in spite of many difficulties and failures, continue to exert their charm on a host of would-be inventors. Calling, as they do for the highest training and appreciation of the underlying principles, they can only be grappled with successfully by a very few. One of the most tempting but elusive of these problems is the transmission by electrical means of images, either direct from the focussing screen of a camera or from pictures or photographs. In the popular mind this result seems to be as feasible of accomplishment as the transmission of sound by the same ubiquitous agent (electricity); but the technical difficulties of the task are very great indeed.

Numerous are the patents which have been taken out for apparatus of this description, but the very basis which is common to all of them, and which, unfortunately, is the only possible starting-point at present, enforces limitation of the severest description upon its possibilities, and at once rules out, at least, at present, the transmission of direct images, especially of objects in motion.

The Principle of Electrical Transmission of Pictures.

To transmit an image electrically, we have to translate the various gradations of light and colour into gradations of electric energy, and, at the receiving end, these variations in the intensity or pressure of the incoming electric current have to be converted back into variations of light intensity, or colour.

Figs. 1 and 2. Reproductions of transmitted pictures by Dr. Korn in 1902 and 1904 respectively. The portrait is that of Dr. Korn, and was transmitted 2,200 metres.

As may be expected from the close relationship, if not to say, identity, between electricity and light, there are many reversible phenomena of inter-action which might furnish the starting-point of a practical method of light transmission, such as the phenomena of electro-magnetic rotation of the plane of polarisation and the various photo-electric effects, but so far only the modification produced by light on the resistance of selenium and a few other substances has been practically utilised in such apparatus.*

Partial Solution of the Problem.

Of early attempts to transmit line drawings, and even half-tones, which have been more or less successful, we may mention

Bakewell's copying telegraph (1847), the pantelegraph of Caselli (1856), Easton's and Amstutz's bichromate relief methods, Greville Williams's electro-chemical telegraph, and, lastly, Professor Korn's autotelegraph; but, in so far as in all these cases the original was either a hand-prepared line-drawing in special non-conducting ink on a conducting surface, or a reproduction in half-tone of an original negative, and was reproduced (with the exception of Korn's apparatus) by purely electro-chemical means, these attempts do not, strictly speaking, represent photo-electric transmission, and it is therefore incorrect to state (as does a photographic contemporary) that the difference between Bakewell's and Korn's system is a matter of detail only.

Fig. 3.

Professor Korn's apparatus, though necessarily still imperfect and capable of simplification, certainly marks an important step forward in the evolution of the problem under consideration, and even in its present form may be assigned a distinct commercial value. To reproduce an original film direct as a negative or as a positive transparency at will over a distance of some 500 miles or so within twenty minutes can barely be characterised as a laboratory experiment, and will suggest many important applications, social and technical.

The Korn System.

To turn to Professor Korn's method, we may say that his present apparatus is an elaboration of the method, published by the same worker in February, 1902, and it may not be out of place to shortly recapitulate the essential features of the system. The original film is wrapped round a glass cylinder, which rotates, and at the same time slides along its axis in the manner of a phonograph mandril. A suitable sensitive selenium cell, fixed stationary inside the cylinder, receives its illumination from a source of light placed externally, the rays of which, in a narrow bundle, traverse the film, and therefore impinge upon the selenium cell in greater or smaller intensity according to the opacity of that portion of the positive transparency or film negative just then passing the light. These variations of light affect the resistance of the selenium cell, and so alter the current flowing from a suitable battery through the cell to line and the distant receiver. Broadly speaking, the receiver only constitutes Professor Korn's claim to novelty. He found that the luminous discharge produced in modified Geissler tubes of a certain degree of exhaustion, whilst very highly actinic, shows comparatively

* To those who are more particularly interested in this question we would recommend Liesegang's "Beiträge zum Problem des Elektrischen Fernsehens" (Düsseldorf 1899).

great variations of intensity when slight alterations occur in the current feeding these tubes.

How the Picture is Received.

With this in mind, the Korn receiver is easily understood; the varying current coming from the sending station affects a galvanometer of the "moving coil" type, imparting to its "armature" a slight rotation, and therefore altering the distance between a prolongation point of it and a fixed point. If we now produce by well-known electrical methods a so-called "Tesla," or high-potential, high-frequency, current, and lead this current through a small Geissler tube and the above-mentioned gap between the two points to earth, then the discharge in the tube (and with it the actinic value of the light) becomes the more powerful, the smaller the variable distance between the two points, and vice-versa. The tube being enclosed (save for a small aperture) and suspended close to a cylindrical sensitive film revolving in perfect synchronism with the sending film, it follows that the photographic action upon this film varies exactly with the opacity of the original, and an accurate replica of the original must result on development of film.

I had an opportunity of inspecting the apparatus at this stage in 1902, and a short reference, as well as some criticism, was published in the July issue of the "Photogram" of that year. Since that time Professor Korn has greatly modified the details of his apparatus whilst retaining the guiding principle.

Steps in Advance.

The improvements which Professor Korn has lately introduced are all directed:—

1. To insuring the absolute synchronism of sender and receiver.
2. To increasing the working speed of the receiver, and
3. To diminishing the size of the integral portions, out of which the reproduction is eventually composed.

In the early forms of apparatus these small portions consisted of squares of 4m/m, and the appearance of the reproduction was, of course, of a pronounced mosaic character; now the little squares are but a $\frac{1}{4}$ m/m. in size.

Many of the most essential features of the apparatus are of purely electrical interest, and, however important, cannot be described here; but a short description of some of the leading portions of the machine, as now constructed, will be acceptable.

The synchronism of the two rotating cylinders is secured by the comparatively simple device of stopping the receiver-cylinder once during each revolution, and releasing it again by means of an electric impulse from the sending station. This prevents any difference in speed between the two stations from becoming cumulative, and, since the stoppage takes place at such a period of the revolution, when no portion of the sensitive film passes the Geissler tube, it will not affect the ultimate image. For this purpose the sensitive film is taken somewhat smaller than the circumference of the receiving-cylinder, so that then, when laid round the latter, a certain gap between the two edges of the film is left. Both cylinders are rotated by shunt-wound electro-motors, marked respectively 6 and 1 in Figures 5 and 6*, and the identity of the speeds of both motors is secured by so-called frequency-indicators, shown at 1 in Figure 5.* The motors are geared to the spindles of the two respective cylinders, so that for the transmission of the photographs each cylinder rotates about once in twelve seconds. The sending-cylinder (4), as shown in Figure 5, is made of glass, and, suspended inside it, may be seen the selenium cell (3), which is usually of the well-known flat type, consisting of two fine conducting wires wound in close proximity to each other on a slate or porcelain slab, and bridged over by a fine film of selenium. The light from a 100-candle-power Nernst lamp (5) is concentrated by a lens (2), so that the rays meet in more or less a point on the surface of the glass cylinder, round which the original positive (size 13 by 18 c/m.) is wrapped, the rays afterwards spreading out again inside the cylinder, and impinging upon the selenium cell. Of course this whole arrangement of cylinder and cell is protected from ordinary light by a suitable box. In the latest form of sending-apparatus the transmitting cylinder, however, is arranged vertically, and the selenium cell itself is fixed at the bottom of the cylinder, the light being reflected down upon it by means of a mirror, placed inside the cylinder itself. This selenium cell having a high resistance, even when illuminated, requires a comparatively powerful battery, and since uniformity of current is essential, it is usual to employ a battery of accumulators as the source of current.

A. W. ISENTHAL.

*These figures, with the conclusion of Mr. Isenthal's article, will appear next week.—EdsB. J.P.

THE WEEK IN HISTORY.

The Death of Daguerre.

I IMAGINE that the little town of Bry, on the Marne, presented an aspect, fifty-four years ago, little different to that which it wears to-day. There were no electric cars and no statue in the market-place to "Daguerre, artiste, peintre, chimiste, inventeur de la photographie." But the old château was there, and probably also the curious tangle of courts and alleys which make Bry a profitable haunt for the photographer. Madame sits out in the sunshiny street to-day just as she did, no doubt, on the morning (July 10) Daguerre was suddenly taken by the rupture of a blood vessel of the heart, from which he died within the hour. During his retirement at Bry, the inventor of the "Daguerreotype" received many visitors, chiefly photographers, from all parts of the world. One of the last to thus seek him in his picturesque home was Charles Meade, the daguerreotypist, of New York, by whom the last and most familiar portrait of Daguerre—that in which he holds his

hand to his ear—was taken. I mention this point, because the portrait in question is often attributed to Mayall.

Platinum in the Platinotype Developer.

I have chronicled the first and last patents by which the platinotype process was protected. Between them is another taken out by Mr. Willis on July 12, 1878, almost exactly five years after the first specification was left with the Patent Office. This second step in the process was marked by the employment of a salt of platinum in the developer as well as in the paper. Lead chloride was also a constituent of the coating mixture, but in the last patent of 1880 this ingredient was dispensed with, and the proportion of platinum on the paper increased to such an amount as to dispose of its presence in the developer.

Daguerre's Panorama in England.

I am indebted to Mr. A. F. Mowll, F.R.P.S., of Liverpool, who has forwarded to the Editors a copy of the "Liverpool Mercury"

of April 22, 1825, in which is advertised the Diorama of Daguerre, then being exhibited on the banks of the Mersey. The advertisement is interesting:—

THE PUBLIC are respectfully informed that the DIORAMA in BOLD STREET, is now open, with the View of TRINITY CHAPEL, in CANTERBURY CATHEDRAL.

This splendid Picture, originally exhibited in Paris, and afterwards in the Regent's Park, London, is the first of a series now executing by Messieurs Bouton and Daguerre, and which, after being presented to public view in those two Capitals, will be exhibited successively in this Town.

These two Artists have recently had the honour of being created Members of the Legion of Honour by the King of France, in testimony of his Majesty's admiration of their extraordinary

talents; but their great claim to a high and lasting reputation rests on the surprising merit of these magnificent performances, which they have entitled the Diorama, and of which they are the Inventors.

The Picture to which the attention of the Liverpool Public is now invited, is their first attempt in this new line of painting; but it has been pronounced by the best judges, both in France and England, to be as unrivalled in its execution as a work of art, as it is unprecedented in its character of an ingenious invention.

Admission, Two shillings—Children, under twelve years of age, Half Price.—Perpetual Admission Tickets (not transferable) during the Exhibition of this Picture, 7s. 6d.

Open from Ten till Dusk.

HISTORICS.

THE OPTICAL CONVENTION.

The following is the report of the discussion, following Lord Rayleigh's paper, on the "Polishing of Glass Surfaces," printed in our issue of June 23. Its appearance has been delayed by the necessity of revising the shorthand notes from which the text, printed

below, has been prepared. Our record of the proceedings of the Convention bearing on photography will be complete when we have given the discussion of Mr. W. Rosenhain's paper on "Possible Directions of Progress in Optical Glass;" and this we hope to do in our next issue.

THE POLISHING OF GLASS SURFACES.

Discussion of Lord Rayleigh's Paper read before the Optical Convention.

Mr. Rosenhain had listened with extreme interest to the remarks of Lord Rayleigh. He had already read in abstract Lord Rayleigh's lecture on the subject of polish, and since then, and since reading the work of Mr. Beilby, had been engaged in a number of experiments in the matter. In every way the observations that he had been able to make bore out the views which Lord Rayleigh had put forward, with one exception. He was not at all satisfied that there was no filling up of holes in the case of glass. In the case of metals, even of hard metals such as chilled steel, there was always this filling up, and in the case of glass there was some evidence to show that there was a surface flow under the polishing. He did not believe that particles of glass are removed from one place, transported to another place, and joined on again, but there was transference of the glass, a sort of smear along the surface in the direction of the polishing. A piece of glass that had been polished in what would be, for practical purposes, an unsatisfactory way was adopted for this experiment. It was polished in one direction only by rubbing in one particular direction, and when the polish was as nearly perfect as possible, such a piece of glass was attacked by hydrofluoric acid, using the precautions described by Lord Rayleigh, and there was undoubtedly microscopic symptoms of striation in the direction of polish which could not be traced before the etching. That was evidence of the same character as that found by Beilby, Osmond, and others, that in the case of metals surface-flow does take place. If the analogy were carried further, on the strength of this evidence, it would be fair to believe that the surface layer of glass goes to a depth considerably greater than Lord Rayleigh had suggested. In the case of metals, the depth was very appreciable. Mr. Rosenhain's observations had convinced him that it was greater than Mr. Beilby had supposed. He had been able to show recently that the surface smear was thick enough to be perfectly opaque. He had had occasion to polish sections of metal where there were two metals differing in colour and in hardness adjacent to one another, and one metal was smeared over the surface of the other in polishing. The more soluble was removed by an etching reagent, and patches of the smear of metal—in this case iron—were plainly visible on the surface of the other metal. There was absolutely no difference in the colour of the smeared portion superposed on the differently coloured metal from the colour of the polished and etched surface of the solid metal, from which he concluded there could be no appreciable amount of light coming through and back again. Consequently, he thought that the difference in hardness between iron and glass was not so very great. Hard steel was certainly harder than some of the softer glasses. There was every reason to believe that when the polishing action took place there was a distinct change of structure to finite depth. The polishing effect was not quite the same when you use a polished glass surface and a fire-polished surface, the polarisation effect being more uniform when you use the fire-polished surface than when you use the mechanically-polished surface. After all, it is only a question of the degree of perfection attainable. On the theory of Beilby and Osmond, there was no doubt that a rearrangement of the surface layer of the metal takes place in a very similar manner to what would take place if the surface was a fluid behaving under the

action of surface tension forces. This was a very slight modification of Lord Rayleigh's theory, and perhaps could not be accepted without a great deal of further inquiry. Further inquiry was needed, and the lines of it were fairly evident. Mr. Rosenhain considered, also, that there was some evidence to show that in the case of a polishing agent there was an action in which the polishing agent itself played a considerable part. He considered that there was some dependence between the nature of the surface produced and the chemical nature of the agent used as a polishing medium, though it was possible to modify the keeping qualities, the chemical stability of the surface, by adopting the proper polishing medium for the glass in question. He thought it might be impossible to show analytically that there was some actual layer of chemically different matter on the surface, but there was no doubt that, by modifying the conditions, the polishing medium could be polished at the expense of the glass or metal. He had certainly frequently seen that where the conditions of moisture, pressure, temperature became different from what they normally were, the surface of the glass, instead of becoming further polished, became actually roughened, and instead of a smooth surface being produced on the glass, it is produced on the layer of polish underneath. He believed there was a special trade name for that particular kind of mishap. It merely emphasised the point of view that there was some action, a chemical or atomic action, between the polishing medium and the substance polished, and for that reason it might be possible to alter the chemical behaviour of the surface, after polishing, by the use of a suitable polishing medium. Rouge and the other mediums generally used were not the only polishing media, and, he thought, not always the best that could be used for the purpose. Lechatelier has shown the use of alumina precipitated in a particular manner, and the oxides of various earths will act in an efficient manner as polishing agents. Some of them, however, which appear, apparently, to be every bit as fine and free from grit, have actually negligible polishing qualities, while some act very effectively, although from their appearance they would not seem likely to do so.

With regard to the slide Lord Rayleigh showed of the action of hydrofluoric acid, it was particularly interesting as explaining a process well known in the glass industry—the polishing of cut-flute glass. The glass was ground very finely on the wheel, and the polish was obtained simply by immersing the whole article in an etching solution of hydrofluoric acid and some saline substance; probably the composition of the bath was very much a rule of thumb. The glass went in matt and came out polished. He would certainly examine this glass under the microscope to see if it behaved in the same way.

Mr. Horace Beck had been extremely interested in hearing the paper by Lord Rayleigh, as he had been much interested in the subject of polishing in their optical works. The burnishing of surfaces undoubtedly appeared to occur in some cases. If the surface was not sufficiently smooth, if there were pits left in the glass in the first case, and then it was polished by a workman who put great energy and pressure into the work, you could get an effect in which the surface appears to be practically continuous, but underneath that surface was a comparatively large pit which seemed to fill in at the

top and was polished almost to the centre. The only way he could account for this was that the glass to a certain extent goes over the edge of the hole in the way Mr. Rosenhain had suggested. With regard to the question of how soon we can get a reflection from the gray surface by means of rapid polishing, he had frequently noticed in getting ready a lens that had been extremely finely smoothed, by simply wiping it over with rag it was quite sufficient to show the colours distinctly against another glass. The depth of the glass taken off must be quite of the amount which Lord Rayleigh mentioned, if not more. As to the polishing very slightly, there was a well-known trick which people try in a polishing shop. He had had workmen who had assured him that they had polished work fully, but when they really wanted work to be completely polished they could not keep good figure. That was in the old method of polishing. In modern methods, where one tested continually against the proof glass, the question of polishing the surface right up did not matter, because if there were a departure from figure it could be readily put right, but by the old empirical method, if it once got away it was very difficult to get back again. Messrs. Beck frequently use the method of slightly polishing the lenses when in doubt as to what the results would be. In a telescope object-glass, of which the calculations were doubtful, it was only sufficiently polished to permit of testing. It was astonishing how much light one can get through in this way with extremely little polishing—far less polish than Lord Rayleigh had on those he experimented with.

Mr. Beck had gone into the question of polishing unequal surfaces some time ago with the idea of making glasses to act like the so-called Japanese mirrors; he wanted to get a glass that would throw a pattern, and found that by very little faking one could cover over portions of the glass for a short time during polishing with a very thin material, and polish on and get no difference apparently on the surface of the glass, but the reflection would show the figure plainly.

There was no doubt that a different class of polish could be obtained by using different materials. The workshop men always considered that you got much more of a burnished surface if tripoli were used, than with a material like rouge or putty powder. There was also no doubt that a surface slowly polished seemed to be more perfect than a surface polished much more quickly. With regard to the question of the materials working into the surface of the glass and polishing over, this continually happened, and it was necessary to clean up with acetic acid to get it out. Acetic acid would very largely bring it out, and this was scarcely likely to affect the surface of the glass seriously, so that the amount of glass affected must be very small.

Mr. F. Tywman referred to the strain which occurred when a polished surface was made gray. In the case of a very thin piece of glass-gray on two faces, and polished on two ends, there would be a strain, and if the glass were 2 mm. thick the strain could be seen near each surface. If one surface were polished the strain would disappear and the glass bow up; on polishing the other face the strain entirely disappears, and the plate becomes parallel.

The Chairman (the Earl of Rosse), in proposing a vote of thanks to Lord Rayleigh for his paper, said that as another amateur polisher of glass and metals he had often found it very difficult to make a polished surface, or a surface he considered satisfactory, but which would not be looked at at all if it came out of an optician's shop. The difficulty was to get rid of scratches. He could understand that in a workshop, where one room was devoted to one particular process, and one workman works one thing and does not work another and is not going about amongst emery and sand, there is a much better chance of getting a good surface. His experience coincided with that of Lord Rayleigh, that the surface that does not look good to the eye is far better than one with a perfect polish, but not absolutely correct otherwise. In polishing flats he had found some with a good many scratches, but which when tested at night in the telescope gave very good definition. One of the objections appeared to be not so much loss of light as a sort of diffusion of light. If one wanted to look for a small white object like a star, the more light there was in the field the more difficult it was to see that small object. That might be partly due to the atmosphere and partly due to the defects of the surface. In working with metallic surfaces we were always under the disadvantage that a very good surface after a very short time begins to tarnish, and show a good deal of diffused light. When one worked with a mirror night after night in various kinds of weather, in a short time the surface became bad, and was never the same until it was re-polished.

ROYAL INSTITUTION.—A general monthly meeting of the members of the Royal Institution was held on the 3rd inst., Sir James Crichton-Browne, M.D., F.R.S., in the chair. The special thanks of the members were returned to Sir Andrew Noble, K.C.B., F.R.S., for his donation of £100 to the fund for the promotion of experimental research at low temperatures; and to Mr. Rollo Appleyard for his gift of a portrait of the late Professor J. D. Everett, F.R.S., M.R.I.

FORTHCOMING EXHIBITIONS.

July 4 to August 12.—Northern Photographic Exhibition. Secretary, F. G. Issott, 62, Compton Road, Harehills, Leeds.

July 15-25.—Sixth International Salon Association Belge de Photographie, Liège. Secretary, Mr. Servais, 34, Rue du Saint-Esprit, Liège.

August 7.—Andover. Hon. Secretary, W. I. Gradidge, Jubilee House, Andover.

August 24 to September 21.—Berwick-upon-Tweed Arts Club. Hon. Secretary Pictorial Photography Section, H. Hancock, 38, Ravensdowne, Berwick-upon-Tweed.

September 8.—International Exhibition at Budapest. Address, Secretary of the Photo-Club, Egyetem-ter 5, Budapest, IV.

September 15-October 21.—Photographic Salon, 5a, Pall Mall East. Hon. Secretary, Reginald Craigie, Camera Club, Charing Cross Road, W.C.

September 21-October 28.—Royal Photographic Society, New Gallery, 121, Regent Street, London, W. Secretary, J. McIntosh, 66, Russell Square, London, W.C.

October 28-November 4.—Sheffield Photographic Society. Joint Hon. Secretaries, J. W. Charlesworth, 1 Joshua Road, Sheffield, and James W. Wright, 62, Vale Road, Sheffield.

November 8-15.—Croydon Camera Club. Hon. Sec., W. H. Rogers, 88, Woodville Road, Thornton Heath.

November 14. 15. 16.—Ipswich Camera Club. Hon. Sec., R. H. Sutton, 37, Henley Road, Ipswich.

November 21-25.—Southampton Camera Club. Hon. Secretary, S. G. Kimber, Oakdene, Highfield, Southampton.

November 25-December 2.—Glasgow Eastern Amateur Photographic Association.

December 1-6.—Hove Camera Club. Hon. Secretary, A. R. Sarjeant, 55, The Drive, Hove.

December 12-20.—Southsea Photographic Society. Hon. Secretary, F. J. Lawton, 5, Pembroke Road, Portsmouth.

March 3-10, 1906.—South London Photographic Society. Hon. Sec., H. Creighton Beckett, 44, Edith Road, Peckham, S.E.

March 6-20, 1906.—Glasgow Southern Photographic Association, Hon. secretary, William H. Frame, 28, Bank Street, Hillhead, Glasgow.

FORTHCOMING COMPETITIONS.

July 15.—Warwick. Money prizes for members of photographic societies for pictures taken on Warwick Dry Plates. Warwick Dry Plate Company, Warwick.

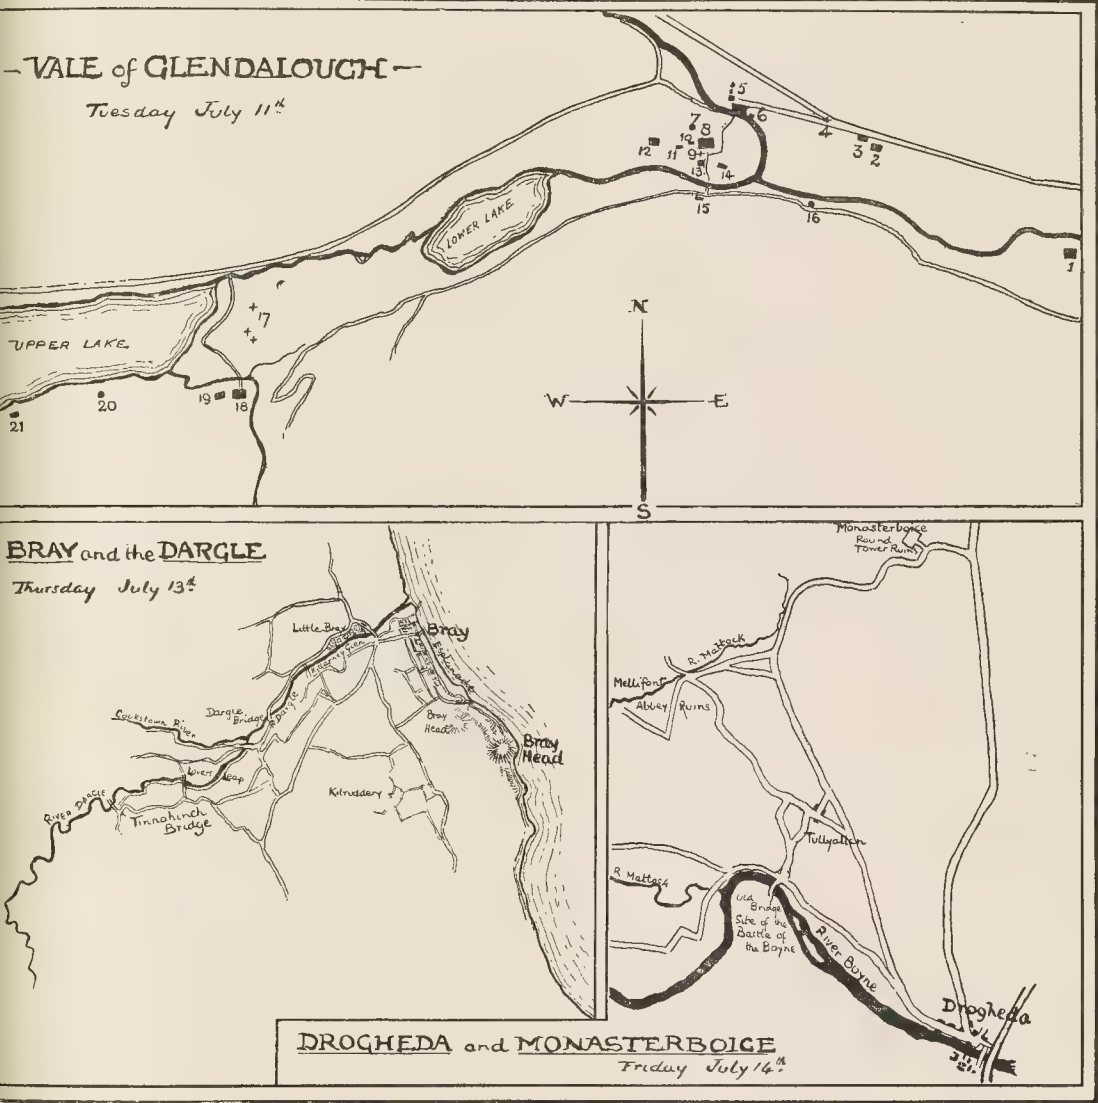

September.—Kodak. £400 in prizes for results on Kodak products. Kodak Ltd., 57-61, Clerkenwell Road, London, E.C.

October 1.—Thornton-Pickard. £100 in prizes for photographs taken with Thornton-Pickard cameras or shutters.

October 31.—"Zigo." Cash prizes for prints on "Zigo" self-toning paper. Thos. Illingworth and Co., Limited, Willesden Junction, London, N.W.

HURMAN, LTD., of 3, Victoria Square, Birmingham, inform us that they have purchased in its entirety the photographic business as carried on by Messrs. Philip Harris and Co., Ltd., Edmund Street, Birmingham, which business they propose transacting at their Birmingham house (Victoria Square) where they hold a complete stock of photographic apparatus and requisites, adopt up-to-date methods, and devote the whole of their attentions to photographic goods.

MANY Norfolk chemists (according to the "Chemist and Druggist") are finding picture postcards a valuable sideline, especially during the summer months, when the visitors flock to the Royal county.

THE PHOTOGRAPHIC CONVENTION.

DUBLIN MEETING, JULY 10 TO 15.

THE above maps are drawn up as an indication of the subjects for the camera to be found on the three chief excursions from Dublin.

Glendalough (Tuesday).—

Priory of St. Saviour.	12 Our Lady's Church.
Trinity Church.	13 St. Kevin's Kitchen
Site of Cloigtheach.	14 Site of St. Kieran's Church.
Stone Cross.	15 The Deer Stone.
Site of Market Cross	16 St. Kevin's Well.
Hotel	17 Stone Crosses
Cloigtheach (Round Tower).	18 Hotel.
Cathedral	19 Reefert Church.
Stone Cross.	20 St. Kevin's Bed.
St. Kevin's Yew Tree	21 Teniplenaskellig, or Dysartkevin.
The Priests' Church.	

Bray and the Dargle (Thursday).—It is impracticable to point out particular subjects. After Kilruddery (the seat of the Earl of Meath), the interest centres in the rocky glen, two and a half miles in length, through which the Dargle rushes, and from which occasional glimpses of mountain and vale are obtained.

Drogheda and Monasterboice (Friday).—

Monasterboice.—Tower, Three Crosses, Tombstones.

Boyne.—Obelisk, Site of Battle, Boats.

Drogheda.—Viaduct with Shipping, Magdalen Steeple, St. Lawrence Gate, St. Mary's Abbey, Maiden Tower.

THE ILFORD £750 COMPETITION.

THE following are the names of the prize-winners in all three classes of the recent Ilford prize competition. They are arranged in alphabetical order, as given by the Ilford Company.

Names of competitors who did not wish their names announced are omitted.

Competitors to whom extra prizes were awarded are included in the list.

We understand many prints were disqualified because the conditions were not complied with.

George Adamson, T. Aitken, Amateur Phot. Int. Soc. Ltd., H. Amon, Charles B. Anderson, R. Anderson, I. Angerhofer, A. W. Andrée, Captain R. Apostoli, S. C. Archer, Mrs. L. A. Armer, F. R. Armytage, W. Arkless, J. C. Asten, F. F. Austin, C. R. Avari, Frank Baker, Miss L. Baker, William Baker, Herbert Bairstow, A. Bakoulina, G. R. Ballance, C. G. Barker, T. S. Barker, Miss Olive Barnard, Mrs. G. A. Barton, Miss E. B. Basset, J. R. Batey, W. L. Beal, J. C. Beisly, F. H. Bell, A. E. Berg, A. M. Beschliaga, T. Best, W. E. Billington, Graystone Bird, Miss M. D. Bird, A. K. Blake, John T. Blackshaw, M. Blagowestschensky, Miss Blearsbach, James Blyth, W. T. Brass, W. Bratherton, J. Briggs, George Brown, Charles Burbury, Mortimer Burgess, R. Burnie, William Cadby, Sparham Camp, A. J. Campbell, C. P. Casstine, D. Cathcart, J. K. Cawsey, James Challiner, Ormond E. Challis, W. Chalmers, A. K. Chatterjee, T. Cheetham, F. G. Chetwynd-Palmer, R. Chika, H. B. Chinta, T. Clampit, H. Clark, Mrs. B. Clarke, Benjamin Clarke, Harry Clarke, Sergeant G. H. Cleaves, F. Cecil Cobb, Miss Constance Collier, Miss B. L. Collins, F. H. Collins, Rowland B. Cooke, A. W. Cooper, F. J. Cripps, Harry Cross, W. J. Culling, junior, P. H. Cundall, W. Cunningham, H. A. Curlton, A. W. Davis, F. Daw, G. Dawson, F. Day, Captain A. D'Azevedo e Silva, Ferdinand De La Bastide, B. Decker, J. A. De Jong, H. Dempster, Miss M. De Sauvayre, Ernest M. Dickens, C. A. W. Duffield, Dan Dunlop, Albert Durn, Miss Daisy Durn, Mrs. M. Preston Durn, F. W. Dyer, F. C. Eagle, David Eastwood, Josef Edelbauer, Miss A. Edmonds-Tozer, J. Goronway Edwards, M. M. Eglad, Oscar Ellquist, A. R. F. Evershed, Miss Ida Fairbairn, J. Fallow, Georges Favre, Miss Winifred Fink, Mrs. J. Finn, T. D. Folkes, R. M. Fortune, Charles Foster, A. Fox, John Fredriksson, Frederick Fry, Fujiwara, H. A. Game, J. P. Gangooley, A. B. Gardiner, Robert Gardner, F. Garland, A. W. Gelston, G. N. Gilbert, V. S. Godfery, Felipe Gonzales, W. Gordon, Ronald Graham, J. Green, J. H. Greenidge, junior, E. Griffiths, C. Grimaldi, W. Gundry, junior, J. F. G. Gunn, Rev. William Gunn, George Hadley, H. C. Hadley, A. H. Hall, W. T. Hall, Oscar Halldin, Miss Janet Hamilton, A. H. Hamm, A. Hands, H. W. Harmsworth, P. Harris, H. A. Biscoe Harrison, Miss Phillis Ivy Harrison, T. J. Hartnett, Miss Laura Harvey, H. A. Hatou, H. Hawkins, Albert Haynes, John Haywood, G. W. Heron, H. Hill, J. Noel Hill, J. G. Hobkirk, S. W. Hodge, Alfred Holding, R. Holliday, junior, Mrs. Frank Holmes, Miss Mabel Holmes, C. A. Hoppé, J. Hummel, J. H. Hummel, H. Hunt, Miss Jean M. Hutchinson, Harry Inkpen, S. Ishizu, B. Leslie Jackson, E. W. Jackson, B. A. Jadhao Bros., and Co., R. Janion, Carl Janson, J. F. Johnson, T. W. Johnson, G. E. Jones, Harold Jones, G. B. Kalelkar, Lewis L. Kellsey, Walter Kilbey, S. G. Kimber, Mrs. R. M. King, R. N. King, J. Knowles, Michael Kourbanoff, Georg Koxoold, Adolph Krch, H. Kuijk, S. Kutajima, Gilbert Laffair, Miss Lambert, W. Lambert, A. E. Lane, George A. Laver, G. C. Laws, H. C. Leat, Auguste Lefranc, W. F. Leicester, Claude Le Vaux, Alfred E. Lewis, W. H. Lindsay, H. Light, A. J. Linford, T. G. Lofting, Louis C. Login, M. N. Lohmann, Miss Elsie Long, Alfred J. Loughton, A. Lundström, T. Lürcher, A. E. Lovell, C. E. Lyon, Miss J. M. McGee, F. E. Mackay, R. P. McKean, D. F. Mackenzie, S. Macpherson, I. Makarius, John Makin, H. T. Malby,

Louis Mallitte, James Malynn, Miss Mansfield, Mrs. Manson, Ernest Marriage, Trevor G. Marsden, Charles Marshall, Robert Marshall, J. O. Mba, Miss L. G. Meachen, W. N. Melville, Alexandre Michailoff, G. J. P. Millar, junior, J. P. Millar, H. Mills, R. T. Mitchell, W. Mitchison, junior, S. C. Mitra, A. P. Monger, P. W. Morris, William Mortimer, F. G. Mudge, S. N. Mukerjee, Miss R. Murgrove, John D. Murray, S. H. Mytton, S. Nagao, Nande and Co. W. V. Nene, F. Niblett, G. B. Nichols, J. P. Nicol, J. M. Nisbett, Norischkine, D. Northall-Laurie, W. Northwood, Mrs. C. O'Connor, Miss Caroline Ofor, Miss G. von Ohlendorff, K. Okuda, Hugh S. Olive, G. Oneto, S. Onishi, J. T. Orloff, Harold Owen, Oscar Owens, W. Page, Cecil Palmer, C. Papé, Vishwanath Parkhe, F. Parkinson, H. S. Parsons, J. Patrick, Miss Clara M. Patterson, E. J. Peacock, B. J. N. Pershad, E. Phillips, Gordon Phillips, Miss H. Phillips, Harold Pickering, J. S. Pigg, O. Pike, Koloman Pinter, Clarence Ponting, C. W. Poulton, M. Y. Prentice, Miss May Preston, F. G. Price, H. S. Prince, A. Propsting, Arthur Prosser, Miss Kate Pulford, E. S. Purkis, H. S. Quekett, O. C. Quekett, R. Quintino, A. Ramsay, S. H. Ravenscroft, W. Reid, H. Rendell, A. Richmond, F. G. Ridge, J. T. Roberts, N. B. Roberts, P. C. Roberts, Miss Katie Robinson, Sydney W. Robinson, Miss Elsie Ross, W. Rouse, A. H. Rudge, Nigel King Salter, J. H. Saunders, C. R. Scanlan, J. Scott, Charles Scull, A. W. Searley, Miss Maud Shelley, F. E. Shipway, A. A'Court Simmonds, A. J. Slovinsky, Arthur Smith, Edwin Smith, junior, E. M. Smith, Stanley Smith, W. Smith, W. J. Smith, T. R. Somersford, C. Spence, H. G. H. Spencer, J. C. Stacey, Mrs. M. R. Staddon, R. W. Stafford, Thomas Steel, C. Stephenson, L. B. Stephens, Miss Hilda Stevenson, Victor Stouffs, T. H. Stoward, J. Ayton Symington, J. A. Talbot, Tamura, T. Tanimoto, Mrs. Tapscott, William Tasker, E. D. Taylor, J. A. Taylor, H. Thompson, W. Thompson, S. H. Tinker, Miss A. Tomlinson, Miss E. Tomlinson, Ishiyama Toyo, C. W. Traish, James Trevor, George H. Tricker, Z. Tsuji, J. G. Turnbull, Charles Turner, H. Tyler, R. F. Tyler, Cyril Ramsey Unger, V. M. Vesselago, Isaac Waddle, Benjamin Walker, C. E. Wallace, R. C. Wallant, Miss A. M. Walters, C. Walton, Rev. J. H. Walton, J. C. Warburg, Arthur W. Ward, C. Weaver, Mrs. J. Welford, A. E. Westead, W. V. Westlake, H. Weston, A. Wertscoff, J. W. Whaley, F. H. Wham, R. Wilkinson, J. Williams, Mr. and Mrs. J. Williams, J. Wilmore, H. Everard Winter, H. Winterton, Colmar Wocke, Miss K. M. Worrall, S. A. Wright, M. Yamamoto, S. Yamamoto, K. Yasaka, B. A. Zdvornitsky.

An exhibition of photographs selected from the work of the prize-winners in the competition will open to-morrow (Saturday), July 8, at The Modern Gallery, 61, New Bond Street, W., and remain open daily (Sunday excepted) from 10 a.m. to 6 p.m. until Friday, July 14, at 6 p.m. Admission free.

THE British Glass Industry.—It is rumoured in the "Pall Mall Gazette" that a five years' arrangement has been negotiated between the glass manufacturers of Belgium and those of Great Britain, whereby it has been agreed that Belgian firms shall not send into this country or the colonies rolled plate glass, rolled cathedral glass, or Muranese tinted and embossed glass, except to the order of British manufacturers, who include Messrs. Pilkington Brothers, Ltd., St. Helens; Messrs. Chance Brothers and Co., Birmingham; and the Glasgow Plate Glass Company. The effect of such an agreement would be that the English glass trade would be practically protected. Apart from any change of fiscal policy, prices would be increased by from a farthing to a penny per foot, keen rivalry between the British and foreign producers of these particular kinds of glass would be avoided, and the home market would be entirely controlled by the firms named. Development is also expected in the sheet glass trade.

Exhibition.

THE NORTHERN PHOTOGRAPHIC EXHIBITION.

THE third of the series of annual exhibitions organised by the Liverpool Amateur Photographic Association, The Leeds Camera Club, and the Manchester Amateur Photographic Society, was inaugurated on Tuesday last at the City Art Gallery, Leeds, with a conversation and reception given by the Right Hon. the Lord Mayor and Lady Mayoress of that city.

The original idea of the scheme to hold a northern photographic exhibition alternating between the three cities of Manchester, Liverpool, and Leeds, appears to have found its inception at Leeds among certain members of the Camera Club, and although steps were taken some years ago for a co-operative show on similar lines, nothing came of it until the matter assumed its present shape in the exhibition at Manchester in 1903.

The Liverpool version of the Northern Photographic Exhibition proved an undoubted success, and the Leeds Camera Club, coming next in order, is, in the present show, doing its best to excel its predecessor, and there seems every reason to expect that such will be the case. If hard work on the part of the executive, perfect organisation, and unity of interest, count for anything, the Manchester Society will find it an exceedingly difficult task next year to go one better than the exhibition now open at Leeds.

It is not quite clear, however, just what measure of support is given to the Society holding one of these exhibitions by the other two.

The entries from members of the other two societies would probably materialise in any case; and beyond the fact that each society in turn is responsible for a "Northern Exhibition" in its respective centre and follows the general rules and regulations laid down for the conduct of the shows by delegates from all three—which rules being very similar in form to those of many other provincial exhibitions—there appears to be at present no material advantage accruing from co-operation.

Each society appears to be entirely responsible for the internal organisation of its own particular exhibition, and all financial matters relating to each show are also entirely local. In other words, each exhibition is a purely local effort—certainly far reaching—but dependent and succeeding on its own merits and by the efforts of its own officers. The principal virtue of the alliance appears to lie in the negative support given by two societies to a third by keeping aloof while that society is in travail with its exhibition, and by not holding other exhibitions at the same time to detract from its strength.

Of course, the fact that the work and risk attached to running these exhibitions on the present ambitious scale happen but once in three years for each society, is a consideration, and there is the additional fact that clashing of dates consequent on an annual exhibition being held by all three is avoided; but it seems to us that the organisation as a whole would be on a sounder basis if the financial interests of the annual show were shared equally by the three societies. There is as much likelihood of a "slump" in photographic exhibitions as in anything else; and the society that "strikes a bad year" under the present conditions will probably find itself in an awkward position, considering the extensive outlay involved before the doors are opened to the public.

The active co-operation of the societies federated to the Yorkshire Photographic Union has, therefore, probably been of more service to the Leeds edition of this Northern Exhibition than the moral support extended by Liverpool and Manchester. Delegates from no less than twenty-three of the federated societies participated in the preliminaries of the show, and many valuable suggestions were forth-

coming, and since acted upon. In addition to this, these societies showed their appreciation of the work undertaken by the Leeds Club in actively advertising the exhibition extensively in their own districts at their own expense. In fact, with support such as this, and a hon. secretary with a gift for hard work and organisation such as Mr. F. G. Issott possesses, it will be no fault of the Leeds Camera Club if the third Northern Exhibition is not an unqualified success.

It remains to be seen, however, how the conditions which now govern the exhibitions will have affected the three participating societies after the first round is completed.

The Leeds Camera Club is in the position of being one of two large photographic associations in the same city, and the other (The Leeds Photographic Society) is probably the oldest organisation of its kind in the world; and although recrimination has been rife in the past, it is satisfactory to note that the hatchet has been buried for the nonce, and the present exhibition will at least have been instrumental in cementing the friendship of these two influential organisations.

The show is undoubtedly a great triumph for the Leeds men, and there is very little to cavil at in any direction. The general effect of the exhibition as a whole is good, and should go far to impress the visitor unused to displays of monochromatic pictures with the strides photography has made in late years.

The galleries are lofty and extremely well lit. The selection of pictures is good, and they are hung with no little effect.

The executive have done their work well in the decoration of the galleries, the original chocolate coloured walls of which have been covered to the height of seven or eight feet with a neutral green-coloured arras cloth and then surmounted by a broad white frieze and moulding. The effect is very cool and restful; and the other decorations are in the same good taste.

In the north room the collection of pictorial photographs exhibited at the St. Louis Exhibition is on view. This collection has been transferred to Leeds intact, with very few exceptions, and is now exhibited in England through the co-operation of the Royal Commission. The frames show considerable signs of wear and tear after their two voyages across the Atlantic, but we understand that they have been hung in as nearly as possible the same manner and disposition as they appeared at St. Louis, and, as the prefatory note in the catalogue states, "The chief idea of the presentation of the St. Louis pictures at Leeds has been to give the public in this country an opportunity of seeing the works by which the photography of Great Britain was represented in the recent World's Fair." The collection certainly embraces a variety of work of different styles, but whether it can be regarded as fully substantiating the claim to be representative of British photography at its best is another matter.

In the competitive section for pictorial photographs, hung in the South Room, there are 321 pictures on view. We learn that the entries numbered nearly one thousand, and although every picture passed before the judges the Selection and Hanging Committee had to make a rigorous excerpction to maintain the high standard set for the show.

A general inspection of the exhibits discloses the fact that many well-known pictures are again on exhibition, and that the amount of new work is not very great. A larger number of pictures in pigment processes appear than is usual at the average provincial exhibition, and landscape and portrait work are in the majority. The judges were Messrs. Reginald Craigie, Douglas English, B.A., A. Horsley Hinton, and Edwin Tindall, R.B.A., and there does not appear to be much amiss with the awards, although it is a poor exhibition, wherein it is not possible to find many other pictures that are equally deserving of the special distinction accorded to the prize winners, yet in the present show the Selection Committee

have done their work well, and the general average of the works hung is of a sufficiently high standard to have given the judges considerable trouble in arriving at their decision. Eight bronze plaques were placed at the disposal of the judges in the pictorial section, and two in the scientific and technical section. As, however, only one award was made in the latter, the pictorial section benefited to the extent of an extra award, and, as will be seen from the award list, two plaques have been awarded to the same exhibitor. We have on a previous occasion discussed the policy of withholding the exhibitors' names from the judges, as appears to have been done in this case, and can only reiterate that if an exhibition committee has not sufficient faith in the integrity and open-mindedness of the judges to place every particular concerning the pictures at their disposal, other judges should be selected. Of course, in the present case it may be that there were no printed lists or catalogues ready in time.

The award that is likely to arouse most comment and form a bone of contention for the critical is No. 295, "Mists of the Morning," by Jas. C. Batkin. This picture, which is a river scene with boats and a steam tug, is ostensibly a multiple tinted gum print. In effect it resembles an extremely weak and poor quality bromide print that has been "helped" by washes of pale tints of blue and pink, picked out with patches of Chinese white. Whatever it is, the handwork is very conspicuous, and although the tinting is not overdone, the result is merely "pretty," and it is very doubtful whether the end achieved in manufacturing this pictorial "photograph" was altogether worth the labour evidently spent upon its production. It is not good photography, and it is very questionable art. Two other pictures by Mr. Batkin are on view, and both are much finer examples of photographic work than the print securing the award. No. 399, "A Dutch Canal," is a very fine little picture indeed, full of light and atmosphere, and, although a gum print, is clean in treatment and with not too much evidence of handwork.

John H. Anderson is the exhibitor previously mentioned to whom two awards have been made. No. 251, "A Harbour, Low Tide," is another gum print of good quality, but somewhat heavy in treatment for its size. It is hung rather high, and is consequently rather difficult to see and appreciate. No. 529, "On the Banks of the Lea," is a decorative little study of rows of straight trees. The foreground is a trifle incomprehensible, but the picture is distinctly pleasing.

It is noteworthy that nearly all the awards have been made to fairly small pictures, and the tendency has been to accept them on their face value without reference to the means of production. No doubt the judges thought—and rightly—that the onus of selection or rejection fell upon the Selection Committee, and their function was simply to judge what was put before them. The influence of the artist-judge (Mr. Tindall) is therefore very apparent in the awards, and although the "pictorial-effect-by-any-means" exhibitor scores heavily in consequence, the effect on the photographic technician must be distinctly discouraging. The award to Daniel M. Filshill will probably be very popular. The picture securing it is entitled "Eventide," and is dramatic in effect. A woodland scene with the setting sun streaming through the naked branches make a very striking study of luminous shadows.

J. M. Whitehead secures an award for his delightful little landscape, "Solitude," which amply demonstrates how a picture can be secured by straightforward photography from extremely simple material. "The Banks of the Somme," by Mr. W. M. Coultas, is a fine open landscape treated in a broad sketchy manner, and is well deserving of its award, and a "Portrait Study," by Dan Dunlop, is also a notable exhibit. It is a fine head study of an old man, but is somewhat marred by the frame being too light, and the figure seems too crowded in the space at disposal.

"The Spate," by A. C. Milne, is another medalled picture that is likely to be popular. It gives a marvellous effect of the rushing river tumbling through the arches of a bridge. The idea of motion is excellent and the composition is noteworthy. No. 530, "The Tiffany Glass," is likely to arouse comment. It is by Enid T. Brailsford, and depicts a little girl seated on the floor and regarding a brilliant glass ornament. The picture is very low in tone, and the only bright spot is the object in the child's hand. Two of the most striking pictures in the show are by the president, Charles B. Howdill, A.R.I.B.A. They are also the largest. One is entitled "Finishing the Plaque," and represents Mr. Caldwell Spence, a well-known Leeds artist, at work putting the finishing touches to the large decorative plaque that forms the award in the exhibition. As a composition it is not so good as Mr. Howdill's other picture, "The Modeller," depicting the same artist at work on a small clay figure.

It is impossible, in the space at our disposal, to give a detailed account of exhibits, although the works of a few can well be named for outstanding merit. Herbert Bairstow, Mrs. G. A. Barton, Arthur Marshall, A. Dawson Berry, Graystone Bird, Robert Bourke, W. Foster Brigham, T. F. Brogden, Thomas Carter, W. A. Clarke, S. L. Coulthurst, W. Crooke, J. H. Gash, W. T. Greatbatch, C. F. Inston, F. G. Issott, F. Judge, Adolph Langflier, Hector E. Murchison, David Murray, Arthur Peck, William Rawlings, Francis Rust, Hilda Stevenson, W. H. Stewart, W. Thomas, and C. E. Walmsley are responsible for noteworthy pictures, and there are many others.

In Section B., technical and scientific photographs, only one award was made. This falls to Arthur C. Banfield for his well-known series of photographs depicting "The Life History of a Splash," and are probably as good as anything of the kind possibly can be. This section includes the only tri-colour print in the exhibition, and, considering a special award was set aside for tri-colour work, and a section reserved, it is somewhat disappointing to find such an insignificant response.

This section contains some excellent photographs of natural-history subjects, and the works of W. Morley Martin, E. Seymour, O. G. Pike, Walter Bagshaw, Jasper Atkinson, and John Moore are conspicuous.

In the West Room is an interesting collection of photographic work by members of the Cape Town (South Africa) Photographic Society. No less than thirty examples of pictorial photography were sent over from the colony, and, although all of it is not up to exhibition standard, it shows that the South African photographers are going ahead and will soon be a power to reckon with.

There is a good number of entries in the Lantern Slide Section, and two plaques are awarded for pictorial slides, and two for scientific and technical work. W. H. Goy takes one of the first for a set of landscape subjects, and H. Wormleighton takes the other for an architectural set of high quality.

P. P. Wilding scores in the scientific section for a set of clever photomicrographs, and Godfrey Bingley for a set of geological slides.

A beautiful set of tri-colour slides by Miss Acland are on view with the other slides, but they arrived too late for cataloguing.

The trade exhibitors in the Staircase Hall include Messrs. Reynolds and Branson, Ltd., 14, Commercial Street, Leeds, who show "Rystos" electric and gas dark-room lamps, "Rystos" stand developing trough, "Rystos" portable developers, etc., etc.; Zeiss, Ross, and Goerz lenses; Sanderson, Dallmeyer, Watson, and other well-known makes of cameras; portable book illustration copying apparatus. Messrs. John J. Griffin and Sons, Ltd., 20 and 26, Sardinia Street, London, W.C., who have a wall display of portrait work made on Griffin's bromide paper (A1 snow-white rough surface). The Autotype Co., 74, New Oxford Street, London, W.C., show some fine "Autotype" enlargements from amateurs' negatives. The Paget Prize Plate Co.,

d., Watford, exhibit prints on "Paget" self-toning glossy; prints "Paget" prize P.O.P.; prints on "Paget" self-toning finished platinum; prints on "Paget" Gravura (gaslight) paper, matt; "Paget" prize post cards, S.T. matt, glossy, Gravura, P.O.P.; "Paget" S.T. matt, washed and fixed only; prints on "Paget" bromide paper; and prints on "Paget" toned bromide paper.

In the West Room, Thomas Illingworth and Co., Ltd., Willesden, London, N.W., have a stand in which they exhibit and demonstrate "Zigo" gelatino-chloride self-toning paper; "Illingworth" bromide paper; examples of different grades, smooth, rough, enamel, etc., etc.; carbon enlargements on "Illingworth" carbon tissue and the Gravure tissue.

Other stands are occupied by Taylor's Drug Co., Ltd., Leeds, London, and Bradford, who exhibit "Klito" cameras of 1905 pattern; and cameras of Sanderson make; roll-film developing tank; Messrs. Taylor's special solutions and chemicals, etc. Messrs. Pearson and Wham, 21, New Station Street, Leeds, who exhibit "The Loidis" hand and hand cameras; the "Kalee" Reflex, with focal-plane shutter; the "Sanderson" hand and stand cameras; and cameras and lenses by all the best-known makers. The Bayer Co., Ltd., Manchester and Bradford, who exhibit special "Edinol" developer for papers; "Edinol-Aristo" developer; acetone-sulphite; Bayer's flash-powder; Bayer's gum (powder); three gaslight papers, viz., St. Luke's, and Pan; Bayer's bromide paper; and "Aristo" paper. W. K. Upwith, 112, Albion Street, Leeds, who exhibit Sanderson Teak and angular cameras, Tudors, Klitos, Holborns, Victors, Busch cameras, and many other novelties.

In this room the wall displays are by the "Manchester Guardian" Printing Works (Taylor, Garnett, Evans, and Co., Ltd.), Blackfriars Street, Manchester, who exhibit specimens of photo retouching for process blocks; specimens of half-tone printing, three-colour block printing, and commercial photography. James Bacon and Sons, 38, Commercial Street, Leeds, who exhibit pastel portraits, miniatures, and gum-bichromate work; and C. R. H. Pickard, 5, Park Lane, Leeds, who exhibit enlargements in bromide and carbon, architectural photographs, technical and commercial photography, designs catalogues, etc.

Some interesting exhibits are shown in cases in the South Room. They include specimens of Daguerreotype apparatus, Hislop's camera taking microphotographs (1852), old waxed paper negatives, calotype negatives, silver prints on plain salted paper and on albumenised paper (1850 to 1853). Examples of early photographic work (1850-1860), by the late G. F. Robinson, of Newcastle-on-Tyne (a worker under one of the original Daguerre licences). Paper negatives by the calotype process, and prints in albumen, including negatives and prints of the great fire in Newcastle (1854).

Special mention must be made of the fine Exhibition Catalogue, which must have been a matter of considerable labour for the secretaries and the chairman, who, we understand, were responsible for its production. It is a bulky book, admirably and artistically printed and embellished with thirty excellent full-page reproductions of the pictures on exhibition, in addition to numerous marginal line sketches. The frontispiece is an admirable photogravure from one of Mr. Thomas Taylor's gum prints, "Rain on the Hills," and an excellent three-colour reproduction of Turner's "Fighting Temeraire," by André and G. Ltd., of Bushey, Herts, is also included.

It is due to the untiring efforts of the executive council, who have worked hard to ensure success, and they are to be congratulated for having secured an hon. secretary of such ability and enthusiasm as Mr. F. G. Issott.

Lectures and lectures will be given at frequent intervals during the weeks the Exhibition is open, and the only thing that remains to be done to make it a complete success is a liberal patronage by the public of

Leeds and district, compelling the council to provide a number of the guinea pictures that are to be given to every 1,000th visitor to the show.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

THE following applications for patents were made between June 19 and 24.

CINEMATOGRAPHY.—No. 12,613. Improvement in cinematograph apparatus. Charles Urban, 48, Rupert Street, London.

EXPOSURE REGISTER.—No. 12,815. A shutter exposure register for cameras. John Berstall, 37, West Nile Street, Glasgow.

PIGMENT PRINTING.—No. 12,867. Pigment printing process. Emil Bühler, 1, Queen Victoria Street, London.

CAMERAS.—No. 12,878. Improvements in photographic cameras. George Andrews, 24, Southampton Buildings, Chancery Lane, London.

DEVELOPING.—No. 12,951. Improvements in photographic developing apparatus. Thomas Gower Bergin, 37, Chancery Lane, London.

PRINTING PROCESS.—No. 13,032. Improvements in printing and developing photographs on silver chloride paper. Herbert John Mallabar, 6, Lord Street, Liverpool.

COMPLETE SPECIFICATIONS ACCEPTED.

Specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

WASHING PLATES AND FILMS.—No. 16,851, 1904. The apparatus, to be used both for washing and drying, consists of two frames (a), made up of upright bars (b), hinged together at their upper ends by hinges (d) of any suitable kind, and horizontal or transverse bars (c). When the dryer is in the position of use, the two frames are moved apart about their hinges (d), with their lower ends resting on the table or other surface; and they are kept apart at the required angle by link hooks (e), hinged at (e'), at one end, to one of the frames (a), with their others or hook ends fitting over pins (f), or into eyes or the like, on the other frame. If the hook links (e) be unfastened, the two frames (a) can be folded flat upon one another, and in that condition be put away, packed, or carried, and will occupy little space. With regard to the construction of the supporting part on the upper edges of the cross bars (c), in that shown in figures 2 and 3, it consists of perforated metal bars (h), let into and fixed in the cross bars (c), and splayed out upwardly and outwardly, in opposite directions or inclinations; and the lower edges of the negatives, etc., to be dried, rest on these bars (h) slightly above the bottom of the angle where the two bars (h) come together and touch. The water or moisture, which, when the negatives are placed on the bars (h), flows or creeps down to their lower edges, can, in the first place, drain away through the openwork plates, and secondly, the air can get full and free access to these lower edges, and will absorb the moisture and carry it off, so that these lower edges of the negative will rapidly dry, i.e., in less time than is occupied when drying by apparatus as commonly employed. The dryer is constructed to hold two sets or tiers of negatives, etc., in each frame (a), namely, one on the lower bar (c), and another on the upper bar (c), and they are supported at a point above these bars by the metal or other cross bars (i),

fixed in the bars (b). It will be obvious, however, that the frames may be constructed to hold only single sets, or two or more sets, and these parts can be made of any suitable material or materials. William Lawrence Parkinson, 3A, Imperial Chambers, 62, Dale Street, Liverpool.

Fig. 1.

Figs. 2 and 3.

AUTOMATIC SETTING OF ROLLER-BLIND SHUTTER.—No. 3,162, 1905.

The shutter is set by the act of inserting the dark slide into the camera back. As the dark slide enters it first lifts a rack (e), thereby bringing the same into gear with a toothed wheel (f). By completely pushing home the dark slide the latter impinges against a lug (g) and carries the toothed rack (e) along with it so that the wheel (f) is rotated, and by means

Figs. 1, 2, and 3.

of the shaft (i) similar motion is imparted to the roller (d) (fig. 3) of the shutter (c) in the required direction for setting the latter. When the dark slide is completely home, the shutter (e) is fully set and ready for the exposure. The operation or release of the shutter to expose the plate is effected by a two-armed lever (o) (fig. 2) pivoted at (n) and arranged to act in such

a manner as to disengage the toothed wheel (m) from the toothed wheel (l) when moved by hand in one direction, thereby releasing the shutter. The arm (o) is returned to its initial position by suitable means such as a spring. The rack (e) is returned to its initial position by a spring when the dark slide is withdrawn from the camera. Adolph Richard Lange (of Emil Wünsche Aktiengesellschaft für Photographische Industrie, Reick, Dresden), 50, Dresdner Strasse, Laubegast, Dresden, Germany.

BORDER NEGATIVES.—No. 1,286, 1905. The claim is for an ornamental border negative having an opening which is covered by an exchangeable panel or sheet, on which is a transparent inscription on an opaque ground. When a sensitive paper is exposed to the light through the negative, a photograph will be produced of the ornamental border design and at the same time of the exchangeable printed matter, or of any other subject, that may appear in transparent lines on the exchangeable strip or sheet. Hugo Kuntzen, 92-96, Bishopsgate Street Without, London.

New Apparatus, &c.

The "Idento" Camera. Made by Adams and Co., 26, Charing Cross Road, London, W.C.

The desire of the amateur photographer to possess a hand camera that combines all the movements and adjustments usually associated with the field camera, and yet at the same time sufficiently small and compact to be carried in the coat pocket, is the problem that has for many years been the aim of the camera designer and maker.

to meet. So far the attainment of compactness and portability have been at the sacrifice of some important feature. In the new camera Adams and Co. have now introduced under the name of the "Idento," the acme of portability appears to have been achieved without sacrificing any one essential that goes to make a really high class and reliable instrument, capable of being employed not only as a hand camera, but in a more extensive field of operations. It is claimed, and the claim seems to be fully substantiated, that the "Idento" is the smallest complete folding or pocket quarter-plate camera ever designed.

One of the most striking of the new features introduced in this camera is the new type of finder—the Identoscope. When using the Identoscope finder, the identical view can be seen as it appears upon the plate, at all times, even when the rising fronts are used, either horizontally or vertically. It can thus be seen to what

quired extent the rising front need be used. A satisfactory and viceable rising front upon a hand camera loses its principal value, less the user is able to see what picture he is getting upon his plate. This feature will, therefore, be appreciated by every hand camera worker.

Each camera will take, without any alteration or addition whatever, either a changing box, double dark slides, daylight loading holder, or Premo daylight loading film pack adapter. Thus any number of plates, flat, or rollable films, may be carried and used, and at the same time it may be used as a stand camera, and objects focussed in the ordinary manner upon the ground glass focussing screen, which is fitted with a folding hood, protecting the focussing screen from light all round it. The instrument has vertical and horizontal rise and a level for horizontal and vertical pictures. The camera focusses from various close distances to infinity by a novel rack and pinion arrangement which ensures great exactness. The shutter gives exposures from $\frac{1}{2}$ sec. to 1-100th sec., also time exposures. It opens and closes to the centre, without vibration, and is fitted with a protector. When the camera opens it is as fixed and rigid as a box camera, and can be most conveniently held and manipulated. When closed, the camera is particularly small and neat. The lens is completely protected and does not protrude. The Identoscope holder is also self-contained inside the camera.

A plate can always be carried in position, ready to receive an exposure. The camera can be opened and closed very quickly. It focusses out to its infinity distance, therefore is at once ready for ordinary work, without the trouble of adjusting the focus. It is roughly well made, best workmanship and materials being employed, and is beautifully finished and covered in morocco black leather.

The complete camera body, together with lens, shutter, Identoscope, finder, and carrying handle only measures, when closed, $1\frac{1}{2}$ in. thick, $5\frac{1}{2}$ in. long, and 4 in. wide, and weighs about 20 oz.

The price, including a 5 in. Ross Homocentric Lens, is £15, or if ordered with order £12 12s., which cannot be considered excessive if the workmanship and personal attention that has been bestowed on this camera is considered.

A SERIES of showcards for photographers' establishments is a new one with Messrs. H. and W. Green, Crown Photo Works, Rotherham. The cards are olive green, with the lettering clearly blocked in silver, and cost only 1s. for three, post free. The following mottoes are obtainable:—Deposit to be paid at time of Sitting; Children's Portraits a Speciality; Picture Frames made to order; Enlargements in any Style; Best Style and Finish Guaranteed; Gem Midgets, 6d. per dozen; Victoria Midgets, 1s. per dozen; Any Photograph Copied and Enlarged; Portraits taken Day or Night; Wedding and other Groups Photographed.

RACING with Postcards.—A postcard race round the world has just been organised in Paris, as a practical test of the utmost that can be achieved in the way of speed. The "Globe" states that 100 postcards were put into the post on Saturday last by as many different competitors, and their dispatch was duly registered. They were addressed to as many prearranged correspondents in all parts of America and of the Far East, and are travelling some by Marseilles, some by Cherbourg, and some by Southampton. On reaching their destination, the cards will be readdressed and reposted for Paris. The competitor receiving his card back first wins the prize. M. de Laffitte has organised the competition.

FIRE broke out one day last week at a photographic studio in Mottramley Street, Manchester Road, Bradford, occupied by Mr. J. Brown, soap maker. A portion of the studio was burned down, and a camera was destroyed.

News and Notes.

A SUGGESTION of interest to all Londoners has just been put forward in a pamphlet by F. W. Speaight, photographer, of 157, New Bond Street, London. It is the formation of a semi-circular space, 360 ft. diameter, immediately behind the Marble Arch, on land at present enclosed by the park railings. If this were done, all the traffic to and from Paddington, via Park Lane and the Edgware Road, would be able to take a direct line by passing at the back of the Arch, instead of the front. It would also allow the traffic leaving the park to branch off to the right or left of the crescent without having to come first in front of the Arch, as at present, and the acute congestion of traffic at the Arch would therefore be relieved. In addition to this, the Arch would stand out boldly by itself in the middle of the crescent, occupying a position somewhat similar to that of the Arc de Triomphe in Paris, and certainly not inferior to those occupied by any of the triumphal arches in France, Italy, or Greece. Further, the alteration would make a dignified finish to a grand processional road, which would start with Sir Aston Webb's beautifully designed Trafalgar Square entrance to the Mall, along that splendid thoroughfare to the Victoria Memorial, Constitution Hill, and the Wellington Arch, and then through Hyde Park to its finish at the Marble Arch. Mr. Speaight suggests that the screen which separates the crescent from the park should be given an international character, and should commemorate the efforts made towards international peace by King Edward VII. The circular announces that Mr. Speaight will feel honoured by being allowed to guarantee 500 gs. towards the scheme. The large drawings and plans reproduced in the pamphlet can be seen at the galleries, 157, New Bond Street, London, W.

PHOTOGRAPHY and Gambling.—A camera played an important part in an elaborately planned raid on 400 gamblers which the police carried out on the Humber bank, near Grimsby. For many years the Humber foreshore (according to a "Daily Chronicle" correspondent) has been the resort of large numbers of men and youths, who spend their Sundays in playing games of chance. Determined to check the evil, the borough and dock police forces co-operated on Sunday last, and under Inspector Moore made a great raid. Early in the morning a large force of plain-clothes officers concealed themselves along the railway sidings beneath the river banks, and in a convenient hollow along the shore. There they lay hidden until ten o'clock, by which time quite 400 men and youths were spread in groups along the shore, playing various games. A plain-clothes constable, armed with a camera, walked innocently amongst the players, snapping the different groups, who, unsuspecting his purpose, subjected him to a good deal of chaff. When he had used all his plates, a police whistle sounded, and constables descended upon the astonished gamblers from all quarters. The players ran off in every direction, but over 100 were captured. Many fled to the mud-flats left by the tide, but a group of officers sat upon the bank, and calmly waited until the fugitives, tired of their damp and dirty retreat, limped ashore and surrendered. They will be summoned, and the constable's photographs used in evidence against them.

HOUGHTONS' Annual Outing.—The head office of Houghtons, Ltd., of 88-9, High Holborn, and the optical branch at 95, Hatton Garden, were closed on Saturday, June 24, for their annual athletic sports. The meeting was held at Broxbourne, on the banks of the River Lea, and in the lovely old grounds of the Crown Hotel about 200 of the clerical and warehouse staff spent a really enjoyable day at the firm's invitation. A special train left Liverpool Street at 9.29, and the programme was commenced at eleven o'clock sharp. The events

before lunch included 100 yards sprint in four heats, a thread-needle race, a mile walk, egg-and-spoon race, quarter and half mile races, and a ladies' tug-of-war. Then came the all-important lunch, at which Mr. Edgar W. Houghton presided. The Chairman took an opportunity of making a brief but interesting speech, in which he pointed out to the staff to what a great extent the success of a business like theirs depended on the co-operation of all workers in the company, from the highest to the lowest. Telegrams were read from Mr. George Houghton, senior, who was unavoidably absent, from Mr. Fred. Isaacs, who was away on his honeymoon, from the Vice-Chairman, and from the Glasgow branch of the firm. Mr. W. Edwards replied to the Chairman's speech, and the "Ensign whisper" was given with a heartiness that startled the neighbourhood. After lunch the sports were resumed with a sack race, three-legged race, 200 yards race for married men, ladies' backward race, and tug-of-war between teams selected from the warehouse and the office. This last event resulted in a win for the office. Subsequently the prizes were presented to the winners by Mrs. W. Edwards, groups were taken, and then the company sat down to tea. The long June evening was spent on the river, and the return train to town left at nine o'clock. The weather was perfect, and a more enjoyable staff outing could not have been imagined.

BICHROMATE Poisoning.—An inquest was held at Oldham recently relative to the death of Kate Barton, who died from poisoning by bichromate of potash. A doctor stated the deceased told him she had taken three pieces of the bichromate, some of which she gave him. He added that he had never known an instance where bichromate of potash had been used as poison before. One-fifth of a grain was enough to kill her, and she must have taken about 36 or 40 grains.

BERWICK-UPON-TWEED Arts Club.—The second exhibition of painting, sculpture, architecture, and pictorial photography, under the auspices of the above club, will be held in the Artillery Hall, Berwick-upon-Tweed, from August 24 to September 21. Particulars and entry forms may be obtained from H. Hancocks, 38, Ravensdowne, Berwick-upon-Tweed, hon. secretary to the exhibition committee.

The latest list of the Aldis Anastigmat lenses reaches us from Aldis Bros., Old Grange Road, Sparkhill, Birmingham, and contains, we find, a good deal of useful information which is not an invariable constituent of lens-makers' catalogues. For instance, there is a table of dimensions of the Aldis Anastigmats, in which the outside diameter of flange, the total length of mount and diameter of hood, with also the distance from face of lens-board to screen when camera is set for distant objects are all conveniently set forth, and the data should be of service to those purchasing a lens to fit a particular camera. The list, which is sent post free, contains a number of half-tones from excellent photographs taken with the lenses.

THE "Zigo" competition.—Messrs. Illingworth have asked us to draw attention to rule 4 in the printed regulations, etc., of the forthcoming competition for prints on "Zigo" paper. This rule should now read:—"All unsuccessful prints will be returned, provided the senders enclose stamps for return postage."

The award list of the International Exhibition at Genoa is to hand. The six highest awards (gold medals) have been made to: Guido Rey, Torino; Alfred Orrano, Genoa; Alexander Keighley, Keighley; T. O. Hofmeister, Hamburg; C. Puyo, Paris; and F. J. Mortimer, London.

The Agricultural Show at Armagh, held 28th and 29th ult., was very well attended, and proved a great success. The awards in the photographic section were made to Misses Haslett (Portraits), J. B. Anderson (Landscape), Hugh Cochrane (Any other subject), D. W. Elliott, T. Bryans (Focal plane work).

COPIES of the illustrated booklets published for the town council of Rhyl, Malvern, Bexhill, and Southend, which, in view of the approaching holiday season may interest our readers, will be sent free if a postcard request is sent to the respective town clerks.

SOUTHAMPTON CAMERA CLUB.—The committee of the above has for their summer programme relied this year upon their own members very largely, and with excellent results. At the fortnightly meeting held on Monday, the 3rd inst., Mr. C. C. Cook read a most interesting paper upon "Photographic Dodges."

A FIRE broke out last week on the premises of Mr. Edwards, photographer, of Free Street, Brecon. A large quantity of photographic apparatus, photographs, and household articles were destroyed, the damage being estimated at about £200. Mr. Edwards, who is not insured, unfortunately loses about half of this sum.

Commercial & Legal Intelligence

CHARGE of Fraud.—In Edinburgh Police Court on Friday last evidence was led before Bailie Dobie against Henry Archibald Spencer, photographer, 72, Princes Street, in connection with a charge of fraud. The charge was that on certain dates and at certain places he received from persons sums of money by false and fraudulent representation by pretending that photographs would be supplied for the money, he, it was alleged, not having intended to supply, and not having supplied, the photographs, whereby the persons were defrauded. Bailie Dobie, delivering judgment, said he had thought over the case carefully, and he felt the method of conducting the business had been so peculiar that he was not surprised that suspicion was aroused among those who had paid the money for photographs, and repeated promises of delivery of pictures—not fulfilled until recently, and in some cases not yet—bordered on what was almost direct misrepresentation, but he could not say that it had been proved that there was any intention of not delivering the photographs. He accordingly dismissed the complaint as not proven.

FAILURE of an Aberdare Photographer.—A meeting of the creditors of James Wildsmith Fyfe, photographer, carrying on business at 27, Cardiff Street, Aberdare, and residing at 37, Herbert Street in the same town, was held on Wednesday of last week at Merthyr. The debtor's statement of affairs showed:—Gross liabilities, £61 3s. 2d.; liabilities to rank for dividend, £143 15s. 6d.; net assets available for distribution, £54 4s. 1d.; deficiency, £89 11s. 5d. The following were the causes to which the debtor attributed his failure:—Losses sustained whilst trading as "The Welsh Fine Art Company" in partnership with another; having to leave his premises at Merthyr on the expiration of his lease; and bad trade.

At the Bromley Petty Sessions on Monday, Kenneth Martin and Malcolm Martin, brothers, the former described as a photographer giving an address at 9, Raglan Road, Bromley, were charged on remand with being concerned together in procuring charitable contributions by means of false and fraudulent pretences. Each prisoner was sentenced to one month's hard labour.

IMPROPER Photographs.—Chas. Flook, 27, and Thos. Evans 20, labourers, of South Woolwich, were charged with selling improper photographs at High Street, East Ham. The pictures sold to two detectives were shocking, and the prisoners said they were hard up and wanted to earn a crust. The detectives bought two of them and prisoners then went further down the street and accosted other passers-by. Prisoners now pleaded that they were out of work. Flook adding that his wife was very ill in bed, and he was forced to do this through poverty. One month each.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

July.	Name of Society.	Subject.
.....	Grickwood Photo. Society.....	Outing to Hatfield.
.....	South London Photo. Society.....	Trip to Penshurst for Chiddingstone.
.....	Hull Photographic Society.....	Outing to Hadison Hall
and 1	Everton Camera Club.....	Evening Outing to Kirkby Mill.
.....	Wallasey Amat. Photo. Soc.....	Members' Evening.
.....	Royal Photographic Society.....	Ordinary Meeting. Nomination and Election of Members only.
.....	Manchester Amat. Photo. Soc.	Outing to Llangollen.
.....	Hull Photographic Society.....	Outing to North Cave.

THE PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

MEETING of the General Committee was held at 51, Baker Street, W., on Friday, June 30. Present: Messrs. F. A. Bridge, Alfred Ellis, S. H. Fry, Wm. Grove, H. E. Hull, M. Jacobette, A. Mackie, Prodder, E. Scamell, and R. Fellows Willson. In the absence of the President, Mr. Alfred Ellis, Past President, in the chair. The rools of the assistants' certificates were examined, and passed after modifications.

Skeleton proofs of the "Circular" were passed round, and a discussion took place upon matters connected with its production. Several matters which cannot be reported were brought forward, and in order that the business ordinarily brought before the committee may not be impeded during the summer recess, when no committee meetings are held, the following members were appointed to act in cases requiring the decision of the committee: Messrs. Alfred Ellis, Ernest C. Elliott, William Grove, and Alexander Mackie.

THE Blackburn and District Photographic Society's new rooms at 41, Cross Street, were formally opened this week by Mr. A. Gow, B.A., Sec., Director of Education, and principal of the Blackburn Technical School. There is a well-lighted assembly-room on the first floor and a dark-room on the next floor. The former room was hung with an interesting collection of members' prints, including one or two London and provincial prize photographs.

LEITH AMATEUR PHOTOGRAPHIC ASSOCIATION has presented Mr. Murdoch Campbell with a marble clock on the occasion of his marriage. Mr. Campbell has been connected with the Association in an official capacity since its institution in 1888, and for the last eleven years has acted as hon. treasurer.

DUNEDIN PHOTOGRAPHIC SOCIETY.—The last meeting was the annual meeting of the society, and was held on April 13, when a fair number of members turned up. The president chosen for the year is Mr. W. W. Fenn; vice-presidents, Messrs. E. E. Stark and W. E. Allen; committee, J. Skottowe Webb, R. A. Ewing, E. J. Fenn, G. Crombie, P. Nelson, and A. A. Binnie; secretary and treasurer, J. Stuart White, Exchange Court, 98, Princes Street, Dunedin. It was decided that the Society procure a large size enlarging camera for official light, and Messrs. Fenn, Nelson, and Stark were appointed sub-committee to get a satisfactory article. The membership has increased during the year.

WARWICK Competitions.—The result of the June competition is as follows:—First prize, £10, Clarence Ponting, 12, Alma Square, Loughborough. Donation £5, to the Scarborough Photographic Society. Second prize, £5, A. G. Thistleton, 453, Oldham Road, Winton Heath, Manchester. Donation £2 10s., to the Manchester Amateur Photographic Society. Entries for the next competition must reach the Warwick Dry Plate Company, Warwick, not later than July 15 next.

Correspondence.

THE FREE ENLARGEMENT AGAIN.

To the Editors.

Gentlemen,—I enclose herewith, as I think it may be of interest to you and the profession in general, an advertisement from the "Daily Mail" of June 9 last, in reply to which I sent a photograph, and have just received the enclosed letter and coupon. The ignorant manner in which the letter is written and its brazen impudence, in such glaring contradiction to their advertisement, should, I think, be sufficient to open the eyes of the public.—Yours faithfully,

THE ELITE PORTRAIT CO., LTD.

E. J. Davis, Managing Director.

The following is the text of the advertisement and of the letter:—

In order to introduce into every family our artistic and beautiful works in crayon, the ATELIER PARISIEN DE PORTRAITS will make to all readers of this newspaper a LIFE-SIZE CRAYON PORTRAIT, splendidly finished, of 14½ by 20 inches, bust, of a perfect resemblance, ABSOLUTELY FREE, provided that the receiver of the portrait shows and recommends our works to relations and friends. Write your name and address plainly on the back of your photo, and send it to us by mail, together with this advertisement. NOTICE.—This offer is available for 20 days from date of this newspaper for the UNITED KINGDOM and for 60 days for the Colonies and foreign countries. WE DO NOT SELL FRAMES.—Address all communications to A. GRANVILLE (Manager).

M.—We have the pleasure to inform you that your life sized Portrait has been finished according to your instructions.

Owing to the skillfulness of our first class artists we are sure to send you an artistic work which will certainly meet with your approval. Its perfect likeness and its delicacy in execution renders it a work of art suitable for the most elegant drawing room.

In order to send it to you without any delay, kindly send us 5s. per postal order to cover our general expenses as well as those which we have to pay for the packing, carriage registration, etc. For the purpose of advertising our Portraits we willingly give our artistic work for nothing but it would be exorbitant to allow us to pay also those expenses considering the great quantities of orders which are sent to us, it would represent an enormous sacrifice.

As soon as we receive the 5s. we will send you the beautiful Portrait without any delay free of all expenses.

As already made known the value of the Portrait which we have done for you is 50s. But for you and your friends who should desire such an enlargement, we are willing for a certain time and always in accordance with the advertisement, to do the work for the limited price of 25s.

If you want to have your portrait mounted with a passport in a very elegant gilt or coloured frame, we can do this for 20s. and you receive the Picture complete free of expenses including postage and packing.

It is of course needless to mention that we will carry out your orders as you desire with or without frame. Trusting to hear from you by return mail,—We are, yours respectfully,

ATELIER PARISIEN DE PORTRAITS.

A. Granville, Manager.

N.B.—Please do not forget when you send us the postal order to

fill out and send us the enclosed coupon with the number corresponding with your Portrait.

Our rules do not permit us to send Portraits payment on delivery because the payments on delivery would only put our clients to more expenses and great formalities for us.

All communications to be addressed to Mr. Granville, Manager, 52, Rue Lafayette, Paris.

A GRIEVANCE.

To the Editors.

Gentlemen,—Would you allow me through your valuable medium to protest against a practice which is now being followed by many firms, viz., employing boys and girls to do work which should only be given to very competent men—I mean such as developing plates and amateur's films, printing same in Velox, etc.? It is not reasonable to expect a boy of 14 or 16, without previous experience, to take up this work and do it with justice to customers who send their developing and printing out. Yet this is what is being done in many firms, and when failures occur through careless handling the shopman is expected to tell some plausible tale to gloss it over.—Yours faithfully,

FAIR PLAY.

[Our correspondent must concede to a firm such as those he complains of the knowledge of how to conduct its business. Obviously, no firm is satisfied with a staff of incompetents, for the waste of materials would more than balance the advantage in wages. Possibly "Fair Play" does not appreciate the conditions which prevail in business of the kind he criticises.—Eds., B.J.P.]

A BUSINESS ASPECT OF THE COPYRIGHT QUESTION.

To the Editors.

Gentlemen,—The letter of Mr. Sutcliffe in your issue of June 23 raises an important question for the professional photographer.

When he finds his photographs reproduced by amateurs, by cheap firms, and as cheap enlargements or postcards at 3s. per dozen, your remark that "he has not much to complain of, seeing that he has been paid for what he has done," is but poor comfort.

Besides, is the idea conveyed in that statement quite correct?

In the past it has been the custom of photographers to spread the cost of producing first copies over the whole of the order, or prospective order. This first cost includes, necessarily, rent of studio, up-keep and interest on cost of cameras, lens, accessories, salary of operator, retoucher, and receptionist (chiefly). To cover this, prices have been fixed for the dozen and half-dozen. If smaller quantities are taken it is with the hope that the balance will be adjusted by further orders. In further proof that this is so I would draw attention to the great difference between the price charged for duplicate copies by the profession and the price charged for the same photographs by the trade printer.

This spreading of the cost did not much matter while the production of duplicate copies was almost entirely in the hands of the holders of the negative, and had the advantage of making the photographs singly appear cheaper to the general public. But the simplification and cheapening of printing processes during the last few years, and the more general knowledge by the public of the cost of producing a print, provides a strong temptation to the customer to get further copies at a much cheaper rate than the professional can supply duplicates for from the original negative. Here is the loophole for others to step in and rob the photographer of his legitimate profits, and here arises the feeling of injustice the photographer has when he finds his work reproduced apart from himself.

The tendency is for the further cheapening of reproduced copies; stationers and drapers are now entering the field, and amateurs have

probably long been copying the professionals' prints. The old-time monopoly of photographers for photographic prints has gone for ever, and a professional photographer's copyright in his own work seems unattainable. More and more the sale of duplicates is being taken out of his hands—the view trade is in the hands of stationers, the sale of prints of local celebrities has all but gone, the ordinary sitter alone is left, and that seems being undermined.

Where is the remedy?—Yours, etc.,

H. F. SMITH.

46, Stamford Hill, London, N., June 30, 1905.

[Comment is made on this subject under "Ex Cathedra."—Eds., B.J.P.]

"SITUATIONS WANTED."

To the Editors.

Gentlemen,—I notice a letter by "Disgusted," an operator retoucher out of a berth, who writes re his non-ability to secure the salary he thinks he is entitled to.

As the owner of two flourishing studios, one of which has to be under management, a few words on my experience may be useful to "Disgusted" and others like him.

I recently required a new operator-retoucher and general manager for a high-class branch in a fashionable town—and wished to obtain the best man that a good salary could command. From about thirty applicants I picked out what appeared to be the best man from his credentials, specimens, and salary asked. He came, he failed—absolutely—he left; and although that man knew, and admitted to me, that his work was "off," he applied for and obtained another berth in a distant town at an increased salary upon that which was paying him. Needless to say, I was horrified, and was also interested to follow his career, and found that, of course, he shortly left that post also, and I still frequently see his name crop up—he is still requiring a situation every few weeks.

After further experience I engaged a younger man of inexperienced but ability, with a wish to learn, at a moderate salary. The branch is flourishing, and so is its manager; but those like "Disgusted," who appear to quarrel with every photographer who does not consider him worth what he asks, are left out in the cold.

Why does not "Disgusted" ask himself this plain question? Is it not strange that every photographer who writes him refuses to pay him his wished-for salary?—Yours faithfully,

DISGUSTED No. 2.

June 28, 1905.

In consequence of special demands on our space this week, the continuation of the notes on retouching prints, together with several reviews of new materials, are held over.

PAINTER and Photographer.—On Sunday evening last, the Carlwright Hall, Bradford, was opened by the Art Committee of the Bradford Corporation for two interesting series of pictures. One is a collection of the paintings of the late William Stott, of Oldham, and the other is some representative examples of the photographic work of Alexander Keighley, of Keighley. The "Yorkshire Daily Observer," speaking appreciatively of Mr. Keighley's work, says: "In comparatively few years Mr. Keighley has sprung into the front rank of pictorial photographers, and he has had, indeed, no little influence in directing and guiding on right lines the efforts towards picture-making of scores of camera-workers in the country. Though keeping almost wholly to landscape work, he displays no little versatility of conception, and a ready appreciation for beauty of line and in tone. His power of securing even with the camera, which is apt to see and record too much, that quality of breadth, also apparent in all his works, especially in those of later date more than one of which is finely impressionistic."

Answers to Correspondents.

- * *All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C. Inattention to this ensures delay.*
- * *Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*
- * *Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.*
- * *For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.*

PHOTOGRAPHS REGISTERED:—

- H. Morgan, 28, Woodhead Road, Sheffield. *Photograph (Combination) Postcard containing Sheffield University (two views), Sheffield Coat of Arms, and the King and Queen.*
- Robert Plummer, 90, Queen Street (Maidenhead, Berks. *Three Photographs of His Majesty and Royal Party at Monkey Island, Bray, Berks, on June 24, 1905.*
- Augustus Lafosse, 12, Oxford Street, Manchester. *Five Photographs of Mr. F. Lister de Napleton I. No. 1. Empire. No. 2. Victory. No. 3. Moscow. No. 4. Waterloo. No. 5. St. Helena.*

- W. Rignall, 103, Fitzroy Street, Cambridge. *Three Photographs of the Bishop of Ely.*

URTON.—1. We know of no firm that would undertake to colour your cards. 2. You could certainly have them coloured at home, and you would probably find ordinary water colours as cheap as anything.

McCONCHIE.—We should think that Marion and Co., of Soho Square, W., would be able to supply you with what you want, or some such firm as Reeves, or Newman, the artists' colourman. Would not a Whatman paper suit you? These, we think, you would find free from spots.

OLD LEATHER BOTTLE.—There is an old leather bottle in our museum and a firm has made plaster models of same for sale in shops, etc. Can I copy this model and make similar ones for sale? Or, is it likely that it is registered, or copyrighted, or protected in any way—if such a thing is possible? This is the point on which I am wanting information.—BEAUCHAMP.

It is doubtful if the maker of the plaster models can establish copyright in his copy; the law of copyright in sculpture (which is what the modelling amounts to) is not clear on the point. Why do you not photograph the bottle, or obtain permission to have a second cast made? In either case you would be safe.

JOHN F. LESSELS.—We have forwarded your letter.

TOUCHING.—Your work is very poor and ragged, and entirely lacking in quality; but what can be expected when faces are

rushed over at this rate? One hour, or at least forty-five minutes, might be devoted to the reasonable treatment of such a negative. Its one good point is the preservation of the likeness, and many retouchers can easily lose it in five minutes. Work finer and blend your touching, instead of breaking off so frequently. Aim at solidity and softness of texture, and improve your modelling.

OLD PAINTING.—I have in my possession what seems to me to be a very old oil painting in good preservation; size of canvas, 25 in. by 20 in.; photograph of which I enclose. It is signed "Rubens" in red paint at the right-hand corner. Name is very distinct, the first letter thus (specimen enclosed) as near as possible. Can you give me any information as to its being a genuine Rubens, and an idea of value? I may say that I bought it at a sale in a very dirty condition for a small sum; also that I have been offered £5 for it. Any information about it will greatly oblige.—CANVAS.

It is impossible for us, or any one else, to say, from an indifferent photograph of it whether the picture is a genuine Rubens or not. We would advise you to submit it to some high-class picture-dealers, such as Messrs. Agnew and Sons, Old Bond Street. As to its value, if it be a genuine Rubens, it may possibly be worth some thousands of pounds.

IODISED PAPER.—I shall be glad if you will inform me what process was mostly favoured by the old school of photographers for preparing paper on which to make enlargements by projection before the advent of bromide paper and other such ready-made rapid papers, with quantities and manipulation?—FRED.

Iodised paper was what was used. The following is a good formula:—Iodide of potassium 120 grs., bromide of ammonium 30 grs., water 20 ozs. Sensitising solution: Silver nitrate 30 grs., and glacial acetic acid 30 minims, water 1 oz. After exposure the image was developed with a saturated solution of gallic acid, and fixed in hypo.

A SITTER'S RIGHT.—Can any one compel a photographer to remove photographs or enlargements from his window or show cases? I had a party who ordered an enlargement from a cabinet. She paid a small deposit, but I could not get the balance. I placed same in my window as a specimen, and she had the audacity to demand its removal. I think it would serve her right to attach a ticket, "To be paid for," or similar remark.—B. V. H.

She is perfectly within her rights. You have no right to use the negative, except at the sitter's orders. The fact that she has not paid does not alter the facts. You can sue her for the money.

COPYRIGHT.—I always read your replies re copyright laws with great interest, and, although they embrace a large variety of subjects, here is a point I do not think I have seen referred to. I have a copyright picture of a clergyman who died suddenly and I gave permission to the local paper to reproduce his portrait. I hear that an artist is painting his portrait, to hang in a public hall, from the one in the paper, in spite of its having the word "copyright" under it with my name as photographer. Now comes the question: Who ought to proceed against him—I, as the photographer of the original, or the proprietors of the journal; and ought they not to protect my rights seeing it is done from their paper? If you could find space to reply this week you would greatly oblige.—AN OLD READER FROM THE FIRST.

As the copyright is yours you are the one to take proceedings. The proprietors of the paper are not the owners of the copyright in the portrait, so they can take no action. You are the only one who can.

RESIDUES.—1. I have about three large sacks of gelatine P.O.P. cuttings. Please say if they are of any value, and if it will pay me to burn them to ashes and send residue to an assayer? 2. Is it worth collecting the old fixing baths and taking the silver out of them also?—**INQUIRER.**

1. If the paper has not been fixed we should think, as there is so much of it, it would be worth your while to do as you suggest. You must bear in mind, however, that the silver, when recovered, is only worth about 2s. 3d. per oz.—supposing it is of the standard purity. 2. Yes, if you work on a tolerably large scale.

A DOUBTFUL CLAIM.—Some time ago a photographer, within a few minutes of me, sent for me and asked me if I would hold myself in readiness to go to him to do his operator's work if he sent for me, his operator going away for a week's holiday. I agreed to do so, and remained indoors, at his request, for a week. That was some months ago, and I have not yet received so much as a postcard of thanks. Can I legally claim something in the way of remuneration? Nothing was mentioned to that effect.—**SHADOW CATCHER**

Unless there was some agreement to the effect that you were to receive remuneration for holding yourself in readiness we fear you can recover nothing, as your services were not required after all.

VOLTA.—The Bastian Mercury Vapour Lamp, Limited, Bartholomew Works, Kentish Town, London, N.W.

CLEANING OLD NEGATIVES.—Will you please let me know the best way for cleaning off negative films, principally gelatine. An offer has been made for a lot of 15 by 12 and 12 by 10 for hothouse glazing purposes, but they must be without films. There is an available wash boiler. Would soda or acid help without injury to hands?—**R. K.**

A hot solution of caustic soda will soften the film, so that a stroke of a stiff scrubbing brush will remove the film at once from each. But a better plan is, let the plates soak for some hours in hydrochloric acid (spirits of salts) mixed with about ten times its bulk of water. But the acid must not be used in an iron vessel, and whichever is used the hands should not be kept in the liquid longer than necessary.

BOOKS.—I should esteem it a great favour if you could tell me the best books on the following two subjects: (1) "Studio Lighting and Posing," (2) "Retouching"?—**P. W.**

1. "Lighting in Photographic Studios," by P. C. Duchochois, 1s.; "Artistic Lighting," by James Inglis, 2s. 6d.; and the "Pose in Portraiture" (No. 1 of the "Photo-Miniature"), 6d. 2. "The Art of Retouching Negatives," by Robert Johnson, 2s.; and "Retouching," by Arthur Whiting, 1s.

RETOUCHING ("T.P.").—Your retouching is very indifferent, and not at all up to first-class professional requirements. No. 1 is dirty in the working, and the men have no texture. Your knowledge of modelling is very limited. Try for a better grain; increase your high lights, and get rid of the general raggedness. 2. Your salary, we consider, would be governed more by your abilities as operator and receptionist than by your retouching (in which you require further lessons), and we consider that you might expect from 30s. to 35s. per week.

SALARIES OF ENLARGERS.—I am writing to inquire if you can advise me as to the salary usually paid to enlargers. I have been doing enlarging now for two years, for a leading West End firm, and I am paid 38s. per week. I am doing the very best class work, and I think I am underpaid, as I hear some

enlargers obtain as much as £4 per week. Would you kindly advise me.—**ZENO.**

Of course salaries depend very much on ability. We should say that what you are paid is about the average sum, and no above it. We think that there are very few enlargers paid as much as £4 a week at the present time, that is, if they enlarge only on bromide paper. For making enlarged negatives a larger salary would be paid.

PHOTOGRAPHY IN WEST INDIES.—I should be very much obliged if you could give me some information about photographing in the West Indies. 1. Is it unwise to take an expensive camera on account of the climate, and what precautions can one take to prevent its being damaged by mildew or insects? 2. Are plates or films the most satisfactory to use there? 3. What is about the exposure required compared with what one usually gives during one's summer holiday in England?—**WEST INDIES.**

1. The better the apparatus is the better will it withstand adverse climatic conditions. The only thing to do is to protect it as much as possible from damp and insects. 2. We should ourselves prefer plates. 3. We should imagine about the same or perhaps a little less: in consequence of the dark shadows cast by the brilliant light, the common error is to give insufficient exposure.

AMERICAN SIZES.—I am thinking of settling in the United States of America very soon as a photographer. I possess a good 12 by 10 outfit, also whole plate. I want to know what size camera and plates are in general use over there, and whether the above would be of service to me; or would it be advisable to dispose of same before leaving.—**H. L.**

Twelve by ten is a common size in America, and so, to a lesser extent, is 8½ by 6½. You will have no difficulty in getting plates of these sizes.

CHROMATIC.—The Vanguard Manufacturing Company's "Bertha" colours, or "Revoli's" magic photo tints, sold by Marion, of Soho Square, will be suitable for the purpose you mention.

THE Northern Photographic Exhibition and the Lay Press.—The good people of Leeds will be gratified to learn from the "Yorkshire Evening Post," that "the striking developments which have revolutionised the photographic world since an image on a sensitive plate was obtained by the use of the cigar-box and the spectacle lens are abundantly illustrated at the Northern Photographic Exhibition at the Leeds Municipal Art Gallery"; and also that, in addition to the list of local exhibitors given in the same organ, "there are many others, not local, who have the addresses of such distant places as London, and even Scotland." The Metropolis is getting quite well known, it seems.

**** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

EX CATHEDRA.

Under the presidency of Professor J. Joly, the twentieth meeting of the Photographic Convention of the United Kingdom was inaugurated in Dublin, on Monday last, under climatic conditions which leave no doubt that, photographically, the week in and around the Irish capital has been a profitable one. Numerically the Convention is, perhaps, somewhat less than in previous years; but in its character and universal disposition to contribute to the common enjoyment, it fully sustains the reputation of its recent predecessors. Dr. Joly's address, which we print on another page, touches an aspect of photographic theory which we have recently drawn attention at some length to on these pages; and it, with the paper of Mr. Thorne, is to be read to-day, constitutes the whole literary or scientific *acta* of the Convention. Officially, that is. For it cannot be conceived that three hundred or more photographers attending a week in one another's company will not discuss everything and anything bearing on their own special photographic proclivities. This inherent feature of the convention, occasionally forgotten by certain critics, constitutes, perhaps, its most important *raison d'être*. While we are strongly of the view that the "paper" programme of the Convention cannot be neglected except at the risk of the future prosperity of the body we do not underrate the difficulty of obtaining papers to be read, and people to attend to them. And we also realise—and would here press the facts on every photographer—that the Convention provides conditions in the highest degree propitious to the interchange of ideas and the mutual benefit of its members. The good work which it accomplishes in

this way is none the less actual and valuable because it does not admit of an itemised report; but it is the magnet which draws Conventioners year after year to the venue of the meeting.

* * *

The 1906 Convention. All members of the Photographic Convention will receive with pleasure the announcement that next year's meeting will be on the South Coast of England. An inspection of the list of places visited during the past nineteen years discloses the fact that with the exception of the Plymouth Convention of 1893, no place south of the Thames has been made the centre of this annual gathering. Southampton is the chosen locality for the 1906 Convention and a better centre could not be desired. With the beauties of the Isle of Wight, and the New Forest, Winchester Cathedral, Netley Abbey, and other notable attractions close at hand, to say nothing of the Solent and adjacent Portsmouth, photography of a type quite unlike anything obtainable at previous Conventions will be possible. There is also no doubt that the Southampton Camera Club, from whom the invitation comes, will manage the local arrangements satisfactorily, and, given fine summer weather like the present, the 1906 meeting should be a popular one.

* * *

The Ilford Competition. Ilford, Limited, must have every reason to be satisfied with the result of their recent £750 cash prize competition. The exact number of entries has not been disclosed, but we understand they were very great, and the judges must have found the sum of money at their disposal all too small to apportion amongst so many, notwithstanding that extra prizes were added to the original amount. An interesting exhibition of photographs by the prize winners was opened at the Modern Gallery, 61, New Bond Street, London, W., on Saturday last and remains open until 6.0 p.m. this evening (Friday). Works from all parts of the world are on view, and amply demonstrate the far-reaching extent of the firm's output. The plan adopted in this exhibition, of which a report appears on another page, is somewhat peculiar, but will doubtless have the effect desired by its organisers. The exhibitors' names are not given on the pictures, neither is there a catalogue or other indication of the titles or specific awards published. The pictures are, therefore, shown simply on their own merits, and their face value can be taken as indicative of the application of Ilford materials. In view of the fact that many of the prize winners wished their names withheld, this is probably the wisest course that could have been adopted, and

the bulk of the pictures will, therefore, have greater opportunities of appealing to the visitors as straightforward photographic productions unembarrassed by this or the other well known name being attached.

The Action of Wood on Photographic Plates.

About a year ago Dr. W. J. Russell detailed some experiments as to the action of certain woods on dry plates (B.J., August 19, 1904, p. 726), and suggested that probably this action should be ascribed to hydrogen peroxide. A correspondent to our contemporary "Knowledge" states that, believing that the action was due to radioactivity, he used a very sensitive screen and distinctly observed from a piece of white fretwood the scintillations which were about as bright as from uranium, pitchblende, or radium, the great difference being, however, that, whereas with these substances the emanations are poured forth in such numbers as to cause an almost continuous lighting up of the screen, in the case of wood they only came singly or in twos or threes, with a considerable interval between each. This would naturally account for the somewhat feeble photographic action of wood, as it would be necessary for considerable time to elapse before sufficient effect had accumulated to produce a latent image.

The Camera Club Company, Limited.

The future prospects of the Camera Club do not at present look particularly rosy. As we hinted a short time ago when the directors' report for 1904 was published, the lack of *esprit de corps* and other factors making for the success of an institution of this character were conspicuous by their absence. We now see that an extraordinary general meeting is called for Monday next, July 17, to discuss the unsatisfactory financial condition of the club, and to decide as to the means to be adopted with a view to the continuance of its existence. About £300 will be necessary to carry on the concern to the end of the year, and five courses are suggested for adoption. They are: (1) To make a whip, and invite subscriptions for Preference shares; (2) To make a whip, and increase the amount of subscriptions for the year 1906, and possibly subsequent years; (3) To amalgamate with another club; (4) To give up the present premises and take smaller ones, becoming a small photographic society with suitably reduced subscriptions; (5) To wind up the company and close the club altogether. We look forward to the result of this meeting with great interest. It certainly seems a great pity that an institution with the prestige of the London Camera Club should be in such dire straits. We doubt whether the members will rise to the demands made by suggestion 2, as the present subscription is generally considered quite sufficient for the value offered; while 3, 4, 5, mean the total extinction of the club. The first proposal, therefore, seems the only one that is likely to maintain the present premises in Charing Cross Road, and we trust that with complete reorganisation and better management the past achievements and reputation of the club may be revived, and its present sorry condition made a thing of the past.

Miniatures. The "Daily Mail" recently published a letter in its correspondence column from an artist, denouncing the sale of pictures ostensibly "miniatures," but really "coloured photographs." We should be the last to support photographers in any wrong description, but we may well ask whether artists have any prescriptive right to the use of the word *miniature*. A miniature may be a small photograph or picture of any description, either in monochrome or otherwise. The probability is the customer

who bought the picture in question paid so small a price that good painting and drawing on the ivory alone were out of the question. It is usually those who have beaten down prices who complain most when they find quality has correspondingly fallen. The writer of the letter, too, who signed with a pseudonym, is complaining because the inevitable and universal progression and competition are making it more difficult for him to earn an income on the old lines. Except to the very few at the top of the profession, all artistic work yields a very poor return in £ s. d., and it is only by the severe application of ordinary commercial methods that profitable results accrue. Not only does this apply to photography, but to the many branches of artistic work which photography has attacked.

A Hint for the R.P.S. Affiliation.

The new edition of the "Blue Book" issued by the Scottish Photographic Federation, and analogous to the "Red Book" of the R.P.S. Affiliation, contains two excellent ideas that can be commended to the notice of the executive of the latter in view of the increasing desire to further cement the units of which it is composed. A number of gentlemen prominent in Scottish photographic circles have kindly agreed to advise members of the Federation on various photographic subjects. The list of twenty-five sections given embraces almost every possible subject in photography on which advice can be sought. From "apparatus" and camera construction, optics and chemistry nearly every process and application of photography to "mounting and framing" is considered, and experts appointed. This expert advice is given free, and return postage for specimens is the only condition imposed. That a lot of work is created for these willing helpers is not likely to be the case, as a number of names appear under each section. Thus, for instance, under "Lantern Slides" no less than nine well-known names in Scottish photography appear, and the addresses are in various centres. The gazetteer is likewise worthy of note. The names, addresses, and officers of the federated Societies have been compressed into the smallest possible compass consistent with effective display, and the space thus gained has been devoted to a particularly interesting gazetteer of photographic interest. An up-to-date list of dark rooms is given which may be made free use of on presentation of the "Blue Book"—a most important concession—and, moreover, "local reporters" have been appointed in each of the towns and districts mentioned. These gentlemen will send full information about the districts they represent, on receiving a request, accompanied by a stamped addressed envelope. This breathes the true spirit of practical co-operation, the utility of which cannot fail to be of the utmost value to the federation, and is worthy of imitation by all other similar organisations.

The Portrait Lens.

Twenty years ago the Petzval form of portrait lens was seen in practically every studio. Nowadays it is being practically displaced by rapid rectilinears or the more modern lenses whose freedom from astigmatism enables them to be employed at greater apertures. Nearly ten years ago we knew of a North-country professional who constantly used rapid applanats at $f/6$ even for child-portraiture, and we believe one of the best-known London professionals uses a comparatively cheap French R.R. for almost the whole of his work. Plates are now quick enough to admit of less rapid lenses being used, but in point of fact the anastigmat at $f/5.6$ is practically as rapid as the majority of Petzval lenses marked $f/4$, for in many such instruments if the aperture be accurately measured it will be found to be something less than $f/4$. The necessity for

a portrait lens is one of the traditions of old-fashioned photography which dies hard, but in time, when it is recognised that the modern form of lens may be used both indoors and out-of-doors, and is perfectly efficient for portraiture, it will probably almost completely displace the Petzval form.

* * *

Lenses for landscape. The mention just made of the double use to which $f/5.6$ anastigmats may be put applies principally to group work out-of-doors. The figures are arranged approximately in one plane and marginal definition is as good as that in the centre of the field at full aperture. Thoughtful lens users know by now that the almost perfect corrections for astigmatism and curvature of field do not in any way increase the depth of definition, and that the cheap R.R. needs no more stopping down for this end than the best of the anastigmats. Hence, when on a large plate, say, 15 by 12, both near and distant objects, as in landscape work, are to be focussed sharply, the performance of the R.R. is equal to that of the anastigmats. This point is often lost sight of by inexperienced workers who are purchasing lenses. If the lens is likely to be always employed at such stops as $f/22$ or $f/32$, then the R.R. will give as good results as an anastigmat. On the other hand, if group work and portraiture are required, it will pay to have the flat-field lens. Another branch of work in which a lens giving a flat field and fine marginal definition is of immense value is the copying of maps and pictures on orthochromatic plates and using light filters. Sharpness over the entire field can be secured at open aperture, and, though the difference between one second exposure at $f/6$ and 28 seconds at $f/32$ is not of importance, yet when these times are multiplied by forty for the light filter the saving of time accruing from the use of the better corrected lens is of material importance.

* * *

The Poisons Bill. A deputation from the Pharmaceutical Society visited the President of the Board of Agriculture at the House of Commons last week in reference to the sale of poisons for agricultural and horticultural purposes. Mr. Fellowes's reply to the deputation will be of considerable interest to photographers and others who make use of quantities of certain scheduled poisons. He stated that an enormous number of resolutions had reached his Department from bodies all over the country in favour of a relaxation of the present law. But the question of the public safety was one of immense importance, and neither his Department nor Lord Londonderry, as head of the Privy Council, would ever do anything that would occasion the slightest risk to the general public in connection with the sale of these compounds. Some of the regulations to be made under the proposed Bill would provide:—1. That no poisonous substance shall be kept in any shop or premises where articles of food are stored or kept for sale. 2. All poisons must be kept in a cupboard separate from other goods. 3. All poisons shall be sold in an enclosed vessel labelled with the word "Poison." 4. Liquid poisons shall be sold only in bottles or tins easily distinguishable by touch from ordinary bottles or tins. 5. In granting licences, the local authority shall have regard to the facilities already existing in the neighbourhood for the purchase of poisonous compounds.

* * *

To Cinematographers. It is a commonplace now that it is the new idea that pays. How much money has been made by the application of new ideas to cinematography is perhaps scarcely realised. We have been wondering why the cinematograph is not applied

to many of the changes which are constantly occurring in the metropolis, serving two purposes—an interesting film for exhibition and a permanent record of an historic change. To take as an example, the pulling down of St. James's Hall and the contiguous buildings in Regent-street and Piccadilly, and the erection of the new Piccadilly Hotel which is to be put up on the site. Why should not a series of photographs be taken at suitable intervals showing the periodical demolition of the old and the growth of the news? Certain difficulties would occur, and the exposures would need to be made with care and from a fixed standpoint, and of course the apparatus would be kept on the one piece of work for a long time. It may be that such a film would not be sensational enough or humorous enough for the British public, and that is a matter on which the large film-producing firms are the best judges, but, as a record of modern building methods, this extended series of "progress photographs" would be distinctly interesting.

PRINTING PROCESSES.—VII.

P.O.P.

PLATINUM toning is generally used for matt surface papers, and various tones ranging from cold sepia to brownish black can be obtained by varying the time of toning and also the composition of the bath.

The depth of printing for platinum toning depends to some extent on the bath that is used, but as a rule it should be a little deeper than for gold toning. There are one or two main lines of treatment to which all prints, whether gelatine or collodion, should be submitted, if evenness of tone and purity of the whites are to be obtained.

In the first place the most important point is the conversion of the whole of the silver salts into chloride, for as has already been pointed out, the emulsion usually contains organic salts of silver and free organic acid. If these are left in the film, it is difficult to avoid slight tingeing of the whites, nor can the tone as a rule be carried to the rich deep brownish blacks. To get rid of these salts is a simple matter, as the prints merely require immersing for five minutes in a solution of salt, as recommended prior to gold toning, and whilst it is purely a matter of choice for gold, it is essential before platinum toning. It is advisable also to thoroughly wash the prints after the salt bath.

The platinum salt generally used for toning is the chloroplatinite of potassium, and this only tones satisfactorily in an acid bath. Within reason, it is immaterial with what the bath is acidified—it may be either an organic or mineral acid or an acid salt. If the latter be used, the bath acts slowly; with an organic or phosphoric acid the action is quicker, and most rapid with nitric or hydrochloric acid; though with the latter acids yellowness of the whites is a frequent trouble. The simplest of all baths, and which, so far as we have found, acts satisfactorily with every commercial brand of paper, is that acidified with phosphoric acid. Rapidity of toning is dependent not only on the strength of the chloroplatinite, but also on the temperature of the bath, and this is important. We have frequently found that certain makes of paper which did not tone satisfactorily with platinum gave quite satisfactory results as soon as the temperature of the bath was raised to about 65 deg. to 70 deg. Fahr.

The quantity of platinum salt may vary within wide limits, from 0.2 to 5 grains per ounce of the bath, but a good working bath which works quickly, and which will give any tone from sepia to brownish blacks, is one con-

taining 1 grain of chloroplatinite per ounce. A suitable formula will then be:—

Chloroplatinite of potash	10 grs.
Dilute phosphoric acid	$\frac{1}{2}$ oz.
Distilled water to	10 oz.

Dilute phosphoric acid may be obtained from any chemist or dealer, or if thought more convenient the concentrated acid may be obtained, and then only one-sixth of the above quantity should be used.

It is a little difficult to determine the exact tone obtainable whilst the print is in the bath, as the final colour is only seen when the print is fixed or dry; but a very few trials will determine the necessary duration of toning to obtain any desired colour.

It is important that the print after toning be freed from all traces of the platinum salt and acid; for the latter will decompose the hypo and cause the well known sulphuration which is not conducive to the stability of the print. If the platinum salt is not removed also, it combines with the hypo, and the salt formed is extremely insoluble, and a general tinge may be the result. It is advisable, therefore, to thoroughly wash the prints after the toning bath; this may be facilitated by immersing them in salt and water, and finally passing them into a weak carbonate of soda bath, or the soda may be added to the fixing bath.

With very deep printing, a toning bath rich in platinum and at a temperature of about 65 deg. to 70 deg. Fahr., as recommended, warm blacks are easily obtained; but for pure blacks verging on the cold side, it is advisable to first treat the prints to a gold toning bath, and preferably an acetate or borax bath in which they should be left till they have assumed a reddish violet tinge on the surface; they must be well washed, and then treated to the above-named platinum bath.

For pure black tones on matt surface paper, particu-

larly on collodio-chloride paper, the following bath is very satisfactory:—

Potassium chloroplatinite	5 grs.
Meta-phenyldiamine	5 grs.
Distilled water	10 oz.

The prints must be washed in plain water before using this bath, and also well washed after toning.

The well known red tone, commonly known as Bartolozzi red, can be best obtained on matt surface papers, for which alone it is suitable by treating the prints to a salt bath, then well washing and toning in:—

Uranium nitrate	10 grs.
Thiosinamine	50 grs.
Distilled water	10 oz.

The prints must be well washed after this and before toning.

Carmin red tones are obtainable on some papers only, by the following bath, which was recommended first by the late M. Helain. Why it should fail with some and succeed with other papers we are unable to say; it is also very slow in action, this being increased with the reduction of the iodide:—

Ammonium Sulphocyanide	25 grs.
Potassium iodide	$2\frac{1}{2}$ grs.
Chloride of gold	$1\frac{1}{2}$ grs.
Distilled water	10 oz.

Fixation takes somewhat longer after this bath than usual.

There is not much that is novel to be said about platinum toning, but as with care and reasonable precautions it gives a series of tones, which are quite distinct from those obtained with gold, it affords a welcome change, and is likely to lead to business from a professional point of view. It has been advanced as against the use of platinum that prints are not so stable as with gold toning, but this cannot be substantiated, and if spots and stains occur, it is more likely to be due to the non-observance of the simple precautions we have pointed out.

SENDING PHOTOGRAPHS BY TELEGRAPH.

II.

[Last week the general principles of electric transmission of pictures and the Korn system were described and discussed.—Eps. B.J.P.]

The Receiving Apparatus.

At the receiving station we have again the revolving cylinder, which, however, is only a quarter the size of the transmitting cylinder, and is made of ebonite. It will thus be seen that the reproduction is reduced in the proportion of 1-4. Immediately above this receiving-cylinder, and at a distance of only 1 or 2 m/m. from it, is fixed the little Geissler tube, which is shown in Figure 3 in about actual size. It consists of a glass tube, containing two wires (A1 and A2), between the ends of which (SS) the luminous discharges passes. The tube is encased in a thick ebonite cylinder, and the top is covered with sealing-wax. The only light which can issue from this tube comes from a small aperture (B) measuring $\frac{1}{4}$ m/m. as above-mentioned.

The Mechanism of the Receiver.

Figure 4 shows diagrammatically the actual receiving portion. It consists of a so-called "moving-coil" system, which is a small frame (C) wound with very fine wire, and suspended between the poles (S and N) of a powerful horse-shoe magnet. This frame is kept in a certain neutral position by the two hair-springs (LL), through which the current from the line enters. The axle of the frame is carried in jewelled bearings, and it carries a very

light glass tube of about $\frac{1}{2}$ m/m. diameter, at the ends of which two fine copper wires (P1 and P2) of about $\frac{1}{4}$ m/m. diameter and

Fig. 4.

20 m/m. length are fixed. Instead of altering the spark-gap as in the old arrangement Professor Korn now uses a number of electric

stances (R I., R II., R III., R IV.), which are connected to collecting points, between which the copper points (P 1 and P 2) play without friction; and a glance at Figure 4 will show that, according to the position of these points, the high-potential current generated in the coil T, and carried to the tube, will be more or

so that we may either weaken or strengthen the current through the tube for a given variation in the original, and so produce at the receiving station either a positive or a negative film, a by no means unimportant feature of Korn's method.

The high-potential, or "Tesla," current which flows through

Fig. 5.—The Sending Apparatus by which Drawings and Music were Telegraphed from Paris to Rouen (see p. 526).

For the photograph of this and the receiving apparatus (fig. 6) the Editors are indebted to the "World's Work," which gives a popular account of Professor Korn's invention in its July issue.

Fig. 6—Professor Korn's Receiving Apparatus (see p. 526).

ss weakened, according as to whether it has to pass through a eater or lesser portion of these four resistances. It will also seen that by simply changing the direction of the incoming rrent (from the transmitting station) the frame C can be made turn either in one or the other direction for a given impulse,

the resistances and the tube, is produced either by means of an induction-coil and a "Tesla" transformer (D), or it may be d. ived from the motor driving the receiving-cylinder after suit- ab. transformation. The advantage of these currents is that, in s. 'te of their high-potential, they are perfectly harmless, when

accidentally taken by the operator, and, being of an oscillating character, they are not likely to impede the movements of the points (P 1 and P 2) as would be the case were one to use static electricity. Of course, this sensitive galvanometer, as well as the receiving-cylinder, are properly boxed and protected against mechanical vibration. In Figure 6 the galvanometer is numbered 4, the receiving-cylinder 7, and the induction-coil 6.

Practical Limitations.

These are, in short, the essential parts of an installation, although, as above-mentioned, many delicate electrical controlling devices are in practice indispensable. The limitations of the method are due to:—

1. The inertia of the selenium cells, which makes it impossible for them to follow accurately very rapid and slight variations in the illumination.

2. The inertia of the moving part of the galvanometer; but so much progress has been made in this direction that it is possible to transmit an original measuring 12 by 18 m/m. within twenty-four minutes, and by a slight mechanical improvement even within twelve minutes.

The distances over which these extremely minute variations in the current can be transmitted is astonishing, and these are only limited by what is electrically termed the capacity of the line. There is no doubt that a good deal remains to be done before the system, as above described, may be pronounced commercially perfect; but the progress made, even within the short interval of three years, and the energy of the inventor, give promise of an early perfection of the method, and of a greater speed in the working of this system.

The realisation of the problem of seeing distant things electrically is, of course, a totally different and vastly more difficult matter; but, as Professor Korn has pointed out, it must be preceded by a reliable system of electrically transmitting pictures and may possibly be evolved from it, when experience has shown us how to reduce the time factor in transmission. To my thinking, however, something more is required—a substitute or vast improvement of the selenium cell, sensitive to all parts of the spectrum, and rapidly recovering. A promising field of research is here open to the investigator, full of practical photographic interest.

A. W. ISENTHAL.

THE BREAKAGE OF NEGATIVES: HOW TO PREVENT IT.

THE cracking or breakage of a valuable negative is an exceedingly mortifying occurrence. Sometimes, with the expenditure of much care and trouble, the film may be stripped and transferred to another glass, but in a large percentage of cases the film also is broken, and perhaps irremediably ruined. In any event, prevention is undoubtedly better than cure, so that some little study of the various ways in which such mishaps take place, and the methods by which they may be anticipated and avoided, recommends itself as good policy.

Dangers Before Exposure.

To begin at the beginning, although, strictly speaking, an unexposed plate is not a negative. It is by no means unusual, through careless handling or dropping of the boxes containing unexposed plates, for one of these to be slightly cracked. The obvious remedy is to examine carefully each plate when filling the slides, and to reject any which show any sign of a crack. Mischievous often happens through particles of grit getting in the dark slide rebates; these should be inspected at intervals and dusted out if necessary. Occasionally, a plate may be a trifle over the usual size, and fit too tightly in the slide, possibly requiring a little force to insert it. On no account should such a plate be used for an important subject, for a crack may be started in some manner or other before the plate comes out of the slide. It should be seen that the dark slide springs are not too powerful, and all unnecessary concussions or shakings should be avoided, especially with large plates. On this account, it is advisable to compel the shutters to work easily, if they do not already do so, by rubbing the grooves with a very small quantity of powdered blacklead.

Two Dark Room Precautions.

Coming in due course to the developing operations, it is wise to use deep dishes, since the negatives clearly cannot so easily slip or be dropped out by any accident. Also, such dishes are heavier and not so liable to mishaps. A lead-lined sink with a wooden grid is decidedly best when a negative perversely slips from the fingers; there is at least a sporting chance it will not be broken, whereas, if the sink is of stone-ware, the result is almost a moral certainty in the other direction. Similarly, a wooden floor is to be preferred to a stone one.

When Washing and Drying the Negative

the grooves of the washing tank should be neither too tight nor too loose, and the flow of water must not be heavy or

violent. A word may be said on the subject of draining racks, viz., that the folding variety have an unpleasant knack of unexpectedly shutting up while being moved with negatives in them, thus frequently causing an alarming spill. The best way to prevent this is to make the rack incapable of folding by driving in a short nail or adopting other suitable means. The rack should be large enough and should have a sufficient extent of grooving in contact with the edges of the negatives, so that it becomes impossible for the latter to shift and fall through any sudden shake or puff of wind. To attempt, for example, to dry a 12 by 10 negative in a quarter-plate rack is simply courting disaster; even in the case of a half-plate one it is at least risky. It seems almost unnecessary to warn the photographer never to stand negatives outside the house in a strong wind.

A Safeguard when Retouching.

The next thing to be considered is the retouching desk. This should be furnished with some satisfactory means of fixing the negative, so that it cannot slip or fall while working, or when the retoucher is temporarily obliged to leave it. The professional photographer knows only too well how many negatives are lost through the omission of this simple precaution. It is not sufficient to have merely a ledge on which the negative rests, or a rebate for it to lie in; there must be some provision for gripping or holding it so that it cannot slip sideways or fall forward. There are various patterns of retouching desks on the market in which this requirement is met, or, if such an arrangement is lacking, a good plan is to glue a thin, flat sheet of cork over the front of the desk, first cutting out a suitable opening, and to fix the negative in any required position with fairly large drawing pins. The cork facing will last some time without renewal. A desk having a rebated opening should be provided with buttons or catches at the sides of the latter, and these should not be allowed to become so loose as to be useless. Care must be taken that the front of the desk is perfectly flat and free from grit or projections.

Printing Frames and Breakages.

The largest number of breakages, however, are apt to occur during the printing operations. A good many may be attributed to uneven rebates in the printing frames, although much more care is now taken by the manufacturers to avoid this defect than at one time. Before any printing frame is used, the rebate should be critically tested by means of a

perfectly flat piece of glass, the size of the negative. This should be laid in the rebate, first one way and then the other, trying also both sides, and pressing with a finger round the edges of the glass to see if there is the slightest shake or departure from a true level. If such is found, the uneven surface may be reduced to its proper depth by means of a pen-knife and glasspaper. It should also be ascertained that the curved back of the frame exerts an even pressure and is level inside. The springs, if too strong, should be bent until the pressure is considered just sufficient. All printing frames should be tested from time to time, since exposure to damp and variations of temperature will often serve to warp them and render them untrue.

When Vignetting.

Occasionally, breakages may be traced to the points of tacks used in fastening vignettes coming through the thinnest part of the frame and projecting inside the rebate, or, even if they do not actually project, causing a bump or prominence. To avoid this, all tacks should be driven in near the edges of the frame. It is distinctly an advantage if the back and springs of the frame do not project when closed, for the following reason: It is customary when the frames are not printing, or during refilling, to stack them in a pile, and a little reflection will show that, if the back or springs project, the whole weight of the uppermost frames is pressing on the negatives contained in those at the bottom, whereas, if there are no projections, the stress is borne by the sides of the frames, and does not

reach the negatives at all. An ingenious and simple method of overcoming the former disadvantage is to fix small circular bosses of rubber at the back of the frames. The backing material used in filling in must be evenly distributed and free from lumps or grit.

Safety in the Post—How to Pack a Negative.

Probably little need be said as regards the storage of negatives, for, if properly grooved boxes are employed, an accident can only be due to carelessness. The transmission of negatives by post need not cause any anxiety if the screw-down boxes now obtainable, with circular felt pads between which the negative is laid, are used. The only safe alternative to these is the employment of a thick and solid wooden box, larger each way than the negative, so as to allow of a liberal amount of loose packing (such as shavings or wads of tissue paper) being evenly and tightly distributed on both sides and round the edges of the latter. Care should be taken that the bottom layer on which the negative is laid, enclosed in a suitable envelope, is level and free from any hard substance. In conclusion, a most useful hint may be given to users of box-form hand cameras in which the plates are caused to fall into a lower chamber when changing—which is, simply to glue a piece of thick red or black felt over the bottom of the receptacle into which the plates drop. It is true that a breakage does not often occur even without this precaution, but with it the chances of mishap are reduced to a minimum.

A. LOCKETT.

THE WEEK IN HISTORY.

The First Gelatine Dry Plate.

IN THE BRITISH JOURNAL OF PHOTOGRAPHY for July 18, 1873, appeared the first advertisement of a gelatine emulsion. I reproduce it herewith. It will be noticed that the preparation

instance of how progress seemed to turn on its natural course, I quote from THE BRITISH JOURNAL OF PHOTOGRAPHY of July 14, 1871, the hopes entertained of emulsion to be applied by the photographer himself. Thomas Sutton, after reviewing the

ii

THE BRITISH JOURNAL OF PHOTOGRAPHY.

[July 18 1873]

MR. J. BURGESS

Begs to announce that, as the result of innumerable experiments, he has made an

IMPORTANT PHOTOGRAPHIC DISCOVERY,

which enables him to Prepare Dry Plates equal in Sensitiveness, and superior in many respects, to the best Wet Plates, and that simply by pouring an Emulsion (prepared by an entirely new and original method) on the glass and allowing it to dry without any washing or the application of any preservative, thus saving an immense amount of trouble and expense, and what is more important, still securing films of absolute uniformity, of good keeping qualities, and up to the highest standard of excellence.

In order that anyone may test the truth of the above statement a Four-ounce Bottle of the Emulsion, sufficient to coat Four or Five Dozens Quarter-Plates, will be sent, post free, for 3s.; and, when the new method has been thoroughly tested, if 500 Subscribers are willing to pay One Guinea each, a pamphlet will be printed giving an account of the experiments which have been tried, and the formula by which the results above described have been realised.—Address, Mr. J. BURGESS, Artist, 207, Queen's Road, Peckham, S.E.

not described as of gelatine, although the behaviour of the emulsion could not leave this matter long in doubt. The formula employed by Mr. Burgess never became public, and the emulsion itself gradually dropped out of the market.

The Process of the Future—in 1871.

The stream of progress in any art or science is often a curiously crooked one. It doubles on its course, and until long afterwards it is difficult to recognise in these reversed currents the same confluence which flows constantly from one source. Thus have referred to the early efforts to replace wet collodion by dry plates, and have also noted the slowness with which the ready-made emulsion dry-plate came into vogue. As an

state of knowledge at that time, exclaims:—"A tourist . . . would have his bromide of silver emulsion ready made in a semi-solid state resembling blanc-mange; he would melt it by putting the bottle containing it into boiling water; he would then coat his plates at night for the next day, and put them at once into the plate box to get dry. No washing of the plates would be required. The next morning he would hang a yellow curtain before his window and put them into his dark slides, developing at night. He would have no dangerous, explosive, strong-smelling, unhealthy collodion to carry about with him on his travels, and he might pack in a very small space enough chemicals in a dry state to last him

for a tour round the world. What a blessing it would be to be independent of collodion and at the same time not to have to trust to the keeping qualities of dry plates."

The Copyright Union.

The assets of the photographer in the way of reproduction fees assumed important proportions as soon as the half-tone reproduction was perfected and gave the impetus to the modern deluge of "popular" periodicals. That was about the year 1892, and photographers to whom Press work was a strange branch of business stood in danger of neglecting their rights. The first formal establishment of a scale of payment for reproduction in the Press was made on July 19, 1893 by a number of photographers meeting at the Hotel Victoria, London. It was then resolved that the minimum charge for reproduction should be one guinea, and that the name and address of the photographer should be legibly printed under each impression. This meeting and one held three months later were private, and were attended only by a few leading London photographers. In January, 1894, a public appeal emanating from the photographic section of the London Chamber of Commerce, was issued, and this was made the occasion for the establishment of a revised minimum fee for reproduction in the Press. Half a guinea, instead of one guinea, was to be this "Copyright Union

minimum." Though it may have seemed the wisest recommendation at the time, its effect has been to make 10s. 6d. a maximum above which a publisher will not go except for special work. Nevertheless, the Union established the principle that a photographer must be paid a fee for the reproduction of his work, and I suppose the recognition of that right is now universal throughout illustrated journalism. Other countries have followed our lead in the institution of a body for the protection of photographers' copyrights—notably France, which has a society embodied with the "Chambre Syndicale de la Photographie," and America, where the photographic interests in regard to reproduction were watched over until recently by the Photographers' Copyright League of America. This body, I learn, is being reorganised under the auspices of the newly-formed Professional Photographers' Society of New York. I understand that there is a movement towards the formation of bodies in the Colonies to discharge these same duties, a sphere in which such influence is particularly desirable, because the law of photographic copyright in these parts of His Majesty's dominions is more honoured in the breach than in the observance, notwithstanding the facts that the Copyright Act is supposed to apply to these countries, and that the Colonies are subscribers to the Berne Convention of International Copyright.

HISTORICUS.

THE BUSINESS SIDE OF PHOTOGRAPHY.

A paper read before the Photographers' Association of Wisconsin.*

WHAT do we mean by the business side of photography? I mean the money-getting side of it; making all the money that you can, out of your artistic efforts. Most of us are "long" on the artistic and "short" on the business side. It is no crime, when people come in for pictures at four dollars per dozen, and the next day when they call for proofs and you show them what an artistic thing it will make in this style at eight dollars per dozen, or this other style of finish and mounting at twelve dollars per dozen (a style, by the way, that you had in mind when you made the sitting, and that you feel sure they would like, if they could only see them finished in that way), it is no crime if you succeed in getting the order at the higher price. This is what I call the business side of it.

I believe the business side of photography should begin when the patron comes into your office. There they should be met by the highest salaried person in your employ; the reception-room lady, who, if she is tactful and a good saleswoman, will more than pay her salary in advanced prices over what they intended to spend when they came into your place.

A Price that is High Enough.

I have heard a great many discussions as to whether it was best to show your low-priced work first, or whether it was better to begin with the highest-priced work. I believe in and pursue the latter course, showing my higher priced work first; of course, "sizing up" my customer, and if you are a close observer you can judge very closely as to what priced work they will stand for. And when they are sent to the operator make the best there is in you, no matter what the price, but make the price high enough even on your cheapest work so that you can give them good service, and this service will bring you another customer or drive one away, dependent upon the product that you deliver to them. Don't be stingy with your plates, and allow so many for such and such priced work.

Look Out for the Unexpected Pose.

I never know how many plates I am going to expose when I go under the skylight. Don't misconstrue my meaning; I

don't mean to be careless and wasteful; but don't stop just because you have made two or three exposures. For instance, I have frequently come to the point where I was apparently done, and would stop to talk for a few moments with the sitter, when he would fall, unconsciously, into an easier and more natural pose. Then I get busy, and make that and possibly another negative, always having a supply of extra holders on my camera. Nine times out of ten that will be your best seller.

How Business Varies, and Why.

I believe a great many of us are careless about our clerical and book work. I have had photographers tell me they never keep books. How in the world do they know how much business they are doing? I once asked a friend how much business he did in a year. His answer was: "Gee! I don't know." I knew he did a good business, but he did not know in dollars and cents. I know what I have done, the first of January of each year. I want to know if I am solvent or otherwise. If business has not been as good as I think it should have been, I want to find out what months were short; the conditions that made it so; and, if I am at fault, correct it. I keep a "stock-house account" and see that my books correspond with theirs. If you discount your bills, that is more of the business side of photography, and is more money in your pocket.

Last year I put in the "card index system" for all office work that we can use it for, and find it a great time saver. I did not like the stock cards as published by the manufacturers, so I figured out one for myself, and had it made by the Yawman and Erbe people, of New York, and it fills the bill.

The Unpaid Proof Problem.

No doubt all of you have the trouble of sitters not reporting on their proofs. This is where the card system makes itself useful. My cards are all kept in a certain compartment until the proofs are returned and the negatives named. The first of each month I go through these cards, and if there are any over thirty days old I write them a nice note, saying that they had a sitting on such a date, and if they were not pleased I shall be glad to give them another sitting. If they

* We are indebted to our New York contemporary, "The Photographer," for the Report.—Eds. B.J.P.

not reply or make an appointment, the next month I send all for services for so much. If they do not respond, the one I send is qualified, "If not paid by," a certain date, a bill will be placed with my attorney for collection." It brings them. That is more of the "business side of photography."

Another proof trouble is, their not returning all the proofs. It is a thing that we positively enforce. I stamp ALL proofs, "Must be returned to the office, otherwise they will be held for." There is scarcely a family in your city that does not have a jar of toning solution in the house, and it is so easy to get the extra proofs, and you lose the extra money. Of course you will have all kinds of arguments put up for a while; but I used to let us keep the proofs we didn't order from," etc., etc. You can tell them that you have adopted a new system of sending all proofs in order to check mistakes in the order, and mistakes do occur. And it is a good idea to do this, too. I have my proofs for nearly a year, and then destroy them. I sometimes send out children's proofs, when I have several of the same child, mounted in combination on a piece of coarse paper so that it can be folded up. This helps to get a few dollars from this class of work.

Making Business.

One may step on someone's toes when I say, "Don't monkey with the ticket schemes and their canvassers." Now, don't think that. You have all, perhaps, been "up against" this proposition. I have, but, thank goodness, only once; and I swore that it would be the last time, and I stuck to it, and am still in business. No telling where I would be if I had stuck to the ticket. Now, I believe in going after business, but on business principles. Don't you know they are making business advertisements, and some of the highest salaried people of the commercial concerns are their advertising managers? Can't we use some of their methods in our business? We can, by sending out dainty booklets and other advertising matter to our patrons, calling attention to something new. If we haven't something new, get busy, and make something new, and call it new. I have an annual Easter exhibit at the time the milliners get through with their "stunts." I came up and get ready the good things that I have made during the past year, and exhibit them. Send out the "swellest" invitations that your printer can give you with. Get the people into your place; let them see what you can do; make them talk about you and you will get their patronage. That, I say, is the business side of photography.

Sometimes you meet someone socially, or a business friend who says he is coming in some of these days to have some work done. Get busy; he brought up the subject. It's "up to you" to get the business. Make an appointment with him right there, at a time suiting his convenience. If he fails to "show up," you have a right to keep at him till you land the business.

Mix with Business Men.

Don't worry about your competitor. Don't try to get his business, but make business for yourself; then try to hold it by making your work and your word good to your customers. Be a representative man in your community. Let them know that even if you are "only a photographer" you are just as good as "the other fellow." One of the best ways to do this is to keep your credit good. A business man will respect you more for this than for all your other good traits. If you have a business or commercial club in your city, join it, and show the other business men that you want to be identified with the welfare of your community. I am a charter member of our chamber of commerce, and know that I command the respect of my business associates, even if I am only a photographer.

I was talking to a friend the other day, whose daughter had attended school for several years in one of our large cities. She wrote him that she wanted some photographs made, that she might send one home to mamma. She went to a man whom we all know has a national reputation. She ordered a dozen at eighteen dollars. When the proofs were sent to my friend there was also one about eight by ten, and he says the photographer wrote him such a nice letter, saying that "the young miss looked so sweet that he just could not resist taking one larger than those she wanted, and perhaps he would like some of them." He would only charge one hundred dollars per dozen for them, or one copy at fifteen.

My friend said, "He wrote me such a nice smooth letter that I just wrote him a check for the extra fifteen." Now, that is that man's business side of photography. Of course he wrote a nice letter. That man has an efficient corps of business getters in his office. That has been the secret of much of his success. He is not only a good workman, but he does not forget the money side of photography. Now, think it over. See if you are putting enough business methods into your business. Do you buy your stock as the merchant would? Do you watch the leaks as you should? Do you display your work so as to create the demand it should, and do you get the prices that you should?

C. J. VAN DEVENTER.

RETOUCHING AND COLOURING PRINTS.

II.

The following notes on the working up of carbon and bromide prints embody the methods of Herr Schultz-Hencke, as described in his *Leitung zur Photographische Retusche*, reviewed last week. A continuing instalment, dealing with the painting and colouring of prints, will appear in our next issue.

Platinotypes.

The absence of glaze on platinotype, and the colour, would lead to think that pencil and chalk could be used; but the former is too much glaze, and the latter is too coarse in the grain. The successful retouching is obtained by treating the prints as though they were on plain paper.

Platinotypes can frequently be considerably improved by passing through a cold burnisher, then giving them a thin coating of the aforementioned albumen-gum solution, letting them dry, and then passing them through the burnisher.

Before commencing to work up a platinotype, the whole print should be damped by brushing it over with one of the largest brushes wetted with water, and then the Indian ink should be applied. If the shadows are too deep or high-lights want lightening, this should not be done by means of colour, but preferably by erasion. For this purpose we may use either the knife or a fairly hard ink eraser. Both must be used cautiously, and with light pressure, and it is better to repeat the application rather than produce the final effect at one application. This method may raise the surface of the paper, but if a highly-glazed paper be bent round the finger tip, and rubbed over the places erased, the surface will be smoothed down, and then these places may be damped with the albumen-gum and further treated, either with colour, knife, or eraser.

Carbon Prints.

The image in these prints, as is well known, is imbedded in

insoluble gelatine, which has some glaze, therefore we must use more gum in our vehicle, and it is frequently more difficult to match the colours. For this reason, some operators dissolve a little of the unexposed tissue in warm water and use the mixture as a pigment to retouch the prints.

Some carbon tissue makers issue special colours for retouching prints on their tissues, and then the work is, of course, much simplified. In any case, if a high-light is to be lightened, Chinese white cannot be used, but we must employ erasion—knife or eraser—though in either case the work is not easy, and requires considerable practice.

Bromide Prints.

The existing fashion in enlargements is for rough or half-matt surfaces, which present no trouble to the retoucher, for they can be worked up with stump and chalk or crayon without much trouble; still, it is advisable to give the prints a coating of water-colour varnish or shellac dissolved in alcohol, and, if they are to be worked up with pastels, the surface should be roughened with pumice powder. If bromides are also coated with warm gelatine solution they can be painted in oils without much trouble.

For spotting or working up with chalks, Hardtmuth's black chalks Nos. 1, 2, and 3, and Nos. 1, 2, 3, 4, and 5 of the "negro pencils" are the most suitable. Stumping chalk and stumps of various sizes, a plain leather pad, scraper, knife, and ink eraser are also required.

Fig. 1.—The first stroke.

Fig. 2.—The second stroke.

Fig. 3.—The completed tint.

For sharpening the pencils a piece of prepared pumice stone is the best thing.

Retouching of bromide prints is generally and preferably done with the above materials, as it is easier to match the colour and surface of the prints than with water colours, and whites should be put in with the scraper or eraser, and not with Chinese white.

Drawing charcoal should also be provided, and this should be scraped and mixed with the chalk if required, and the best method of doing this is to rub the leather pad with the charcoal and chalk, and then mix the powders with the finger tip or the stump. The use of the finger is very common, but there is no doubt that it is far better to use the stump, as this entirely obviates any chance of greasy marks. The beginner should always adhere to the stump though, whilst, with experience, the finger may be used for putting in extremely delicate work.

The powder having been mixed, the stump should be charged with the same, and any excess of powder wiped off on the leather pad and then the stump applied very lightly to the print with broad, sweeping strokes. Pressure should be avoided as much as possible, otherwise the surface will become glazed, and it makes it more difficult to remove excess of the chalk or to put more on. If the tone is too deep, excess should be removed with a soft leather wrapped round the finger, or in the form of a stump. Both these methods, however,

must be lightly used. It is always easy if one end of the stump kept clean, as it should be, to lighten a spot or equalise the touching, and this can take the place of the leather stumps.

Shading or Cross-Hatching.

For working up backgrounds it is usual to resort to cross-hatching. The work requires practice, and is somewhat tedious when properly done, but the more care taken over it the more effective it is. Practically, it consists in the crossing of numerous parallel lines, and the more lines used the more effective the result and the less it has the appearance of line and the more it gives the effect of grain. The method of working is extremely suitable for large surfaces, and with some artistic skill, it is possible to put in suggestions of form.

In cross-hatching, right angles should be avoided in crossing the lines, and rhomboids or diamonds should, for preference, be the form primarily aimed at in the first two sets of crossing lines; then the third line should divide the diamonds down their length, and in the little white interspaces should now be put a dot. The result is a more or less broken tone, which can, if necessary, in the deeper parts, be converted into closed tones by the use of the stump.

As has already been pointed out, the whites are put in with the knife or eraser, but for clearing up deep tones and large areas the eraser or the softer indiarubber may be successfully used, as may also bread-crumbs.

As a rule, it will be found advantageous to work up the background first, and then turn the attention to the head. The hair may be darkened or worked up, and details put in with the stump or even the pencil. A tint may be put over the whole of the face, and the lights afterwards put in by removal of the chalk with the leather or bread-crumbs. The main thing is to do as much work with the stump and leather, and leave as little as possible for the pencil. For very deep tones, Hardtmuth's chalk in wood "No. soft" (this is the official title) should be used, and lines or "grain" put in, and these broadened with the stump.

When the whole of the work is done the chalk will be entirely removed from the surface, and an accidental touch will remove it. It is necessary, therefore, to fix it, and for this purpose "fixative," which is a commercial preparation, should be used—though white shellac, dissolved by the aid of heat in alcohol and filtered, acts equally well, and, whichever is used, it must be applied by means of a spray diffuser.

In our issue for June 30, p. 506, Mr. Whiting deals with the question of fixative and the best method of applying it.

On the working up of bromides with "mechanical" aids, such as the electric retouching pencil and the aerograph, we do not think necessary to treat; the latter, in particular, being so well known and giving such excellent results as to place it far above any "hand" work.

THE PHOTOGRAPHIC CONVENTION OF THE UNITED KINGDOM.

TWENTIETH MEETING: DUBLIN.

The twentieth meeting of the Photographic Convention opened at Dublin on Monday, July 10. The headquarters of the Convention are the Engineering School of Trinity College, and early on Monday a large number of members had put in an appearance, and had formed into parties for the inspection of the sights of the Irish capital. Monday is a "go-as-you-please" day at the Convention, for the formal opening of the proceedings does not take place until the evening of that day, when the presidential address is delivered and a reception held by the president. Fine weather, relieved by one or two small showers in the early morning, belied the reputation of Dublin for persistent rain, and, as a result, the honorary secretary (Mr. F. A. Bridge) and the local honorary secretary (Mr. Robert Benson) were busy enrolling members and dispensing tickets for the three excursions which are held during the Convention week. The following list may be taken as representing the arrivals up to Monday morning, though, for obvious reasons, it does not claim to be complete:—Mr. W. Taylor (Leicester), Mr. E. J. Humphery (London), Mr. C. H. Bothamley, F.I.C. (Weston-super-Mare), Mr. and Mrs. Alfred Ellis (London), Mr. E. Llewellyn White (London), Mr. F. W. Hindley (London), Mr. T. C. Turner (Hull), Mr. T. K. Grant (London), Mr. Hedley, Mrs. and Miss Smith (London), Messrs. F. W. Sanderson and Goodrich (Cambridge), Mr. George E. Brown, F.I.C. (London), Mr. and Mrs. R. R. Beard (London), Mr. A. E. Atkins (Elstree), Mr. Thorne Baker (London), Mr. A. and Miss Ethel Seaman (Sheffield), Mr. W. H. Smith (London), Mr. W. E. Dunmore (London), Mr. Godfrey Bingley (Leeds), Mr. and Mrs. Spink (Brighton), Mr. and Mrs. De'Ath (Ashford), Miss Ethel Crowther (Derby), Miss R. Goodey (Derby), Mr. Courtney Wells (Gloucester), Mr. and Mrs. J. L. Cox (Macclesfield), Mr. and Mrs. H. Snowden Ward (London), Mr. and Mrs. F. A. Bridge (London), Mr. A. Clout (West Malling), Mr. Walter Potter (Hackney), Mr. and Mrs. Brand (Kinnowel), Mr. and Mrs. Atkinson (Leeds), Mr. and Mrs. Knoblauch, Mr. Temple, Mr., Mrs., and Miss Norton (Oxford), Mr. B. Tompkins (Leeds), Mr. F. B. Catley, Mr. and the Misses Powell (Bath), Mr. and Mrs. Norval (Dunfermline), Mr. White (Dunfermline), Messrs. C. Morgan Smith and S. J. Smith (South Norwood), Mr. and Miss Williamson (Newcastle-on-Tyne), Mr. Errington Cowan (Newcastle-on-Tyne), Mr. A. Bedding (Kilmarnock), Mr. M. S. Bedding (Clapham), Mr. C. A. Blackburn (Leeds), Mr. W. Davies (Sydney, N.S.W.), Mr. J. Taylor (Leeds), Mr. E. J. Walker (Wakefield), Mr. and Mrs. D. E. Benson (Southport), Mr. H. Vivian Yeo (Dublin), Dr. J. Alfred Scott (Dublin), Mr. and Mrs. Cox (Heaton Chapel), Mr. James McGhie (Glasgow), Mr. and Mrs. B. Catley (Harrogate), Mr. and Mrs. Paul Ponge (London). Professor J. Joly, F.R.S., D.Sc., president for the year, arranged

for a visit to portions of Trinity College, and members of the Reception Committee (already published in these columns) kindly placed their services at the disposal of the visitors. A word should not be omitted in appreciation of the tireless efforts of the secretaries of the

PROFESSOR J. JOLY, F.R.S., D.Sc.,
President of the Dublin Convention, 1905.

[A. Werner.

committees towards ensuring the pleasure and comfort of the guests. Thanks to their well-considered plans, the machinery of the Convention worked with all desirable smoothness.

"THE LATENT IMAGE."

[The following is the full text of Professor J. Joly's address delivered on Monday evening last, July 10.]

My inclination has led me, in spite of a lively dread of incurring a charge of presumption, to address you principally on that profound and most subtle question—the nature and mode of formation of the photographic image. I am impelled to do so not only because the subject is full of fascination and hopefulness, but because the wide topics of photographic methods or photographic applications would be quite unfittingly handled by the President you have chosen. I have already had the honour upon two occasions of bringing ideas on this subject before the Photographic Society of Ireland, and the Photographic Society has, with much patience and fortitude, listened to my views, or my statement of the views of others. I do not propose to try your patience in the same relentless manner. You will notice that the Committee, rendered wise by past experience, has wisely limited the time at my disposal. I will therefore make my remarks brief.

Photo-Sensitiveness at Low Temperatures.

I would first draw your attention to Sir James Dewar's remarkable result that the photographic plate retains considerable power of forming the latent image at temperatures approaching the absolute

zero. A result which, as I submit, compels us to regard the fundamental effects progressing in the film under the stimulus of light undulations as other than those of a purely chemical nature. But few, if any, instances of chemical combination or decomposition are known at so low a temperature. Purely chemical actions cease, indeed, at far higher temperatures; fluorine being among the few bodies which still show chemical activity at the comparatively elevated temperature of 180 deg. C. In short, this result of Sir James Dewar's suggests that we must seek for the foundations of photographic action in some physical or intra-atomic effect, which, as in the case of radio-activity, or fluorescence, is not restricted to intervals of temperature over which active molecular *vis viva* prevails. It compels us to regard with doubt the rôle of oxidation or other chemical action as essential, but rather points to the view that such effects must be secondary or subsidiary. We feel, in a word, that we must turn for guidance to some purely photo-physical effect.

The Strain Feature of the Latent Image.

Here, in the first place, we naturally recall the views of Dr. Bose. This physicist would refer the formation of the image to a strain of

the bromide of silver molecule under the electric force in the light wave, converting it into what might be regarded as an allotropic modification of the normal bromide which subsequently responds specially to the attack of the developer. The function of the sensitiser, according to this view, is to retard the recovery from strain. Bose obtained many suggestive parallels between the strain phenomena he was able to observe in silver and other substances under electro-magnetic radiation, and the behaviour of the photographic plate when subjected to long continued exposure to light.

This theory, whatever it may have to recommend it, can hardly be regarded as offering a fundamental explanation. In the first place, we are left in the dark as to what the strain may be. It may mean many and various things. We know nothing as to the inner mechanism of its effects upon subsequent chemical actions; or, at least, we cannot correlate it with what is known of the physics of chemical activity. Finally, as will be seen later, it is hardly adequate to account for the varying degrees of stability which may apparently characterise the latent image. Still, there is much in Dr. Bose's work deserving of careful consideration. He has by no means exhausted the line of investigation he has originated.

A Photo-Electric Hypothesis.

Another theory has doubtless been in the minds of many. I have said we must seek guidance in some photo-physical phenomenon. There is one such which pre-eminently connects light and chemical phenomena through the intermediary of the effects of the former upon a component part of the atom. I refer to the phenomena of photo-electricity. It was ascertained by Hertz and his immediate successors that light has a remarkable power of discharging negative electrification from the surface of bodies—especially from certain substances. For long no explanation of the cause of this appeared. But the electron—the ubiquitous electron—is now known with considerable certainty to be responsible. The effect of the electric force in the light-wave is to direct or assist the electrons contained in the substance to escape from the surface of the body. Each electron carries away a very small charge of negative electrification. If, then, a body is originally charged negatively, it will be gradually discharged by this convective process. If it is not charged to start with, the electrons will still be liberated at the surface of the body, and this will acquire a positive charge. If the body is positively charged at first, we cannot discharge it by illumination.

Electrons and Ionisation.

It would be superfluous for me to speak here of the nature of electrons, or of the various modes in which their presence may be detected. Suffice it to say, in further connection with the Hertz effect, that when projected among gaseous molecules, the electron soon attaches itself to one of these. In other words, it ionises a molecule of the gas, or confers its electric charge upon it. The gaseous molecule may even be itself disrupted by impact of the electron, if this is moving fast enough, and left bereft of an electron. We must note here that such ionisation must be regarded as conferring potential chemical properties upon the molecules of the gas and upon the substance whence the electrons are derived. Similar ionisation under electric forces enters, as we now believe, into all the chemical effects progressing in the galvanic cell, and, indeed, generally in ionised solutions.

I have here a simple experiment which will at once illustrate the principles I wish to remind you of. A clean aluminium plate carefully insulated by a sulphur support, is faced by a sheet of copper-wire gauze placed a couple of centimetres away from it. The gauze is maintained at a high positive potential by this dry pile. A sensitive gold leaf electroscope is attached to the aluminium plate, and its image thrown upon the screen. I now turn the light from this arc lamp upon the wire gauze, through which it in part passes and shines upon the aluminium plate. The electroscope at once charges up rapidly. There is a liberation of negative electrons at the surface of the aluminium; these, under the attraction of the positive body, are rapidly removed as ions, and the electroscope charges up positively.

Again, if I simply electrify negatively this aluminium plate, so that the leaves of the attached electroscope diverge widely, and now expose it to the rays from the arc lamp, the charge, as you see, is very rapidly dissipated. With positive electrification of the aluminium there is no effect attendant on the illumination.

The Electron in Photographic Action.

Thus from the work of Hertz and his successors we know that light, and more generally what we call actinic light, is an effective means of freeing the electron from certain substances. In short, our photographic agent—light—has the power of evoking from certain substances the electron which is so potent a factor in most, if not all, chemical effects. I have not time here to refer to the work of Elster and Geitel, whereby they have shown that this action is to be traced to the electric force in the light wave, but must turn to the probable bearing of this phenomenon on the familiar facts of photography. I assume that the experiment I have shown you is the most funda-

mental photographic experiment which it is now in our power to make.

We must first ask from what substances can light liberate the electron. There are many; metals, as well as non-metals and liquids. It is a very general phenomenon, and must operate widely throughout Nature. But what chiefly concerns the present consideration is the fact that the haloid salts of silver are vigorously photo-electric, and possess, according to Schmidt, an activity in the descending order bromide, chloride, iodide. This is, in other words, their order of activity as ionisers (under the proper conditions) when exposed to ultra-violet light. Photographers will recognise that this is also the order of their photographic sensitiveness.

Photo Electric Activity and Light Absorption.

Another class of bodies also concerns our subject—the special sensitisers used by the photographer to modify the spectral distribution of sensibility of the haloid salts, e.g., eosine, fuchsin, cyanine. These again are electron-producers under light-stimulus. Now it has been shown by Stoletow, Hallwachs, and Elster and Geitel that there is an intimate connection between photo-electric activity and the absorption of light by the substance; and, indeed, that the particular wave lengths absorbed by the substance are those which are effective in liberating the electrons. Thus we have strong reason for believing that the vigorous photo-electric activity displayed by the special sensitisers must be dependent upon their colour absorption. You will recognise that this is just the connection between their photographic effects and their behaviour towards light.

Photo-Electrics and Temperature.

There is yet another suggestive parallel. I referred to the observation of Sir James Dewar as to the continued sensitiveness of the photographic film at the lowest attained extremes of temperature, and drew the inference that the fundamental photographic action must be of intra-atomic nature and not dependent upon the *vis viva* of the molecule or atom. In then seeking the origin of photographic action in photo-electric phenomena we naturally ask: Are these latter phenomena also traceable down to low temperatures? If they are we are entitled to look upon this fact as a qualifying characteristic, or as another link in the chain of evidence connecting photography with photo-electric activity.

I have quite recently, with the aid of liquid air kindly supplied to me by Mr. Moss, and made in the laboratory of this Society, tested the photo-sensibility of aluminium, and also of silver bromide, down to temperatures approaching that of the liquid air. The mode of observation is essentially that of Schmidt—what he terms his static method. The substance undergoing observation is, however, contained at the bottom of a thin copper tube, which is immersed to a depth of about 10 cm. in liquid air. The tube is closed above by a paraffin stopper which carries a thin quartz window as well as the sulphur tubes through which the connections pass. The air within is very carefully dried by phosphorous pentoxide before the experiment. It was found that a vigorous photo-electric effect continued in the case of the clean aluminium. In the case of the silver bromide a distinct photo-electric effect was still observed. I have not had leisure to make, as yet, any trustworthy estimate of the percentage effect at this temperature in the case of either substance. Nor have I determined the temperature accurately. The latter may be taken roughly as about -150°C . Sir James Dewar's actual measurements afforded 20 per cent. of the normal photographic effect at -180°C . and 10 per cent. at the temperature of -252.5°C .

The Basis of a Physical Theory.

With this much to go upon, and the additional fact that the electronic discharge—as from the X-ray tube or from radium—generates the latent image, I think we are fully entitled to suggest as a legitimate lead to experiment the hypothesis that the beginnings of photographic action involve an electronic discharge from the light-sensitive molecule. In other words, that the latent image is built up of ionised atoms, or molecules, the result of the photo-electric effect upon the illuminated silver haloid, and upon these ionised atoms the chemical effects of the developer are subsequently directed. It may be that the liberated electrons ionise molecules not directly affected, or it may be that in their liberation they disrupt complex molecules built up in the ripening of the emulsion. With the amount we have to go upon we cannot venture to particularise. It will be said that such an action must be in part of the nature of a chemical effect. This must be admitted, and in so far as the rearrangement of molecular fabrics is involved the result will doubtless be controlled by temperature conditions. The facts observed by Sir James Dewar support this. But there is involved a fundamental process—the liberation of the electron by the electric force in the light-wave, which is a physical effect, and which, upon the hypothesis of its reality as a factor in forming the latent image, appears to completely explain the outstanding photographic sensitiveness of the film at temperatures far below those at which chemical actions in general cease.

again, we may assume that the electron-producing power of the special sensitiser or dye for the particular ray it absorbs is responsible, or responsible in part, for the special sensitiveness it confers on the film. Sir Wm. Abney has shown that these sensitisers are active, even if laid on as a varnish on the sensitive surface, are removed before development. It must be remembered that fairly high temperatures these sensitisers lose their influence on film. (See a paper by me read before the Convention in 1894.)*

An Explanation of Recurrent Reversal.

It appears to me that on these views the curious phenomenon of recurrent reversals does not present a problem hopeless of explanation; for the process of photo-ionisation constituting the latent image, where the ion is probably not immediately neutralised by chemical combination, presents features akin to the charging of a capacity—say a Leyden jar. There may be a rising potential between groups of ions till ultimately a point is attained when there is a spontaneous neutralisation. I may observe that the phenomena of reversal appear to indicate that the latent change upon the silver halide molecule, whatever be its nature, is one of gradually increasing intensity, and finally attains a maximum when a return to the original condition occurs. The maximum is the point of most developable image. It is probable that the sensitiser—in the case the gelatine in which the bromide of silver is immersed—takes a part in the conditions of stability which are involved.

Degrees of Stability in Latent Images.

Of great interest in all our considerations and theories is the present work of Professor Woods on photographic reversal. The result of this work is—as I take it—to show that the stability of the latent image may be very various, according to the mode of its formation. Thus it appears that the sort of latent effect which is produced by pressure or friction is the least stable of any. This may be reversed or wiped out by the application of any other known form of photographic stimulus. Thus an exposure to X rays will obliterate or a very brief exposure to light. The latent image arising from X rays is next in order of increasing stability. Light-action will overcome this. Third in order is a very brief light-shock, or sudden

flash. This cannot be reversed by any of the foregoing modes of stimulation, but a long-continued undulatory stimulus, as from a lamp, will reverse it. Last and most stable of all is the gradually built up configuration due to long-continued light-exposure. This can only be reversed by overdoing it, according to the known facts of recurrent reversal. Professor Woods takes occasion to remark that these phenomena are in bad agreement with the strain theory of Dr. Bose. We have, in fact, but the one resource—the allotropic modification of the haloid—whereby to explain all these orders of stability. It appears to me that the elasticity of the electronic theory is greater. The state of the ionised system may be very various according as it arises from continued rhythmic effects or from unorganised shocks. The ionisation due to X rays or to friction will probably be quite unorganised; that due to light more or less stable according to the gradual and gentle nature of the forces at work. I think we are entitled to conclude that on the whole there is nothing in Professor Woods's beautiful experiments opposed to the photo-electric origin of photographic effects, but that they rather fall in with what might be anticipated.

When we look for further support to the views I have laid before you we are confronted with many difficulties. I have not as yet detected any electronic discharge from the film under light stimulus. This may be due to my defective experiments, or to a fact noted by Elster and Geitel concerning the photo-electric properties of gelatine. They obtained a vigorous effect from Balmann's luminous paint, but when this was mixed in gelatine there was no external effect. Schmidt's results as to the continuance of photo-electric activity when bodies in general are dissolved in each other lead us to believe that an actual conservative property of the medium and not an effect of this on the luminous paint is here involved. This conservative effect of the gelatine may be concerned with its efficacy as a sensitiser.

In the views I have laid before you I have endeavoured to show that the recent addition to our knowledge of the electron as an entity taking part in many physical and chemical effects may be availed of, and should be kept in sight in seeking an explanation of the mode of origin of the latent image.

J. JOLY.

CONVERSAZIONE AND EXHIBITION.

On Monday evening the official reception by the president was held at the Royal Dublin Society's Buildings. The address printed was afterwards delivered by Professor Joly, Sir Howard Crosby, F.R.S., president of the Convention on its former visit to Dublin, occupying the chair. At the conclusion of the address, a vote of thanks to Dr. Joly was proposed by Mr. C. H. Bothamley. Conversation followed in the Museum, decorated for the occasion, presenting a brilliant spectacle. The orchestral band of the Royal Irish Constabulary contributed an excellent selection of music till the evening.

On Tuesday a large number availed themselves of the excursion to Malinbegh, and yesterday (Thursday) Bray and the Dargle were visited.

An exhibition of photographs and photographic materials is being held during the week in the Leinster Hall, Molesworth Street, adjoining Trinity College. The largest exhibition is by the Platinotype Company, London, represented by Messrs. W. H. Smith and E. Dunmore, who were responsible for the arrangement of a fine and varied collection of professional portraiture by leading artists, chiefly in the United States, and on the Continent. The motive was made of Platinotype paper in these exhibits was one of the most educative features of the exhibition, and professional members of the Convention—a considerable proportion—had also opportunity of studying the styles and methods of their confrères of the front rank in America and Germany. Among those whose work, in platinotype, was thus shown may be mentioned J. C. Cass, St. Louis; Steffens, Chicago; Benjamin, Cincinnati; Wright Cook, Philadelphia; and Garo, Boston. With these, also, should be named work by Trusberger, Benque and Kindermann, A. Bridgman, H. P. C. Harpur, Goldensky, Frank Moore, and A. Reineke. The portraiture by these professionals is largely of a strong character, to which the British photographer is less accustomed than are the moving spirits of studios in the States, but qualified praise can be given to the great majority of the work, which is good as portraiture, and better still, perhaps, in its variety of that most beautiful and elastic printing process, platinotype. Several prints, in which a light-tinted border had been traced round the picture, and was itself bordered by a margin of the same paper, impressed us as particularly deserving of study. Demonstrations of the process are being given at intervals, and the well-known magnesium lamp of the Platinotype Company is also utilised in a gallery, and a number of portraits taken by it.

* B. J., July 20, 1894, p. 453.

Photolinol, Limited, London (represented by Messrs. Otto Fulton, F.R.P.S. and I. J. Temple), showed a considerable variety of enlargements on their sensitised linen, finished in pastel, sepia, water-colour, or oil. Specimen prints on a new brand (Angelo) of platinum paper were also shown by them, and included sepias made on a cold development paper. A novel series of original background designs with the well-known transparencies, plain and coloured, made up a varied exhibit.

Messrs. Ellis and Walery, 51, Baker Street, London, show half-a-dozen theatrical studies, emphasising the command of strong lighting which characterises this well-known firm's work. One was a fine portrait of Mr. Beerbohm Tree, and another a study of Mr. George Alexander as François Villon, taken on the stage by electric light.

Lafayette, Limited, show a few portraits, commanding in subject and in style of mounting. Several are of beautiful women and children, and the best is a bold piece of portraiture of the Countess of Tankerville and child.

J. Robinson and Sons, Limited, 65, Grafton Street, Dublin, have eight frames, including an oil painting of Lord Roberts, from one of their most popular portraits of the Commander-in-Chief.

Dublin photographers of all men are favoured in their subjects, and in Dublin a photographer's show-case is a portrait gallery of beautiful women. That description applies particularly to the exhibits of Messrs. Chancellor, who make very effective use of oval and circle forms of print. Mr. Bradshaw's work is similar.

Mr. Alfred Werner elected to be represented by one portrait only—that of the president, Professor J. Joly—and reproduced on a preceding page. Mr. D'Arcy showed enlargements in different styles, and a number of coloured miniatures.

Next Year's Meeting.

The annual meeting of the Convention was held on Wednesday morning, at Trinity College, when, on the invitation of the Southampton Camera Club, it was decided to hold the 1906 meeting at Southampton. Officers were elected, and a meeting of the new council held. In the afternoon a garden party was held in the Zoological Gardens by Sir Howard and Lady Grubb, and the annual dinner and smoking concert took place in the evening at the Gresham Hotel, Sackville Street. To-day (Friday), after "To Drogheda," an illustrated paper on "The Use of Extremely Rapid Plates" is to be read by Mr. Thorne Baker, F.C.S.

THE SCOTTISH PHOTOGRAPHIC FEDERATION "BLUE-BOOK" FOR 1905.

This little publication holds the same position in the esteem of the federated Scottish societies that the familiar "Red-Book" does among the affiliated English societies, and its objects and achievements appear to be on similar lines. Particulars of the Federation and competitions, etc., are given, and an admirable gazetteer of places of interest in Scotland for photographers is included.

Two new features are added this year which will be greatly appreciated. One is the appointment of an efficient staff of "experts" in photographic matters. A number of gentlemen have kindly agreed to advise Associates on the various subjects mentioned, and the only condition imposed is that postage must be paid by those requesting advice for return of specimens, etc.

This should prove a very popular addition to the usefulness of the Federation, especially when the extent of the subjects upon which expert advice will be given is seen. They include Apparatus, etc., Optics, Orthochromatic Photography, Stereoscopic Photography, Pin-hole Photography, Composition, Development, Chemistry of Developers, Films, Bromide and Gaslight Papers, Carbon Printing, Gum-Bichromate, Plain Salted Papers, Platinotype Printing, Lantern Slides, Ozotype, Animal Photography, Flower Studies, Geological Photography, Microscopic Photography, Survey Work, Woodland Photography, X-ray Work, and Mounting and Framing, etc. The names and addresses of several gentlemen well known in photography north of the Tyne appear in each sub-section, and we consider that an important step in further binding the societies together has been taken in thus instituting this "expert" department, which should be taken full advantage of by the Associates.

The other new feature is the appointment of local "reporters." In addition to the usual photographic information given respecting each place of interest mentioned in the gazetteer, lists of dark-rooms are supplied, and, in addition, local reporters are appointed for each town. The function of these gentlemen is to supply full information about the districts above their names on receiving a request accompanied by a stamped and addressed envelope.

The following note is also addressed to the Associates:—"Additions to, or correspondence on, the following information (the Gazetteer) will be welcomed from all associates. Associates on tour will be doing a service to the Federation by sending details of places visited, dark-rooms, etc., to the Secretary. The list of dark-rooms given are free for changing, to Associates away from their own districts, on presentation of the "Blue-Book."

The present issue of this useful little book is 2,500, and the advertisements fully demonstrate that advertisers are beginning to note the value of this medium of reaching Scottish photographers.

Congratulations to Secretary MacLachlan on its production.

At the annual "At Home" held at the president's residence, Alston Lodge, Ilford, the members of the South Essex Camera Club presented the president (Mr. Walter D. Welford) with a silver cigarette case and match box, suitably engraved. Mrs. Welford, who is a vice-president, also received silver-mounted toilet requisites. The case was engraved, "To President Welford as a token of esteem."

THE OPTICAL SOCIETY.—At the final meeting in the present session of the Optical Society Lord Kelvin and Sir William Christie, Astronomer Royal, were elected honorary members of the Society.

MR. ROBERT C. MURRAY, photographic and scientific instrument maker, informs us that he has removed his office to No. 13, Garrick Street, on the ground floor (Messrs. Suckling and Co., booksellers), opposite to his old address for the past many years. The new address should be noted by Mr. Murray's many patrons.

Exhibitions.

THE ILFORD COMPETITION PRINTS.

In our last issue we published the list of names of the prize-winners in the Ilford £750 cash prize competition, and on Friday last we were enabled to view the winning prints at The Modern Gallery, 6, New Bond Street, London, W., where they are now on exhibition. This exhibition was opened to the public, admission free, on Saturday, and remains open until 6 p.m. this evening (Friday). Over 400 photographs are on view, and the show is a notable one in many respects than one. It gives a very clear idea of the ubiquity of the famous Ilford firm; photographs from every part of the world are to be seen here. Prints from far Ceylon hobnob with specimens of the photographic industry from Victoria, and striking examples of Russian snapshots hang cheek-by-jowl with work from Java. Of course, the exhibits by English photographers predominate, as might be expected, but the cosmopolitan nature of the entries, and the fact that every picture is produced on Ilford materials, must be extremely gratifying to the organisers. It will be remembered that in the announcement of the competition, made some time ago, £380 was the sum set aside for prizes for professional photographers only; £282 10s. was for amateurs, and £87 10s. for junior amateurs. The actual money prize awarded considerably exceeded these sums. We understand this was necessary owing to the enormous number of entries and their average standard of merit.

No indication of the authors of the pictures is given on the exhibition, but it is not difficult to identify the work of Will Cadby, Mrs. G. A. Barton, and other well-known amateurs, whose names figure with regularity in these prize competitions. As many competitors did not wish their names announced in the prize list, the organisers decided not to affix either the names of the photographers or the amounts of the prizes on the pictures, but this does not detract one iota from the pleasure a contemplation of these photographs must give to every visitor.

The prints have been uniformly framed in neat brown oak frames, but in every case the original mounting of the photographs has been left intact. The walls being covered with a light shade of neutral brown, the entire effect is very pleasing; and the lighting of the Gallery is excellent.

Some very good beginners' work was pointed out to us, and, among the higher pictorial work, landscapes and figures were in the majority. There is very little obviously "professional" photography on view—that is, the usual show-case type of thing, and for this we are thankful, well knowing that a great bulk of the pictures are by professional photographers. The processes employed appear to be fairly evenly distributed between Ilford bromide papers, Ilford P.O.P., and Ilford Platona paper. One or two striking prints, on the last-named particularly, attracted our attention by reason of their fine quality and "juicy shadows," well demonstrating the excellent properties of this product. A large landscape subject by H. S. Parsons is notable in this respect. It is a big print, about 20 by 16, and possesses all the attributes of a fine composition.

J. C. Warburg has a pleasing little study in "And Pulled Out Plum," and an admirable little landscape of a fine colour is shown by George Brown. Another landscape, with some splendid colour forms that possess the quality of a good water-colour drawing, is from Ormonde E. Challis, and proves beyond question the advantages of using the Isochrom plate. A flashlight interior by W. Page is one of the best of its kind we remember having seen, and a male costume model subject entitled "Awaiting Developments" is also noteworthy, as possessing none of the incongruities usually associated with attempts of this sort by photography. It is by J. H. Symington.

A series of five very fine instantaneous photographs of torpedo boat destroyers and battleships under full steam are sure to attract considerable attention.

Not only are they very excellent examples of high-speed work, but they possess striking pictorial qualities. In addition to this, the facts that the craft depicted are Russian and the photographs are by an officer of the Russian Navy will considerably add to their interest. Two delightful figure studies by ladies are among the best things in the show. One is by Mrs. L. A. Armour, of the United States, and all the qualities of a fine etching, and the other is by Mrs. C. Comnor. A dainty child study by Will Cadby is in this worker's best style, and a clever flower study by B. J. Jackson deserves attention.

Mrs. G. A. Barton's contribution is well chosen. A large print on Platina paper, depicting some old Dutch houses and delightful reflections, is an example of very high technical work combined with pictorial merit. It is by F. Jonson. A fine effect of a river streaming between headlands of a valley to the sea, and the setting sun is shown in a picture by E. W. Taylor, and work by A. W. Adreé, of Ceylon, Herbert Bairstow, Graystone Bird, H. Kuijk, of Java, A. K. Chatterjee, Miss Constance Collier, Captain A. d'Azevedo Silva, Dan Dunlop, Albert Durn, C. A. Hoppé, S. Ishizu, Walter Ilbey, S. G. Kimber, Mrs. R. M. King, A. J. Campbell, of South Australia, H. C. Leat, H. T. Malby, Ernest Marriage, J. O. Mba, Pike, Clarence Ponting, Victor Stouffs, Misses A. and E. Tomson, Mrs. J. Welford, and many others helps to swell the display of good things. The Ilford Company are to be congratulated on the result of their efforts, and both the competition and the exhibition could bring them a goodly return.

THE AEROGRAPH EXHIBITION.

An exhibition of the drawings and photographs in which that well-known instrument the aerograph has been used, has just closed in London, and the promoters may be congratulated on having brought together a most interesting collection of work, including not only photographic portraits "finished" by the aerograph, and photographs for process reproduction worked up by the same means, but also jewellery, decorations on pottery and silk, Christmas cards, window tickets, and hand drawings, the means of production in each case being solely partially the aerograph. The sum of 100 guineas in prizes was offered by the Aerograph Company, Limited, and the following awards were made by J. Martin Wood (of the editorial staff of "The Studio"), George E. Brown (THE BRITISH JOURNAL OF PHOTOGRAPHY), and William Gamble (editor of "The Process Year Book") :—Freehand drawing—1, S. Winney, 34, Stillness Road, Forest Hill, S.E.; 2, David L. Wilson, 121, Cartvale Road, Langside, Glasgow. Photographs—1, H. Gordon Chase, Broadway Studio, Tunbridge Wells; 2, Miss Robinson, Littleton House, High Road, North Tottenham. Finishing for Process—1, Wilson and Hudson, Gravens, Manchester; 2, Percy T. Edwards, Thanet House, 231, and Window Tickets and Show Cards—1, A. Andrews, 78, Narne Avenue, Clapham Common; 2, Dyke Brothers, 583, Mare Street, Hackney, N.E. Christmas Cards—1, W. Harrison, 15, Forest Avenue. Jewellery and Metal Enamelling.—Frederic Crane, Chemical Company, Birmingham. Mural Decorations.—Sanderson and Son, Chiswick, S.W. Commended—Miss Elsie M. Jenkins, 200, Kent Street, W.; and Mr. Evans (Clements and Newling), 28, Russell Street.

The Gateshead Camera Club has secured rooms at the Mechanics' Institute, Gateshead, on good terms, and the annual subscription is reduced to five shillings. The new premises, it is hoped, will afford better comfort and convenience to the members and result in an increase in their numbers.

FORTHCOMING EXHIBITIONS.

July 4 to August 12.—Northern Photographic Exhibition. Secretary, F. G. Issott, 62, Compton Road, Harehills, Leeds.

July 15-25.—Sixth International Salon Association Belge de Photographie, Liège. Secretary, Mr. Servais, 34, Rue du Saint-Esprit, Liège.

August 7.—Andover. Hon. Secretary, W. I. Gradidge, Jubilee House, Andover.

August 24 to September 21.—Berwick-upon-Tweed Arts Club. Hon. Secretary Pictorial Photography Section, H. Hancock, 56, Ravensdowne, Berwick-upon-Tweed.

September 8.—International Exhibition at Budapest. Address, Secretary of the Photo-Club, Egyetem-ter 5, Budapest, IV.

September 15-October 21.—Photographic Salon, 5a, Pall Mall East. Hon. Secretary, Reginald Craigie, Camera Club, Charing Cross Road, W.C.

September 21-October 23.—Royal Photographic Society, New Gallery, 121, Regent Street, London, W. Secretary, J. McIntosh, 66, Russell Square, London, W.C.

October 19-21.—Grangemouth Amateur Photographic Association. Hon. Secretary, Robert Marshall, 3, Park Terrace, Grangemouth.

October 28-November 4.—Sheffield Photographic Society. Joint Hon. Secretaries, J. W. Charlesworth, 1 Joshua Road, Sheffield, and James W. Wright, 62, Vale Road, Sheffield.

November.—Edinburgh University C.C. Hon. Secretary, Harold C. Simpson, University Union, Edinburgh.

November 3, 4, 5.—Motherwell Young Men's Institute C.C. Hon. Secretaries, James Dunlop, Myrtlebank, Motherwell, and Archibald Matthews, 24, Enfield Place, Ladywell, Motherwell.

November 8-15.—Croydon Camera Club. Hon. Sec., W. H. Rogers, 88, Woodville Road, Thornton Heath.

November 14, 15, 16.—Ipswich Camera Club. Hon. Sec., R. H. Sutton, 37, Henley Road, Ipswich.

November 21-25.—Southampton Camera Club. Hon. Secretary, S. G. Kimber, Oakdene, Highfield, Southampton.

November 25-December 2.—Glasgow Eastern Amateur Photographic Association.

November 25-December 2.—Glasgow Eastern A.Ph.A. Hon. Secretaries, Thomas B. Kirkhope, 37, Winston Street, Parkhead, Glasgow, and John Brough, 68, Dalmarnock Street, Parkhead, Glasgow.

December.—Muirkirk A.Ph.A. Hon. Secretary, William Barrowman, Ayr View, Muirkirk.

December 1-6.—Hove Camera Club. Hon. Secretary, A. R. Sargeant, 55, The Drive, Hove.

December 6-7.—Watford Camera Club. Hon. Secretary, E. H. Jackson, 100, High Street, Watford.

December 12.—The Scottish Photographic Federation Lantern Slide Competition. Entries to Hon. Secretary, John B. MacLachlan, Blairgowrie.

December 12-20.—Southsea Photographic Society. Hon. Secretary, F. J. Lawton, 5, Pembroke Road, Portsmouth.

December-January.—Wishaw Ph.A. Hon. Secretary, Robert Telfer, 138, Glasgow Road, Wishaw.

January, 1906.—Shettleston Camera Club. Hon. Secretary, Wm. Kitson, Hawthorne Villa, Shettleston.

January 13-February 3, 1906.—The Third Scottish National Salon at Dundee. Hon. Secretary, V. C. Baird, Broughty Ferry. Entries close December 30, 1905.

February 13-27, 1906.—Greenock C.C. Hon. Secretary, W. D. Boyd, 2, Church Place, Greenock.

March, 1906.—Larkhall C.C. Hon. Secretary, Robert Rodger, 26, McNeill Street, Larkhall.

March 3-10, 1906.—South London Photographic Society. Hon. Sec., H. Creighton Beckett, 44, Edith Road, Peckham, S.E.

March 6-20, 1906.—Glasgow Southern Ph.A. Hon. Secretary, W. A. Frame, 28, Bank Street, Hillhead, Glasgow.

April, 1906.—Barrhead Amateur Art Club. Hon. Secretary, R. Murray, 146, Main Street, Barrhead.

April 1, 1906.—Coatbridge Co.-Op. C.C. Hon. Secretary, James Robb, 6, Windsor Terrace, Blauhill, Coatbridge.

FORTHCOMING COMPETITIONS.

September.—Kodak. £400 in prizes for results on Kodak products. Kodak Ltd., 57-61, Clerkenwell Road, London, E.C.

October 1.—Thornton-Pickard. £100 in prizes for photographs taken with Thornton-Pickard cameras or shutters.

October 31.—"Zigo." Cash prizes for prints on "Zigo" self-toning paper. Thos. Illingworth and Co., Limited, Willesden Junction, London, N.W.

November 30.—Royal Photographic Society "Affiliation" Print Competition. Particulars from the Secretary, 66, Russell Square, W.C.

December 30.—Royal Photographic Society "Affiliation" Lecture Competition: (a) Illustrated lecture descriptive of a tour; (b) Illustrated technical lecture. Particulars from the Secretary R.P.S., 66, Russell Square, London, W.C.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

The following applications for patents were made between June 26 and July 1:—

IMPROVED CLIP.—No. 13,222. An improved clip for suspending photographic prints, films, and the like during the operations of developing, washing, and drying. Walter Taylor, 13, Brunswick Square, Camberwell, London.

APPLIANCE FOR HOLDING PRINTS.—No. 13,302. Appliance for holding photographic prints and the like when their backs are being gummed or pasted. Arthur Findlay Sturrock, 41, Reform Street, Dundee.

IMPROVED ENVELOPES.—No. 13,475. Improvements in covers or envelopes for protecting photographic prints and the like. Jamie Lambert, 24, Southampton Buildings, Chancery Lane, E.C.

TIMING DEVELOPMENT.—No. 13,422. Apparatus for timing the development of photographic plates. Mario Fortini, 18, St. Ann's Terrace, Barnes, London.

CAMERA SUPPORT.—No. 13,582. Improved adaptor standard for supporting cameras. Herbert Edward Hickox and Herbert Dawson, 22, Southampton Buildings, Chancery Lane, London.

COMPLETE SPECIFICATIONS ACCEPTED.

Specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

REFLECTOR HAND CAMERAS.—The camera has a mirror and ground glass of the usual type, and to the front of the mirror-carrier is attached a hanging curtain or blind. Just below the carrier this blind has an opening of suitable extent, and below the opening there is enough blind to cover the back of the lens when the carrier has risen to the top of the camera. Instead of the usual cord, a sliding bar, working in the side of the camera, is used to pull down the mirror, which is held by a catch and released by pressure on a stud, which raises the blind, the opening in which allows the light to fall on the plate; the continuation of the rising movement causes the blind to cover the aperture of the lens. An auxiliary shutter is provided, which may be in the form of a wing, and lies flat against the board in front of the mirror, and, when the latter is at the top of the camera, this auxiliary shutter covers the lens aperture and keeps it covered till the mirror is set. The claim is for the method of automatically removing the auxiliary shutter from the lens aperture by the use of a shaped lever actuated by a sliding bar. Samuel Dunseith McKellen, 14, Market Place, Manchester.

CAMERA HOLDING DEVICE.—No. 9,124, 1905. The invention consists of two tripod plates, one of which is secured to the tripod, and the other to the camera; the latter is provided with clip pieces, between which the tripod-plate may be inserted so that the two are at right angles; the purpose being to provide a simple device whereby the camera may be quickly and readily reversed without having to unscrew it from the stand, as is now necessary in the case of cameras not provided with reversing backs. Montague Curtis Rock, Sunnyside, Royal Parade, Chislehurst.

WASHING AND DRYING PRINTS.—No. 10,485, 1905. The invention pertains especially to a machine for washing and drying blue prints, the object being to wash and dry them by the same machine, and to obviate handling the prints. It consists of an upright washing tray, with semi-circular, basin-like bottom, and is provided with a spray pipe. The prints are supported on rods which are held by sprocket chains provided with hooks. After the prints are developed they are carried, by means of the sprocket

chain, on the rods, and thus drain, and are automatically deposited with their rods on the drying brackets. Charles Francis Pease, 172, West Locust Street, Columbus, Ohio, U.S.A.

New Materials.

The "Tabloid" Photographic Outfit. Made by Burroughs, Wellcome, and Co., Snow Hill, London, E.C.

The preparations of Messrs. Burroughs and Wellcome have always been characterised by a delightful compactness and neatness, and their "Tabloid" chemicals have a world-wide reputation for accuracy and quality.

Their "Tabloids" prepared especially for photographic use have proved "just the thing wanted" to make possible the development, etc., of holiday exposures whilst on tour. Apart from this, however, the handy form in which these products are presented, and their reliability and convenience, render them always a desirable adjunct to every dark-room. Solutions of any desired strength can be made up as required without waste of time or material, and the purity and proportions of the chemicals can always be depended on.

A convenient travelling case in which to carry a selection of these tabloid developers, etc., has often occurred to us as being very

desirable, and we were aware that Messrs. Burroughs and Wellcome frequently fitted up special cases to order.

They have now placed upon the market a remarkably complete and neat outfit of photographic chemicals in a strong metal box, which sells at the not unreasonable sum of 5s. The contents of this little "tourists' companion" comprises "Tabloid" chemicals for developing and fixing plates, films, bromide or gaslight papers, also for toning and fixing P.O.P. Indeed, for those with limited space at their disposal, it can easily take the place of any extensive dark-room furnishing, in the shape of bottles of solutions.

To the photographer on a walking or cycling tour, the portability of this little outfit must inevitably appeal. It weighs but little, and the outside measurements of the case, which has rounded corners, and is nicely japanned, are but $4\frac{1}{2}$ by $4\frac{1}{2}$ by 2 in.

The contents of the case include "Tabloid" pyro developer to make 40 oz., "Tabloid" metol-quinol developer to make 44 oz., "Tabloid" combined toner and fixer to make 30 oz., "Tabloid" hypo, and "Tabloid" potassium bromide. This is the standard fitting, and all cases are thus issued unless otherwise ordered. The contents, however, can be varied according to the special needs of the photographer.

The "Marion-Iso" Plate. Made by Marion and Co., Ltd., 23, Soho Square, London.

Messrs. Marion have been so long associated with the manufacture of dry plates, and have placed within the reach of all photographers

series of ordinary dry plates, each member of which possesses excellent and distinctive qualities, that when at length they offer a colour-sensitive plate, the step is one of considerable interest to all those who have already had occasion to respect their manufacturing methods. The new "Marion-Iso" is, first, a plate of notable colour-sensitiveness; and, secondly, a very rapid plate. The conjunction of these two qualities in one emulsion is highly favourable to proper use of an isochromatic plate, for it is desirable in almost every case to employ it behind a yellow screen, and when that course is pursued without unduly prolonging the exposure, the gain to the user is manifest in every phase of practical work. We have subjected the plate to a variety of tests to ascertain its behaviour regarding these two essentials, and the results convinced us of its merits as an orthochromatic plate. It possesses the further advantage of developing quickly, and yielding negatives of good gradation and freedom from fog. Our exposures were developed with pyro, and the results, both of snapshots at 1-250th second (without a screen), and of coloured objects photographed through a medium screen, satisfied us as to the makers' claims in the matters of great speed and colour-sensitiveness.

The following figures, obtained by Mr. C. E. Kenneth Mees, B.Sc., data, certain of which will be found convenient by those who develop by calculation, although it must be observed that the value of inertia of an orthochromatic plate depends on the character of standard light to which the plate is exposed, and the figure obtained with screened acetylene light, as used by Mr. Mees, may differ from those resulting from the use of other lights:—

Inertia (H and D, pyro-soda) 320
 $\gamma \propto$ (density—giving power of plate) 1.70
 (velocity constant of development with standard ferrous oxalate 0 deg. C.), .150.

Time necessary to obtain a standard gradation of 1), six minutes.
 (ratio to blue light, and an index to the latitude of the plate),

Colour-sensitiveness ratio $\frac{\text{blue}}{\text{yellow}} = 4.5$.

On the plates, we have only to add, to recommend them to the discriminative photographer; are sold at the popular price of 1s. per quarter-plate, and 2s. 3d. per dozen half-plate.

Value of Photography to Modern Journalism.—Pictures have always exercised a fascination over the minds of human beings, and in remote ages, when the art of pictorial representation was singularly crude, says the "Daily Mirror." With the development of and in a special manner photography, this fascination has grown more powerful, more irresistible than ever, and modern journalism has not been slow to avail itself of the extraordinary advantages which the camera has placed within its reach. Our contemporary has probably as much experience in this sort of thing as any illustrated paper, and the almost startling rapidity with which events of the day are fully reproduced the next morning in its columns speaks for modern "push" in taking advantage of the latest developments in photographic processes.

The latest number of "The Photo Miniature" (No. 69) deals with "Cutting-Out Papers" and "Kallitype to Date."

PHOTOGRAPHY at Fraserburgh.—A meeting of those interested in their photography and favourable to the formation of a club was held in the Dalrymple Cafe, Fraserburgh, last week. Mr. Lees, Rector of the Academy, presided. It was resolved to form a society, and the view of imparting life to it, it was arranged to hold a lantern exhibition of slides made from members' negatives. A provisional committee to make preliminary arrangements was appointed.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

July.	Name of Society.	Subject.
15.....	Birmingham Photo. Society. ...	Garden Party at Pine Crest, Barnet Green.
15.....	North Middlesex Photo. Soc. ...	Outing to Limpsfield Common.
15.....	Bowes Park and Dis. Ph. Soc. ...	Trip to Wheatthampstead.
15.....	Cricklewood Photo. Society. ...	Outing to Ferivale.
15.....	Manchester Amat. Photo. Soc. ...	Trip to Dane Valley.
15.....	Watford Camera Club ...	Outing to St. Albans and Park Street.
17.....	South London Photo. Society...	Jumble Sale.
17.....	Southampton Camera Club	1. "The Carbon Process." Mr. C. D. Kay. 2. "The Platinum Process." Mr. S. G. Kimber. Demonstrated.
17.....	Bowes Pk. and Dis. Ph. Soc. ...	Competition, Prints of President's Day and River Thames Outings.
19.....	Manchester Amat. Photo. Soc. ...	Mounts and Mounting. Mr. T. L. Cooper.
19.....	North Middlesex Photo. Soc....	"The After-treatment of Negatives" (Intensification, Reduction, &c.). Mr. J. McIntosh.
19.....	Everton Camera Club ...	Half-Day Outing to Dibbinsdale.
19.....	Southport Photographic Society	Trip to Dovedale.
23.....	Everton Camera Club ...	Half-Day Outing to Dibbinsdale.

SHEFFIELD PHOTOGRAPHIC SOCIETY.—The annual meeting of this Society was held on Tuesday last week in the Builders' Institute, Sheffield. The report and balance-sheet were presented. The Council regretted to announce a financial loss on the exhibition and social evening. It appealed to the public to support the coming exhibition more strongly. The new officers were elected as follows:—President, Mr. G. E. E. Noble; Vice-Presidents, Messrs. Charlesworth, Muxlow, and Simmonson; Council, Drs. Helm and Paterson, Messrs. Day, Hill, Gilbert, Jackson, De Silva, Nutt, Seed, Wigfull, and Tomlinson; Treasurer, Mr. T. G. Hibbert; Reporter, Mr. G. D. Harrison; Lanternist, Mr. W. H. Stubbs; Secretary, Mr. J. W. Wright. The result of the monthly competition for the whole year was given, the medals being won by Mr. Simmonson and Dr. Helm.

WOOLWICH PHOTOGRAPHIC SOCIETY.—Mr. G. W. Tapp, having resigned the post of Secretary of this Society, Mr. G. A. Saffron has been appointed in his place. All communications should be addressed to him at 18, Winchester Street, Silvertown, E.

TAMWORTH AND DISTRICT PHOTOGRAPHIC SOCIETY.—The members of this Society had very enjoyable outings on Wednesday and Saturday last week, when visits to Maxstoke were made, the parties being conveyed by brakes.

WEYMOUTH PHOTOGRAPHIC SOCIETY.—The third monthly outing of the members and friends of this Society took place on Wednesday of last week, when Bournemouth was visited.

NORTH MIDDLESEX PHOTOGRAPHIC SOCIETY.—The syllabus of meetings and outings arranged by this Society, to take place between July and September, is to hand, and a great variety of papers and demonstrations are announced, which speaks well for the vitality of the Society during the "off" season.

WATFORD CAMERA CLUB.—The annual exhibition of this Club will be held on Wednesday and Thursday, December 6 and 7 next. There will be the usual classes for members, and also a class for members of Hertfordshire clubs, and an open class.

A PHOTOGRAPHIC society has been established in Shanklin, Isle of Wight, with Mr. Maxey as secretary.

WALSALL AMATEUR PHOTOGRAPHIC SOCIETY.—On Monday last this society held their annual picnic.

"FIGURE STUDIES, Groups, and Genre" are the subjects dealt with in the current number of "The Practical Photographer" (Library Series). The pictorial work of W. Rawlings forms the editorial contribution.

Commercial & Legal Intelligence

PHOTOGRAM, LTD., London, E.C.—Lien registered June 29, for £100 Five per Cent. debenture, part of £1,000; amount previously issued, £882; no trustees; charged on stock-in-trade and goodwill.

WATER Developing (Photographic) Syndicate, Ltd.—Registered June 28. Capital, £2,000 in £1 shares. Object: To adopt an agreement with D. W. Hart, to manufacture, under a certain patent or process, materials for developing, fixing, intensifying, reducing, and chemically dealing with photographic plates, films, and papers, and to carry on the business of photographers, photographic printers, etc., No initial public issue. The first directors are O. Sichel, E. L. White, C. Fitch, and D. W. Hart.

J. DAVENPORT and Company, Limited.—This company has been registered with a capital of £500 in £1 shares. Object, to take over the business of dealer in photographic materials, etc., carried on by F. J. Hearn, at 20, Eldon Street, E.C., as J. Davenport. Registered office, 20, Eldon Street, E.C.

DOUGLAS and Walls, Limited.—This company has been registered with a capital of £2,000 in £1 shares. Object, to adopt an agreement with W. B. Douglas and T. R. Walls, to acquire the business carried on by the vendors at 19, Old Hall Street, and Irwell Chambers, Fazakerley Street, Liverpool, as Douglas and Walls, and to carry on the business of draughtsmen, engraving, and architectural photographers, printers, drawing-office material and general stationers, bookbinders, etc. Registered office, 19, Old Hall Street, Liverpool.

FORESHORE RIGHTS.—At the Weston-super-Mare Police-court last week a case was heard in which much interest was taken by those who vend goods on the sands. Giles Midsummer Williams was summoned by the Urban District Council for erecting a photographic stand and advertising board on the foreshore without obtaining permission. The offence was committed on Whit-Monday. The defence put forward was that defendant's van could not be termed an erection under the bye-laws. The Bench imposed a fine of £4 and allowed the court fees and solicitors' costs. In a similar case against Francis Harris, defendant pleaded guilty, and was ordered to pay a fine of £1.

A PHOTOGRAPHIC Transaction.—At the Wigan County Court, last week, Alphonsus John Smith and Co., photographers, of Moot Hall Chambers, Wigan, were the plaintiffs in an action against James Wright, publican, of Platt Bridge. The claim was for 14s., balance of account for a portrait of the father of defendant's wife. Mr. H. N. Bryan, who represented the defendant's wife, urged that the plaintiffs had taken two years to perform the contract, and did not then supply six cabinet pictures contracted for, although suing for the same. Defendant's wife was called, and she stated that the eyes in the portrait were not properly coloured, although she had given instructions as to the colour they were to be. The Registrar decided that six suitable cabinet pictures should be supplied and brought into court, the defendant thereupon to pay the balance of 14s., with court fees only. The portrait was exhibited in court, but the defendant refused to take it away at the time.

CHARGE Against a Plymouth Man.—At the Dulverton Police-court last week Frederick William Harding, of Plymouth, lately in the employ of Alfred Joseph Hall, photographer, of 95, Fore Street, Exeter, was charged with embezzling 6s., the money of Mr. Hall. According to the prosecutor's evidence, prisoner was a canvasser of orders for enlargements, and also took photographs, on which he was allowed a commission of 20 per cent., in addition to his wages of 10s. per week. Prisoner had taken several photographs of people in and around Dulverton, but had not accounted for the money.

Prisoner pleaded not guilty, contending that, according to a letter written by his master, he was allowed to deduct his commission soon as he received the deposit money, which he had done in this case, and also in one or two others, because money was due to him from Mr. Hall. The Bench dismissed the case from want of sufficient evidence.

SUNDAY Trading.—George Chaplain, photographer, 83, Station Street, Burton, and Robert Widdle, of the same address, were charged on Friday last with an infringement of the Lord's Day Observance Act on the previous Sunday. Detective Smith on Sunday visited the shop occupied by the defendants. Widdle was outside inviting people to have their photographs taken and Chaplain was at work in the shop. A man named Smith, taken back to the shop, admitted that he had paid defendants 6d. for having his photo taken. Chaplain told the Bench that he was no more violating the law than the Corporation who ran the trams. Men were working in the breweries, and he opened his shop to get a living. Defendants were each fined 10s. including costs.

News and Notes.

IN "The Secretary's Letter," the chatty little monthly pamphlet issued by the Scottish Photographic Federation, we note the following good tale. It was during the recent annual excursion of the Federated Societies to Blairgowrie, and Kinclaven Castle was visited. "This said visit led to a very cruel joke on the part of one of the lady Associates, for which we trust she is now sorrowfully penitent. The lady remarked: 'No wonder you Blair photographers are adepts.' Surprise appeared on the faces of the Blair representatives at thus being pitchforked into such a prominent position, but they were less nervous than the rest stuttered out 'How?' The reply came immediately: 'You have been so long at photography.' Again Blair astonished, but one local Associate ventured to suggest that he had heard that Dundee had held one of the first photographic exhibitions, if not the first, in the country, so he did not see why the antique came in as far as Blair was concerned; but, with a smile the lady retorted: 'Ah! but I noticed at Kinclaven that Walter Scott 'took' the Castle in 1297.' It's a mercy we're a' spared!"

WITH the current issue the "British Advertiser" starts a new feature in journalism. An attempt to classify current advertisements under the different heads is being made so that the man who is interested in photography or cycles can see at a glance what other advertisers are saying about cameras or cycles; the man who is interested in coal is the object in life can see what his fellow traders are saying about coal; the grocer what they are saying about grocery, and so on. Such a section should be of great service to the man who is in business it is to compile advertisements. A catch line here, a word there, may give him the clue to a totally distinct and original advertisement. The publishers advise us that they will be pleased to send a specimen copy showing this new feature to all who apply to them mentioning the BRITISH JOURNAL OF PHOTOGRAPHY. Their address is Queen Anne's Chambers, Westminster, S.W.

"THE HOLIDAYS: Where to Stay and What to See" is the title of a bulky volume published by Walter Hill, of 67-71, Southampton Row, London, W.C., at 1s. The contents comprise the seasons of the year, farmhouse, country lodgings, and hotel guides, published by this firm for the six principal English railways: The Great Western, London and North-Western, Midland, Great Northern, Great Central, and Great Eastern. Full particulars of all places of interest that can be reached by these systems are given, and maps and other useful information tend to make the book an exceedingly valuable one.

one contemplating a holiday. Its value to the photographic artist is obvious. The six guides can be obtained separately, price penny each, or free from the respective railway companies' agents or agencies.

PLEASANT departure from the usual lines was made by the Society of Arts last week in holding their annual conversazione in the gardens of the Royal Botanic Society rather than in a hall or gallery. William Abney, F.R.S., Chairman of the Council, supported by a number of the members, received the numerous guests at the entrance to the conservatory.

PHOTOGRAPHIC Survey of Sussex.—Although comparatively little has been heard of it since its inauguration in April of last year, the work of the organisation which was formed to carry out a photographic survey of Sussex has been proceeding very satisfactorily, ample justification for the movement is certainly to be found in results already obtained. Some thirty-eight of the sections into which the county was divided have been taken up by the supporters of the scheme, and up to the present their efforts with the camera have produced well over 600 photographs of objects of historical interest and other subjects of which it is thought advisable to preserve a permanent record. We learn from the "Sussex Daily Express" that to stimulate interest in the work, exhibitions of a selection of the photographs are being organised. The first will be held at Brighton from July 19 to August 9, and will probably be moved to Hastings shortly afterwards.

The printed report of the annual meeting of the National Photographic Record Association has just reached us. We have already referred to this meeting, and now note the complete list of officers for the ensuing year:—President, Sir J. Benjamin Stone, M.P.; Vice-President, the Right Hon. the Earl of Crawford, K.T.; Sir E. Maund, K.C.B., D.C.L.; Sir H. Trueman Wood, M.A.; F. R. Wythe; G. T. Brown; C. E. Fagan; L. Fletcher; H. W. Fincham; Haslam; A. Horsley Hinton; St. John Hope; B. E. Lawrence, Esq.; A. Mackie; G.A.T. Middleton; Dr. H. R. Mill; N. B. Pugh; H. Snowden Ward, Mrs. C. Weed Ward; H. B. Wheatley, Esq.; hon. treasurer, A. Graham, F.S.A.; hon. secretary, George Pell.

PHOTOGRAPHIC Survey of Essex.—By invitation of Lady Warwick, members of the Essex Field Club held a meeting at Easton Lodge on Saturday last for the purpose of inaugurating a photographic and archival survey and record of Essex. Lady Warwick took the members over her extensive gardens and entertained them at luncheon. The meeting was afterwards held, under the presidency of Mr. David Ward. Mr. Miller Christy explained that the object of the survey was to make a permanent collection of photographs and other records of objects of interest, also maps, plans, and other documents in order to give a comprehensive survey and record of all that was valuable and representative of the county of Essex. These pictures and documents would be filed at the museum of the Essex Field Club at West Ham, where they would be open to the inspection of local antiquarians, pressmen, and all who were interested in the history of the county. He appealed to all the organised photographic societies of Essex, as well as unattached photographers, to assist the Committee in their work. We hope that not only will this attention be well responded to, but that the example set forth will be followed in many other counties. Old country features are being rapidly swept away, particularly near London and the great manufacturing centres of the North, that unless they are now recorded in photographs the memory of them will soon entirely disappear. We have lost so much of the picturesque that we cannot afford to let more of it vanish without making records which shall be accessible to all.

Correspondence.

ADVERTISING AND THE PROFESSIONAL PHOTOGRAPHER.

To the Editors.

Gentlemen,—In your issue for April 7 Mr. W. J. Casey suggested to professional photographers that "The announcements of births in the local newspapers be filed; about two or three months later a letter might be sent suggesting that Mrs. So-and-So may possibly be requiring some photographs, etc." Although only one of your amateur readers, I do not disdain to read what you publish for the benefit of my professional brethren.

I was, therefore, immensely amused when my wife handed me one morning last week the following letter, written, and neither type-written nor printed:—

"Dear Madame,—Your son will be two years of age on Tuesday, the 11th inst., and if you will bring him to our studios we shall have much pleasure in photographing him free of charge.

"Awaiting the favour of an appointment, which is necessitated by the very large number of children that are brought to us, we remain, yours, etc."

I may state that this letter emanates from a studio not 100 miles from Bond Street.

Is this the result of Mr. Casey's good advice, or has he got the idea from this firm? I do not see, on reference, that your contributor suggested the "free-of-charge" dodge, but I venture to bring it to the notice of your readers, as it may be of use to some professional photographer as a hint.—Yours faithfully,

GEO. TERRY, Amateur.

London, E.C.

P.S.—My wife said that she did not see why she should travel thirty miles to get the child photographed for nothing, when I did it every month, and did it, she was quite sure, as well as they or anybody else could do it, for nothing. This, of course, is merely wifely pride.

To the Editors.

Gentlemen,—There can be no doubt that the series of practical articles which appeared recently in the BRITISH JOURNAL on advertising for photographers have been of considerable service to many professionals, including myself, and it was with particular pleasure I perused the admirably produced pamphlet by Mr. F. W. Speaight to which you referred last week. Quite apart from the value of the suggestion made by Mr. Speaight for the improvement of the approach to the Marble Arch, one cannot but admire the splendid subtlety apparent in the absolute suppression of any reference to the author's identity beyond the invitation to inspect the original plans in the galleries at 157, New Bond Street, London, W. This, coupled with the princely offer of 500 guineas towards the scheme, must undoubtedly set tongues a-wagging; and the question that naturally first arises in the minds of the uninformed is "Who is Speaight?"

Very little investigation soon establishes the photographer's identity, and no finer form of discreet advertising could possibly be conceived. I hope, however, I am not giving Mr. Speaight credit for a purpose that he did not contemplate when drafting his admirable scheme for the improvement of this part of one of London's thoroughfares, but in any case the instance can be taken to heart by every photographer as an example of the advertisement de luxe.—Yours faithfully,

PUSHING PRO.

Nottingham, July 8.

Answers to Correspondents.

- * All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C. Inattention to this ensures delay.
- * Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- * Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.
- * For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

John Weir, Burn Cottage, Moffat, N.B. Two Photographs of "The Smithy," at Wamphray, County of Dumfriess.

Lacy & Clay, South Street, Calster, Lincs. Photograph of Group of "The Committee of the United Friendly Societies of Calster, Lincolnshire."

Charles Arthur Harris, Wesley House, Merthyr Tydfil. Photograph of Reading of Charter of Incorporation at the Town Hall, Merthyr.

BLUE PRINTING.—What are the possibilities of a photo-printing office?

by this I mean where the usual blue prints, etc., are made and where tracings from engineers' and architects' drawings could be combined. I am at present a draughtsman, and quick at tracings, and am also an amateur photographer of some years' experience, having won several prizes in open competition, and have made small blue prints by sunlight for my own amusement. As, however, I see very little prospect beyond being a draughtsman all my life, I feel that I should like to learn the photo-printing business, with a view, after some years' experience, of forming a business of my own, and I shall esteem it a great favour if you could tell me if it is a business that is likely to increase, the best means of obtaining a situation in London, and the salary I could ask? If you are unable to answer these questions I should be very grateful if you could put me in communication with some one on the various points asked.—A. H.

We cannot hold out much prospect. Surely you, as a draughtsman, know the sort of wages paid to blue-printers. Work of this character is now so simplified by the modern papers that a boy can be set to make copies. Possibly in manufacturing centres in the North of England there may be openings for a business of the kind, and such businesses have occasionally been advertised in our columns.

DARK SLIDES—I should be very much obliged if you will put me right regarding my dark slides. I have three double-backs, and I find that the linen where the door of the slide folds back has perished. I must replace the linen, but I am at a loss to know how it is stuck on and what to re-do the slide with to render a dead black?—READER.

Black linen or silesia can be obtained from almost any draper or photographic dealers, and ordinary glue or a ready-made adhesive like secotone would answer to make it adhere. As regards blacking, if black linen is used, this would not be required, but if ordinary unbleached calico were used then a little drop black, rubbed up with ordinary negative varnish and rubbed in with a fairly stiff brush, would be quite efficient. Or some water-soluble nigrosine black mixed with gum would answer the same purpose.

STRIPPING—What is the best method of stripping films as an aid to carbon printing?—CARMOAL.

Coat the negative fairly thickly with ordinary enamel varnish

or celluloid dissolved in amyl acetate and acetone, allow thoroughly dry, and then immerse in

Hydrofluoric acid	60 minims.
Methylated spirit	1 oz.
Water	2 ozs.

for a few minutes, when the film will soon lift at the corner and may be coaxed off and washed in clean water and dry. Another method which obviates the use of liquid hydrofluoric acid is to harden the negative by ten minutes' soaking in 10 per cent. solution of formaline, then immerse in a 5 per cent. solution of sodium fluoride, and rinse and transfer to a 5 per cent. solution of hydrochloric acid, and then wash dry. The films are very thin, and we think it better to strengthen them by giving two coats of the celluloid varnish mentioned above, the strength of celluloid being about 8 grains to the ounce of solvents.

COPYRIGHT QUERY.—I have a negative of the deck of the old Victoria flagship showing Nelson falling in the battle of Trafalgar with his men round him. I took it from an oil painting made some twenty years ago. There is no sign of copyright, or even anybody's name on the painting. I have had the negative in my possession now eight months, and what I want to know can I make prints from it for postcards?—PROFESSIONAL PHOTOGRAPHER.

We cannot say if there is an existing copyright in the picture or not. If the painter is still alive there would be. So there would be if he has not been dead seven years. Copyright endures during the lifetime of the artist and for seven years after his death. Your best way will be to ascertain if the painter is still alive, or, if not, when he died. If you use the negative without ascertaining that you will have to take the risk of an action for infringement of copyright.

* Many Answers to Correspondents, Reviews, and Notices are unavoidably held over.

A MEETING was held last week in one of the Committee Rooms of the House of Commons to consider whether increased State aid might not be secured for and keener interest aroused in the National Physical Laboratory at Teddington. Mr. R. B. Haldane, K.C., M.P., was in the chair, and Dr. Glazebrook and Mr. Chamberlain made speech on the present position of the laboratory and the necessity for State aid. It was finally resolved that a memorial should be presented to the Chancellor of the Exchequer asking for such additional aid.

PRINCE ARISUGAWA, our recent Japanese visitor, is, according to the "Manchester Daily Guardian," an expert photographer. At the launching of the Japanese battleship Katori, at Barrow-in-Furness by the Princess, the Prince advanced to the front of the platform camera in hand, and took some snapshots of the scene with much care and deliberation. If one might judge from the number of cameras carried by the Japanese who accompanied the Imperial couple, amateur photography would appear to be a favourable amusement with this interesting people. Several of the escort of officers of the Japanese Navy, and even some of the Japanese ladies, were provided with cameras, which they used frequently.

* NOTICE TO ADVERTISERS.—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

EX CATHEDRA.

Convention. The twentieth meeting of the Photographic Convention of the United Kingdom has come and gone, and everybody appears to be thoroughly enjoyed themselves and benefited by being new and cementing old friendships. Dublin could have been more hospitable, which is the same thing saying that no place could have made the Convention welcome. Next year's meeting is to be at Southampton—a centre with facilities for landscape photography good as can be desired. At the same time it is to be decided that the Convention Council will take a more serious view of its responsibilities, in inviting scientific technical communications, than it has lately done. We believe we are only re-echoing the views strongly held by a number of those who have the future prosperity of the Convention at heart when we say that the Council should not afford to lose a single opportunity of encouraging communication of original papers. We are told that evening audiences are not attracted by technical and scientific papers, but we reply that the audience reached by such communications are many times larger than that which listens to the spoken paper. It is by such publicity to the photographic community that the Convention must preserve its prestige and keep itself before the photographic world. It is to be hoped that the newly elected Council will keep this fact clearly before it.

Convention up. With this issue we present a reproduction of the photograph of members of the Convention, taken by Mr. Alfred Shorter. The names of those appearing in it were supplied by the sitters themselves, and it was thought in distributing a series of tickets among them to identify each one. This plan, for certain reasons which no doubt

are obvious to those who were present, broke down, but that fact has suggested a method which seems infallible, and may be useful when the name of each person in a large group is required. A ticket with a boldly printed number thereon is given to each person, with the request to write his name on the back. After the usual exposure the members of the group are requested to display the numbered side of the cards and a second plate exposed. From the negative so obtained each person can be identified on reference to the cards, which are collected on the group breaking up.

* * *
Copyright in Portraits. The case of special interest in which Mr. William Crooke, the Edinburgh photographer, has prominently figured is reported in another column, and will be seen to centre mainly on facts and evidence. But there is one part of the judgment of Lord Ardwall that may take some not a little by surprise. He said he "had come without any difficulty to the conclusion that the truth of the matter was the sitting at which the photograph was taken was a sitting for Mr. Shorter, and that he was *prima facie* entitled to all the portraits taken at that sitting, unless it could be shown that Sir Henry Irving and Mr. Shorter agreed to any of the photographs becoming the copyright of the photographer. With regard to the copyright in question, his lordship was of opinion that that had not been proved." The decision in this case has an important bearing, if it is to be taken as a precept, when a sitter—say a celebrity—is brought by a third party to a photographer to have a portrait taken for a special purpose, or if he comes on his own account—say, for example, a clergyman comes to have some portraits taken for private use, and the photographer asks permission, and it is accorded, to take one or two more pictures for himself for publication. According to this ruling, it seems to us, he will have no copyright in them unless an agreement is made at the time, which, according to the Act, must be in writing, that the copyright in these pictures is to be the property of the photographer, otherwise it will belong to the third party, or the sitter, as the case may be. It will be of no use for the photographer in these circumstances to register the copyright in them. Not only must there be a written agreement but it would be advisable that it should also bear a sixpenny stamp when such an agreement is made; the photographer should particularly describe in it the pictures he has taken for himself so that there would be no after dispute as to whom the copyright in them belongs. We call special attention to this case because it is the first, so far as we are aware, of the kind that has come before a court of law in which a similar ruling has been given.

The "Free Sitting."

It is not surprising to find the "Daily Chronicle" considerably elated over the judgment in the Crooke-Irving case, and eager to hold it up as a warning to public men in their relations with photographers. In an interview with a "Chronicle" representative, Mr. Clement Shorter expresses himself very strongly on the point at issue. It is not difficult to understand the desire, on the part of an editor of an illustrated journal, to see copyrights of celebrities' portraits in the hands of the persons themselves, but it is doubtful whether an illustrated journal would be any better off under the desired state of things. It would obtain certain portraits gratuitously, and it would have to pay for others. Others, again, it would not be able to obtain. The photographers supply the demand in the illustrated press for portraits of celebrities, and we can imagine how much more difficult it would be, in many cases, for a paper to get a portrait from the individual himself. Society people do not look on the photographer as a "robber"—the word is Mr. Shorter's—because he undertakes, as more than one West End photographer does, to control the reproduction of their portraits in the papers. They are glad to authorise him to do so and to draw his fees for the purpose, and it may be questioned if the greater difficulties of dealing with principals will compensate art editors for their economy in photographers' reproduction fees. But on the other hand we would not lose sight of the unfavourable light which the "free sitting" sheds on the profession of photography. For practical purposes, the "free sitting" is an admission that the photographer cannot depend on the supply of portraits to make his business remunerative, but must make what he can from the "copyright," which he attaches to himself by the "free sitting." In a different way the practice lowers photography as does the production of cabinets and other prints, turned out half automatically at disgraceful prices. It is our profound conviction that the policy of those who desire the welfare of the photographic profession should be the sale of good portraits at a good price. Only in that way is it possible to take a firm stand towards the public, to prove to the customer that the work is worth the price asked for it, and to build a business on solid foundations. We know that there are businesses to which the "free sitting" is the very breath of life, but that condition has come about from circumstances external to photography, and various things, such as a change in the law of photographic copyright, might be the pricking of the bubble. Perhaps the recent Scottish case will serve to remind photographers of the flimsy nature which business founded on "free sittings" may acquire under circumstances which the photographer is powerless to control.

* * *

The P.P.A. Circular.

The Professional Photographers' Association has established itself by another bond still more firmly in the public and private service which it is rendering to professional photographers. It has now issued the first number of a "Circular" which will be distributed only among its members, and will professedly deal with matters which are more fitly communicated only to members of the Association. To our thinking, No. 1 contains very little that demands such semi-privacy, and we cannot conceive that the Association or any of its members would be worse off if the profession at large read how its president, Mr. T. C. Turner, fought the "Free Portrait" frauds in Hull. Therefore, the opportunity of perusing the official sheet would be an additional inducement for photographers to join the ranks of the Association. The *raison d'être* of the circular is, of course, to keep the members, who are spread all over the country, and who naturally cannot

be gathered together, to have by word of mouth what the Association and the committee on their behalf are doing in touch with the proceedings, and naturally the bulk of the matter concerns the domestic affairs of the Association. The "Copyright Notes," however, touch upon matters of such general interest, and are full of so much practical information, and written in such a commendably broad-minded spirit, that the circular would attract fresh members to the Association, if it was generally disseminated amongst the profession.

* * *

Courtesy.

We cannot, in fairness to the Association, quote much from a publication that is issued as a confidential communication to its members, but the following paragraph seems of such general applicability that we hope that beyond being instructive to many of our correspondents in the professional ranks who consult us upon matters to which the hint applies, it will lead to the desire to join an association which so carefully looks after the interests of professional photographers in copyright and other matters: "It is a great mistake to jump at the conclusion that the infringement of a copyright is necessarily a work of malice or an attempt to deprive the owner of something he is entitled to. Every one, of course, is presumed to be acquainted with our laws, and no one is absolved from the consequence of his ignorance; but, infringements very often occur merely through inadvertence, misunderstanding, or ignorance. When an infringement is discovered, the most business-like and the most dignified way to treat it is to assume that it occurred from one of those causes, and that when it is pointed out, the complaint will be met in a reasonable way. Regard it as merely a business matter that requires adjustment, and as it is a delicate matter of diplomacy use the most courteous language, and do not make any demand, but ask what the other side is prepared to offer you in compensation for your injury."

* * *

"Tabloids" and Science.

The reproach that has on occasion been levelled at British scientific research when compared with the methods of our Teutonic neighbours and other nations, must surely be removed so far as one English firm is concerned. We refer to the splendid work undertaken quietly and without ostentation, but nevertheless far-reaching in effect, by Messrs. Burroughs Wellcome and Co. Their place in the world of pharmacy and medicine, to say nothing of photography, was well indicated by the remarks made by speakers at the firm's quarter-century commemoration at Dartford, on Saturday last. The members of the Society of Chemical Industry were the special guests on that occasion, and as the society includes in its ranks most of the leading research chemists and business men engaged in chemical industries and in industries requiring the aid of expert technical chemists throughout the British Empire and America, the voice of the president (W. H. Nicholls, M.S. LL.D., D.Sc.) can be regarded as authoritative. He praised not only the commercial work of this great firm and the philanthropic endeavours of Mr. Wellcome in making his vast army of employees a remarkable and ideal happy family, but he more particularly referred in terms of admiration to the other branches of the firm's work, notably the Wellcome Physiological Research Laboratories at Brockwell Hall, Herne Hill (under the direction of Dr. Walter Dowson), and the Wellcome Chemical Research Laboratories at King Street, E.C. (under the direction of Dr. Frederick B. Power). These laboratories are quite distinct and separate institutions to the "Tabloid" manufacturing business, and judging from the sentiments also voiced by such eminent men as Professor H. E. Armstrong, Ph.D., L.C.D., F.R.S., Sir James Dick, K.C.B., M.R.C.P.

on. Surgeon to the King), the president of the Pharmaceutical Society of Great Britain (R. A. Robinson, J.P., F.C.), and A. Gordon Salamon, A.R.S.M., F.I.C., F.C.S., labours of Mr Wellcome in scientific research is being everdly appreciated by pharmacists and medical men world over.

PRINTING PROCESSES.—VIII.

ALBUMEN PAPER.

The fifth article (see page 462 ante) the method was dealt of printing on albumenised paper, in which the albumen was largely diluted with water, as it was when less say prints than those now in vogue were the rule. At present time the albumen is used undiluted, and even concentrated in order to supply the demand for a highly albumenised paper. We surmise that the reader is not desirous of albumenising his own paper, but will prefer to purchase the commercial article as now on the market. However, should he desire to do so, we may tell him that the albumen is to be purchased by the gallon at the whole-egg merchants, who break the eggs and sell the whites and yolks separately. The latter are, to an extent, sold as strychnine, but we are informed that the greater bulk of the glove-making districts, where they are in large demand for dressing kid leather. Albumen papers are like P.O.P.s, with different tints, or white, and it is a matter of taste which is used.

Some samples of paper have a very fetid and offensive odour, owing to decomposed albumen being employed in its preparation. This is done because this fermented, decomposed, albumen yields a higher gloss and is easier to apply than fresh albumen. It would occur to some that prints made on a paper of this kind would be of a stable character. The supposition, however, is borne out by facts. We happen to have by us some prints that were made on a most fetid paper, more than thirty years ago, and they are now as good as some that were made on paper with fresh albumen at about the same time. Albumen paper is now supplied both sensitised and unsensitised, and we shall deal with the former first, as there are many photographers who still prefer to sensitise their own paper—notwithstanding the fact that it involves extra trouble—because they aver that they get better results upon it than they can upon the unsensitised.

The makers of albumenised papers do not tell us the quantity they use, or the proportion of it they employ, and the user does not, from this source, learn the proper strength of silver bath to employ. It is generally understood that the silver bath should contain, in grains per ounce, six to eight times that of the chloride in the solution, supposing this be the chloride of ammonium, which is the one most generally employed. Thus, if the strength of chloride be eight grains to the ounce the strength of silver bath would be, say, sixty grains to the ounce of water. But some papers contain less silver than that, consequently a weaker bath will suffice. With the papers now on the market the makers usually issue a formula for the sensitising bath and the user will do well to work according to that whatever the strength given may be. In times past different additions to the silver bath were suggested—nitrate of potash was one, and it was said that with them the proportion of silver could be materially reduced, but the suggestions did not meet with much favour with professional photographers. A plain solution of nitrate of silver is what is most universally used, and the strength generally employed is sixty grains to the ounce, or whatever the makers specially recommend.

We shall here assume that the sixty grain bath is to be

used. It is well to make up a good quantity of the solution at a time. In a Winchester quart bottle put ten and a half ounces of nitrate of silver and add two quarts of distilled water, and dissolve. This will give us a bath of the desired strength. Three or four drops of nitric acid are then added, as that confers greater keeping qualities on the paper. The solution is then filtered through paper into a dish, and the paper floated upon it for from two to three minutes, according to temperature. There are different ways of placing the paper on the bath, but here is one of the best: Take the paper by two diagonal corners and bend it to a bow. One corner is then placed on the solution and the rest of the sheet gently lowered upon it so as to avoid air bells. After resting a few seconds a corner is raised to see if any air is imprisoned, and the paper allowed to remain the requisite time. It is then removed and pinned, with a black pin, by a corner to a line to dry. After hanging a few minutes to drain the drying may be completed before a fire, that is, if the paper is wanted in a hurry. In removing the paper from the bath it should be taken off slowly and with a somewhat dragging motion, as then there will be very little superfluous solution left to drain off. Sometimes, when the paper is first put on the bath, it will have a tendency to curl away from it, particularly if it be very dry. This may be remedied by gently breathing on the back, when it will at once lie flat.

On the silver bath two changes take place in the paper. The one is that the chloride—say that of ammonium—is converted by double decomposition into the sensitive chloride of silver, and the albumen, which was previously soluble in water, is rendered insoluble. When dry the paper is ready for printing. In America it is very customary, after the paper is dry, to fume it with ammonia. The paper is suspended in a cupboard, or box, at the bottom of which is a dish containing liquor ammonia, where it is allowed to remain ten or fifteen minutes before it is printed. This practice, however, has not found much favour in this country. By use the bath becomes weaker as the paper appropriates to itself a larger proportion of the nitrate of silver than it does of the water. Therefore it has to be strengthened from time to time, either by the addition of a stronger solution or of crystals of nitrate of silver. After half-a-dozen or so sheets have been floated the upper portion of the solution will have become weakened, therefore it should be stirred up by passing a glass plate backward and forward through it two or three times, or by rocking the dish. If the solution is allowed to stand for an hour or two in the dish, after paper has been floated, a scum will have formed upon the surface. This must be skimmed off with a strip of blotting paper, otherwise the next sheet floated will have a stained or marbled appearance and be useless.

At the photographic dealers small hydrometers called "argentometers" are sold, which indicate the strength of the silver in grains per ounce. Theoretically they do not do that accurately by reason of the nitrate of ammonia—formed by the double decomposition—dissolving out in the bath, but they are good enough for all practical purposes. By use the solution becomes discoloured, and if used in that state it would tint the paper. It can, however, be decolorised in different ways. The most general is to add to the stock bottle a little kaolin. The solution is then well shaken up and allowed to stand till the next day, when the clear and colourless liquid is decanted and filtered through paper. The same filter may be used many times if the first lot that passes through is returned for a second filtration; thus there will be a saving of filter papers as well as silver. The next article will deal with the printing and toning of albumen paper.

INDIVIDUALISM.

THESE are days of competition, when the position of the very foremost professionals is assailed. Men who ten or twenty years ago considered themselves above competition are now compelled to compete in the race for position. This competition has been the making of some photographers; others, alas, have fallen by the way.

The Bane of Cheapness.

Workers who a decade ago were considered clever, can to-day only rank as good ordinary photographers; they can turn out good ordinary work, but so can thousands of others, with the difference that the others who have not heavy expenses and large establishments to keep up can do their work at cheaper rates. In these days of cheapness, if a patron can get work of an equal quality at a lower rate, he will not pay a bigger price for the pleasure of seeing some well-known photographer's name at the foot of his print, and thus these same workers who ten years ago did good ordinary work and made it pay, are badly off to-day, whilst those who go in for a specialty and do work out of the common are sure of retaining their old patrons and adding considerably to them as the years roll on.

The Difference in Photographs.

The "middle" class photographer has improved his work by leaps and bounds, and there is no longer the wide chasm between their work and that of the front-rank man. They can both take and finish photographs with skill, but the one stamps his work with individualism, and the other turns out good ordinary work. The labour is nearly the same in each case—the one is little more costly to work than the other—but the difference in the payment is a wider difference than of old. Take the work of the front-rank man (to name one or two when so many are worthy of mention would be unfair); you can tell at a glance who the artist is. "Oh, that is So-and-so's style," you exclaim; but do you stop to think why you recognise it as such? You did not require to look at the name at the foot to trace the artist; his work tells you. It is, in fact, individualistic. The same mannerisms run through the whole of his work; a certain pose, lighting, style of background or of mounting, colour of print, or perhaps a bit of each. No matter what it is, it is something out of the ordinary, and that is the whole secret.

There was never a time in the history of photography when good work was more in demand, for the public have been educated up to a higher standard than would have satisfied them ten years ago. They don't want the common or garden photograph, but an artistic effort. The old album, with its places for C.D.V. and cabinets has been carefully stored in the lumber-room for the benefit of future generations, who will no doubt derive considerable amusement from it. There is no royal road to individualism, though it can be attained by anyone possessing artistic feeling if they are willing to study, and it is a study that will repay the professional photographer a hundredfold. In fact, I go so far as to say that no professional photographer can get on without giving this matter considerable thought.

The Study of Great Portraits.

It would be foolish to point out the defect without giving the means of remedy. This will not be a difficult task. My advice is to go to the nearest art gallery and study the old masters; take one of these for your model, and see as many of his works as possible. They will all vary in some particular, but the same individualism will run through all. I go so far as to recommend you to have your backgrounds painted in a similar style to those used by the artist. You may only have everyday sitters to photograph, but that need not deter

you from the work, for you must remember that these subjects were everyday people when the portraits were painted. Follow your artist closely for a little while, and you then get the style of work, after which you will be able to put your own individualism into your work, thus making your work after the school of Gainsborough, Vandyke, Reynolds etc., but from a photographic standpoint of your own.

A high-class photographer who has made a moderate fortune out of the work gave me the following information in reply to my request as to how he had made his business so successful in so few years, in face of the bad times and great competition. "I made up my mind," said he, "that there was no room for a photographer who could only turn out ordinary work at ordinary prices, so I decided to do something out of the common, and charge my own price. But what should I do and how should I do it? Happy thought! why not go to London and see how the old masters worked? I spent a week in the National Portrait Gallery, the National Art Gallery, the Academy, Tate, etc. This was my first step upwards, and since that week I have spent many happy hours in the same places, and have always returned home with new ideas and higher aspirations. Considering I worked my business from midgets at 4s. 6d. per dozen to its present position, I consider my holidays in the London art galleries my cheapest outings and greatest help."

I can only recommend my readers to give this advice a trial, and then I feel sure we shall hear less of bad times and of that very useful and necessary competition that is so much to the front at present. What is wanted is better work. There is plenty of room on top, but a man will never get there if he keeps in that same old rut of ten years ago. That particular rut leads down hill, and it is time to get out of it.

I will summarise my remarks with a few hints of what to do and what not to do.

Backgrounds.

The ordinary interior and exterior are dead. They have done their duty; let them rest in peace. Go in for a special background painted to your own ideas, and use as few stage accessories as possible. Change the whole of your background as often as means will allow. Your clients do not want photographs of balustrades, steps, or pedestals, but of themselves. On the other hand, graduated backgrounds may be good for vignettes, but do not use them for everything. If your position will not run to a specially painted background, try a plain white or black one with a continuous foreground; but have something out of the ordinary.

Lighting must follow the background. If you are having your background painted after Gainsborough, follow his lighting also. I have seen work by front-rank men with the sitters beautifully lighted, but in absolute contradiction to the background, thus spoiling the whole effect.

The Printing Process.

Do not use the easiest because it is the easiest, but use one that shows off your work to the best advantage. Every good photographer should be able to make a first-class print in sepia and black platinotype and in carbon. Do not let yourself too much in the hands of your printer. Not only should you be able to tell when a print is well done, but you should be able to show your printer how to do it. The printing room is just as important as the studio, but how many photographers give it the attention it should have? There is as much money made in the printing-room as in the studio, but through want of attention many a photographer is ruined by the printer's bad work.

Mounting.

carry your individualism to your mount. Again try to get something out of the ordinary. Your mount maker will only too pleased to carry out any idea you may have. If you do not wish to go to the expense of a special mount, make a print on thick paper, mask out a margin, and put in a date mark by means of a piece of zinc and a letter press. You have then a high-class mount ready made. Do not expect that by following my advice you will jump to the forefront of the photographic profession and increase

your business by leaps and bounds. But by showing better work than the ordinary man your showcases will attract more attention, and business will follow. It may come slowly, but it will come; of that I am certain—and with better prices. Do not grumble about competition, but advance the quality of your work, and, once more, remember there is plenty of room on top for the man who can do something out of the ordinary, or, in other words, for the man who can stamp his work with individualism.

W. WALLINGTON.

THE WEEK IN HISTORY.

The Reflex Camera in 1861.

is forty-three years ago to-day since Thomas Sutton patented the pattern of camera which we recognise to-day as the last word in camera construction. His "improved camera" was for taking photographic portraits of instantaneous pictures, and he used the reflector as a shutter—raising and lowering it to make the exposure as well as to give him an erect image of the object on the ground glass, which he let into the top of the camera. He dwells on the advantageous fact that "the operator is enabled to focus the lens, and afterwards expose the sensitive plate at the proper instant," and he points out that for the clarity of the image on plate and focussing screen it is necessary that the respective planes of the focussing screen, the sensitive plate, and the reflecting surface of the reflector should be on one common centre of convergence, and that the plane of the reflecting surface should bisect the angle formed by the sensitive plate and the focussing screen. His "instantaneous" of course, meant a very different thing from that of the modern reflex camera, with its focal-plane shutter, for his patent (No. 2,073, 1861) provided for no shutter, and his test exposure must therefore have been as much as a quarter or an eighth of a second.

The Burgess Gelatine Emulsion.

Last week I reproduced the first advertisement of a gelatine emulsion, and I may find space here for the comments of THE BRITISH JOURNAL OF PHOTOGRAPHY upon it the following week. In the issue of July 25, 1873, an editorial reports:—"We may say there is no collodion in the matter at all. Instead of collodion, a colloidal substance, without doubt, is used, with probably some admixture of albumen, is used, and

the sensitive material, which we assume to be bromide of silver, is introduced in such a way as to necessitate no washing. The method of preparing the plate is extremely simple. The emulsion, after being slightly warmed, is merely poured upon the glass, is allowed to dry, and—that is all. The plate is then ready either for immediate exposure, or for storing away. . . . On application of the developer (alkaline pyro) the picture rapidly made its appearance, every detail being visible. These details were afterwards brought to a great degree of intensity by the application of the usual acid pyro and silver. . . . We congratulate Mr. Burgess, who is an artist rather than a photographer, upon the bold and highly successful step he has taken to escape altogether from the trammels of collodion."

Bromide Paper.

Sir J. W. Swan's association with the carbon process ("The Week in History," February 24) is liable to overshadow his early appreciation of gelatino-bromide emulsion as a substance for positive printing. His patent for this purpose dates back some twenty-six years, and claimed protection for an emulsion of silver bromide, not only in gelatine, but in albumen—in each case for purposes of printing from negatives. The process set forth in his specification (No. 2,968, 1879) is that widely adopted by bromide printers, viz., development with ferrous oxalate, and mention is even made of ". . . printing at a uniform and rapid rate; the sensitive paper may be used in long bands, and by means of automatic mechanism may be moved on step by step periodically through a space equal to the width or length of the print, the negative being screened from light during the movement." HISTORICUS.

CURRENT METHODS OF PHOTO-ENGRAVING.

On the occasion of the visit of Mr. William Gamble, editor of "Process Work" and "Penrose's Pictorial Annual," to New York, S. H. Horgan, editor of the Process Engraving Department of the "Inland Printer" and manager of the art department of the New York "Tribune," with characteristic enterprise, arranged for Gamble to deliver an address at the Beethoven Hall before the engravers of New York. A representative gathering (including Mr. F. E. Ives and other well-known men in photographic and engraving circles) was present to hear Mr. Gamble, and by courtesy of Mr. Horgan we give a portion of his address, as it conveniently presents the present practice of process work in this country in contrast with that in America. After discussing some points of status and accessories, Mr. Gamble comes to technique.

Reversal by Prism or Stripping.

At the point where we differ from you is in the use of a prism or instead of stripping the negatives. We consider, rightly or wrongly, that stripping does not really save much time. By revers-

ing the negatives with the prism they are passed on as fast as they are made to the metal printer, and he in turn can keep the etchers going, instead of having to wait for a 'flat' of stripped negatives to be prepared. We are, however, beginning to use stripping more extensively for line zinc etching, and we also use it for combination printing—that is, combined line and half-tone—of which we do a great deal. Sometimes, however, we do this work by making two prints on the metal, sensitising it again after the half-tone print has had its first biting. Mirrors are sometimes used instead of prisms for cheapness sake, and when in best condition do not cut off so much light, but they soon deteriorate, and are really dearer in the end, as they have to be frequently resilvered.

Wet v. Dry Plate.

"Of course, we use wet collodion almost entirely, pretty much in the same way as you do, except that we mostly buy the collodion ready made. We intensify line negatives with lead instead of copper and silver. Several firms are now doing all their best half-tone work,

especially wash drawings and difficult photographic originals, with collodion emulsion, and find it gives a better result—softer, fuller in detail, and with better gradation. It is probable that in time collodion emulsion will largely displace wet collodion for the best black-and-white work.

"Attempts have been made to use gelatine dry plates and some firms make it a boast that they use nothing else. But it is generally believed that the metal printer and etcher have to make good the deficiencies of the negatives.

The Enamel Process.

"The fish-glue or enamel process which we imported from America is now in universal use in England for half-tone work on copper and also to some extent on hard zinc. For coarse newspaper half-tones we use the albumen bichromate sensitiser, which we also use for line-work. We print pretty much as you do, but we do not use much the four-way powdering method. Our etchers seem to prefer a combination of the old and the new processes. They ink up with a lithographic roller and soft etching-ink and use the red powder as a top, melting the ink down the sides of the lines. A few, however, are following strictly the American method, and I think the tendency is to use it more and more.

"Cold" and "Dry" Enamel.

"We have had a process exploited in Europe under the name of 'Cold Enamel' process, so called because it was claimed that it did not require burning-in. The print was made with fish glue and washed out as usual. It was also slightly heated to a light yellow colour, just sufficient to discharge the dye. Then it was etched in a bath of alcohol and nitric acid. The alcohol prevented the film becoming soft.

"You have all heard also, no doubt, of the 'Dry Enamel' process. A few firms are using it in Europe and it is generally understood that the print is made with a solution consisting of sugar candy and white of eggs, with water and bichromate, and perhaps a little chromic acid. The addition of the sugar candy causes the film to become hygroscopic—that is to say, it takes up moisture from the air. While in this tacky state a powder is brushed over it and adheres in proportion to the action of the light. Various things have been used for this powder, but I think the most likely chemical is anhydrous carbonate of soda, which is a dry white powder.

The "Blue" Process.

"We used to hear a good deal of what was called the 'Blue' process. This consisted in printing the image with albumen bichromate the same as for line etching, but instead of inking it, the plate was flowed over with a bituminous varnish, the solvents of which were ether and chloroform, so proportioned that a slightly porous film was yielded, and this could be developed with water the same as the inked print. When developed, the plate was heated and the porous structure was closed up. The plate would stand a first bite without further treatment and could afterwards be rolled up.

Etching Methods.

"In the matter of etching there is not much to say. Copper etching we usually do with perchloride of iron, but we have lately found a much purer and better variety of this salt than the commercial kind, and it is sold under the name of 'Persal.' Some firms are using nitrous acid for deep etching linework on copper, but the fumes are not very pleasant, and the etching is generally done out of doors. For zinc etching there has been used a mordant compounded with pyroligneous acid and sal ammoniac with, I believe, a little nitric acid. This acid was placed outdoors in trays or tubs, to mature, and when ready it could be used on plates without rocking the bath, hence originating the name 'still etching.'

"We do a good deal of fine etching, which I think you call 'staging,' and of late the tendency has been to employ girls to do this work, in one shop as many as thirty being employed, and, of course, displacing expensive male labour. It must be said that the girls do the work very well. They are especially good on the colour plates.

Three-colour Matters.

"This brings us to the three-colour process, and I may divide it into two methods, the indirect and the direct. The first consists in making the negatives on dry plates, taking positives from the same, and in turn making half-tone negatives. This process has been almost entirely superseded, and only survives in a few cases where first bathes ordinary dry plates with dyes. A number of the dyes lately introduced are suitable for this purpose. For instance, there is ethyl red, a panchromatic sensitiser with a gap in the blue green; orthochrome, similar but more sensitive in the blue green; a homocool, which is very like orthochrome in its action. These two latter are probably the best sensitisers for dry plates. The dry plates are made up with alcohol, and the plates have to be washed for five or ten minutes after being sensitised and dried very quickly by means of an oven or stove. They will keep a few weeks.

Collodion Emulsion.

"The much more extensively used process in Europe is collodion emulsion, which is invariably used direct, the colour-filter and the Levy screen being in position at the same time. The great advantage of collodion emulsion is that you can use much more transparent screens and consequently reduce exposures, because the emulsion can be treated so that it is practically 'blind' or insensitive to the colours not wanted, and there is therefore no object in stopping the light out by the filter. We use liquid filters in many shops, but, on the whole, we prefer dry filters. The exposures are comparatively short, especially when using the 'enclosed' arc and putting in red flash carbons when using the red filter. To give you an idea, the majority of the exposures run to about ten minutes for the three negatives altogether. The ratio of the filters is about 1:2:1, the 2 representing the green filter.

"The only case where collodion emulsion seems to fail direct is in copying dark oil paintings, such as 'old masters,' owing to the long exposure required. In that case, however, the emulsion can be used for making the negatives the indirect way. Probably, we may eventually have collodion emulsion orthochromatic dry plates, and then all difficulties will be solved.

Etching and Printing Colour Plates.

"There is nothing much to say about the etching of the colour plates, except that a good deal of 'fine etching,' or, as you call it, 'staging,' is done on them. So expensive is the labour on this part of the work that, as I have already said, several firms have been tempted to use girls' labour on it.

"In the printing of the plates no attempt is made to vary the intensity. If the result is not right, one or other of the plates is re-etched. Most of the large firms in Europe who are making a name for their three-colour work have laid down machinery to do the printing themselves. The order of printing is invariably yellow, red, blue, except in case of the four-colour cliche process of Dr. Albert, in which the black or gray is printed first. This four-colour process is understood to be worked in a peculiar way, the half-tone print being made direct from the original screenless negatives by placing them in a printing-frame with a screen in conjunction with them, and sending through a parallel beam of light from an electric searchlight. Dr. Albert has also a process of stopping-out the parts that are to be print solid by putting in contact with the negative a positive which contains the heavier shades of the picture. It is an obscure process.

revealed by the patent, and I am afraid I cannot make it clearer than, except by a much longer explanation.

The Metzograph screen is being found useful for colour-work, for one or two of the colours or for all. It is a screen with irregular granulation embossed on a glass plate by etching, and, properly handled, gives some very fine results. It has to be used as close as possible to the plate, and with a long-focus lens and small aperture. You must also flash with white paper to bring up the shadows. Several processes which work without screen, using a dust grain deposited on the plate, or using a bituminous varnish which crinkles into a grain when developed, are being used, but chiefly for lithography, for which they have given fine results. We are doing a lot of photo-lithographic work on zinc and aluminium. Colour-work is beginning to be applied to photogravure, and fine results obtained.

"We have had a machine recently brought out for printing four colours at one run. It looks like four flat-bed machines built into one, and the white sheet is fed in at one end and comes out at the other with the finished coloured impressions on it, at the rate of about nine hundred per hour.

"On the whole, I think we have made good progress in process-work, and especially in colour-work, but I believe there is much more to be done, and we shall see far greater developments. Three-colour work, especially, is destined to be one of the great possibilities of the future."

Mr. Gamble was also given a farewell dinner at the Hotel Astor on the evening before his departure, Mr. F. E. Ives, Mr. John A. Tennant, Mr. S. H. Horgan, Mr. Vernon Royle, Mr. Henry L. Bullen, and other well-known men in photography, process work, printing, and electrotyping being among the guests.

CHEERFULNESS IN THE STUDIO.

It is an undeniable fact that the human mind is largely influenced by its conditions and surroundings. The atmosphere itself effects many things, a dull day depressing, or a bright cheery day raising the spirits materially. It is a further fact that the expression of the human countenance varies with the conditions of the mind. Expression responds to every fluctuation of health and spirit. If, therefore, the business of a photographic studio depends upon perpetual expressions that shall be not only likenesses of the people photographed, but pleasing representations of them to their friends and relatives, it must follow that every possible effort be made to bring the conditions in the studio that shall be cheery, bright and attractive.

Monotonous Expressions.

Mr. I. Scandlin, in the current number of "Wilsons," draws attention to an article in the "Monthly Review" of the P. A. of California which hits the nail on the head. In this article, it is pointed out that the majority of photographic portraits are weighted down with an expression of seriousness and gravity, which, though sufficiently pleasing in many cases, taken individually, become monotonous as to our sitters. The reasonableness of this statement can hardly be questioned, and when we view in conventions or at photographic exhibitions large numbers of photographic portraits, the impression is forcibly forced upon the observer that photography is at best a very serious matter. That it is not advisable to photograph our sitters with a smile that won't come off is at once granted, but there is a medium between that expression and the one which suggests recent bereavement. It is this medium expression that will in many cases represent the sitter at his or her best and produce a likeness satisfactory to the sitter and pleasing to those who view it.

The Gloom of the Studio.

Seeking a reason for the uniform sombreness in the majority of photographic portraits, we cannot but be reminded of the time when the photographic studio was in reality an operating-room in which the sitter resigned himself to his fate in much the same way that the surgeon's patient does to-day for an operation under the knife. It is true that some of the relics of this bygone time have disappeared, but there are still to be found, all over the country, traces of their influence in the craft to-day.

It is not a fact that the average person, on entering a photographic studio or gallery steps from the elevator or upper landing into an atmosphere of solemn hush and stillness? Does not every surrounding oppress the visitor with a sense of gloom and oppression? In nine out of ten studios that I know, the very light itself seems darkened to a degree that is far from cheerful. If the reception-attendant appears, it is usually only after a sufficient time has

elapsed for the visitor to become somewhat familiar with the light and quiet colours of the room, when he or she may be discovered somewhere in a far corner, effectually covered in by desk, retouching stand, or what-not. When finally unearthed, it almost seems as if she would impress you with the gravity of the situation by her every manner tone and gesture. Is it because so much of the gallery work is done on Sundays that the religious atmosphere that it produces lasts through the balance of the week and spreads itself out over all the patrons who may venture within the precincts during the interim; or is it perhaps because the average studio help, having no opportunity for Sunday leisure and the reasonable enjoyment of religious service, take this opportunity to even up by spreading the religious atmosphere about them throughout the week? This is not a conundrum, but simply a query that suggests itself in seeking for a reason.

A Cheerful Studio.

I know of one studio in a western city in which these conditions are totally reversed. The visitor on entering the outer doorway goes at once into the reception-room, which is as bright and cheerful as a full flood of unsifted sunlight can make it. There is nothing dark or sombre in its entire appointment. The reception-room assistant seems to be charged with this same spirit of sunlight and cheerfulness. There is nothing in her appearance to indicate that she had taken this sunlight as a medicine like radium, but everything to denote that it was a part of her, and that she gloried in it. Never have I seen a person enter the room and wait to look for her. Always to the front, she is quick to meet her visitors, to welcome them graciously and sweetly, and from the moment of their entering the room to make them feel at home. There is no waiting for them to ask her questions. She seems to know that their presence in the reception-room is an evidence of their interest in its output. There is no unusual hush of voice nor anything to cast a shadow or to dampen the spirits of the most sensitive mind or imagination.

Putting the Sitter at Ease.

The spirit which pervades the reception-room is the spirit which governs the entire studio, and on entering the studio, which is nothing more nor less than a large reception-room or parlour, lighted from above, the same home-like atmosphere is to be found. Tables covered with books and magazines, easy chairs, and a concert grand piano, with its music-cabinet and open sheets of music upon the instrument, emphasise this feeling of at-homeness. The proprietor of the studio has that easy, taking grace of manner, unhappily not too frequently found in the photographic ranks. A few words with a patron very quickly serves to give him the key with which he at once proceeds to unlock the reserve that ordinarily surrounds a person

sitting for a portrait under a new light. A word or two upon some topic of local or more general interest, some reference to a new novel or a recent dramatic or musical presentation will almost always find a responsive chord, and once that chord is struck a feeling of interest and of confidence begins to assert itself. There is no question in the photographer's mind when this chord is found. The whole expression of the subject responds to it, and he knows, if he is a man of average perception, that he is on the right track.

The "Human" Element.

Does all this pay? is often asked. It does if the photographer is in the business for anything but his health, for the time and effort invested in becoming acquainted with things that interest sitters repay the photographer a hundred times in the characteristic likenesses he produces of them. The man above referred to tells me of more than one case in which his sitters, failing almost wholly to respond to ordinary topics, have almost instantly dropped their reserve and become their own natural selves when the subject of music was brought up. His experience is only that of many others throughout the country, and if we will go carefully over the list of our own photographic acquaintances, I think we shall find almost without exception that the most successful of them are those who live amid cheerful, bright, and sunny surroundings.

We are often told that the successful photographer must draw

out of his sitter that easy, natural expression which most become him, but we do not for a moment believe that the process of drawing out this expression is to be performed with a monkey-wrench or dentist's forceps. It is only when we use some such instrument, either of these that the expression will be forced and painful. The process of drawing out must be one of spontaneous response to the bright and cheery spirit of the photographer himself. It must be reflection. The cultivation of the spirit of cheerfulness by the photographic worker has been the one theme of almost every message that has come so eloquently from the lips of Professor Griffith. It is the basic principle in the lives of many of our successful men to-day, and a further increase of this same genial spirit will go far to improve the quality of our work in the future. Like begets like, and a cheery man meets cheery men and women because, on meeting them they are unconsciously influenced by his own cheery spirit.

The concert grand is not a necessity for every studio, but sooner something can be found to take the place of the dim, religious stillness that pervades so many studios, the quicker will business revive.

That the world loves a cheerful photographer has been demonstrated many times. If any doubt exists on this point, view the successes of Strauss, Hollinger, Core, MacDonald, Benjamin, and a score of others, or better still, try it for yourself.

ON THE PROPERTIES OF HOMOCOL AS A SENSITISER.

(A Communication to the Royal Photographic Society.)

INASMUCH as homocol, recently introduced by the Bayer Company, appeared to be one of the most efficient of the new isocyanine group of sensitizers, it seemed to be desirable to make a somewhat extensive investigation into the sensitiveness conferred by bathing a plate in this dye, especially since many contradictory accounts of its sensitising power have been current.

As to general working the following points may be noted. Homocol appears to work with greater cleanliness than most of these isocyanine dyes, at the same time it has a very distinct tendency to cause fogging, and it is consequently necessary to take precautions to obtain rapid and even drying of the plates bathed and also to choose for bathing only plates which work without fog.

The absorption of homocol solution has been measured and is as follows, the two figures being (a) the extinction coefficient (density) in the absence of ammonia, and (b) the extinction coefficient in the presence of ammonia. The alteration in absorption caused by ammonia is not produced by other alkalis such as potash or soda.

TABLE I.

Wave-length (tenths-metres).	Homocol solution.		Wave-length (tenths-metres).	Homocol solution.	
	1 in 20,000. 1 cm. thickness.			1 in 20,000. 1 cm. thickness.	
	E_a .	E_b .		E_a .	E_b .
7000-6200	.148	.148	5200	1.330	3.340
6100	.148	.180	5100	1.200	3.460
6000	.148	.326	5000	1.120	3.360
5900	.173	.455	4900	.996	2.760
5800	.226	.748	4800	.872	2.192
5700	.422	1.258	4700	.639	1.350
5600	.574	1.758	4600	.574	.984
5500	.806	1.948	4500	.312	.710
5400	1.084	2.192	4400	.202	.432
5300	1.245	2.606	4300	.085	.238

An Ilford half-tone plate was bathed in homocol and exposed in a Tallent spectroscop to a standard acetylene burner with a blue

screen to reduce its spectral composition approximately to that of daylight.* The light, thus obtained, however, is deficient in the extreme violet and ultra-violet, and the resulting densities are consequently somewhat too low below 4,300. The densities measured, but it must be remembered that the steepness of the curve depends upon the factor to which it had been developed. The exposure given was chosen as being one which did not produce a considerable over-exposure in the blue, and generally the curve may be taken as a fair representation of the "practical" sensitiveness to daylight. A far more satisfactory method of giving the color sensitiveness would be to plot the inertia of the plate against wave length, the inertia being expressed in absolute energy units (ergs), but hitherto we have been unable to do this, owing to the experimental difficulties. The results obtained were:—

TABLE II.

Wave-length.	D.	Wave-length.	D.
6000	.078	4800	1.446
5900	.138	4700	1.724
5800	.278	4600	1.980
5700	.424	4500	2.120
5600	.483	4400	2.034
5500	.550	4300	1.702
5400	.600	4200	1.570
5300	.782	4100	1.356
5200	.932	4000	1.099
5100	1.174	3900	1.011
5000	1.303	3800	.689
4900	1.408	3700	.457

The next series of measurements was made by the method suggested by Dr. Eder, viz.: two plates were exposed behind screen made to divide the spectrum at the wave length 4,900, so that the screen transmits all the yellow and green rays, while the other transmits the rays from 4,900 downwards. Dr. Eder then measures the Scheiner number behind these two screens and expresses

* The "Photographic Journal," November, 1904.

our sensitiveness as the ratio of the numbers obtained. This appears to us to be the best method of obtaining a numerical extension of colour sensitiveness. We have used the screens recommended by Dr. Eder; for the blue 1 cm. thickness of a 2 per cent. solution of copper ammonium sulphate, for the yellow 1 cm. thickness of a 4 per cent. solution of potassium chromate.

We have used the screened acetylene light in order to get as near daylight results as possible. Colour-sensitiveness tests made by artificial lights are liable to give most misleading results, owing to great deficiency of blue and violet in almost all artificial light-sources.

Instead of measuring the Scheiner numbers we have preferred to measure the inertias and take the ratio

$$\frac{\text{yellow inertia}}{\text{blue inertia}} = \frac{\text{blue sensitiveness}}{\text{yellow sensitiveness}}$$

for the colour correction of the plate; the smaller this ratio is the more the plate is corrected in sensitiveness.

For most erythrosin plates the ratio

$$\frac{\text{blue sensitiveness}}{\text{yellow sensitiveness}}$$

which we may call χ (chrōma, a colour)

$$\chi = 12 \text{ to } 20$$

for good panchromatic plates

$$\chi = 5 \text{ to } 10$$

for plates with subdued blue sensitiveness (generally slow)

$$\chi = 2 \text{ to } 5.$$

Using Ilford half-tone plates in homocol solution we obtained

$$\chi = 1.1 \text{ to } 1.4$$

and the value was not affected if the plates were dried with spirit or by bathing.

As a comparison the same plates were also bathed in pinachrome and in pinaverdol.

$$\chi \text{ pinachrome} = 1.1.$$

$$\chi \text{ homocol} = 1.1.$$

$$\chi \text{ pinaverdol} = 2.1.$$

The homocol plates were notably freer from fog than the others in this case.

A great cause of fog with these dyes appears to be found in the ammonia which is usually added. Though necessary with some plates, it may be omitted with advantage.

Other plates bathed in homocol gave

$$\text{Ilford Zenith } \chi = 1.52$$

$$\text{Wratten Speed } \chi = 2.32 \text{ and another lot } \chi = 2.0.$$

The effect of homocol upon the general sensitiveness of plates to daylight appeared to be of interest, and the inertia of plates before and after bathing were therefore determined in the usual way.

Results:—

Plate.	Inertia.		Ratio Unbathed Inertia Bathed.
	Bathed.	Unbathed.	
Ilford Half-tone	2.40	2.35	.98
Wratten Speed112	.174	1.55
Eastman Extra Rapid192	.099	.518

The great differences in these results are probably due to the fact that the sensitiveness will depend upon the extent to which the dye is washed out.

A. J. NEWTON, C. E. K. MEES, AND S. E. SHEPPARD.

RETOUCHING AND COLOURING PRINTS.

III.

Painting Prints.

The first thing to recognise in the painting of prints is that all elements have not the same stability to light. The researches of Sir A. Abney and General Festing on this subject are now classical, the practical result is that the following may be considered as permanent (Winsor and Newton's moist colours are recommended):—these white, pale cadmium yellow, gamboge, Indian yellow, Naples yellow, yellow ochre, raw sienna, burnt sienna, brown pink, vandyck brown, light red, vermilion, Indian red, rose madder, carmine, brown madder, cobalt blue, ultramarine, Prussian blue, indigo, and terre o.*

For colouring plain or platinotype prints the dry powder colours made by the same firm are preferable to the moist cake colours, as the latter have a slight glaze.

The print should be first brushed all over with a soft brush well charged with water, till it is uniformly wet. As soon as the print becomes surface dry the colour may be applied, but it is important that the print should be in the correct state of humidity, otherwise (if it is too wet) the colours will run, and if too dry it is not easy to put one colour wash over the other.

The palette is, of course, necessary, and opal glass, china, or one of enamelled metal ones should be used; dark wood ones should not be used, as it is difficult to tell the delicate tints on them. A brush should be well charged with the colour, but not so much as to

allow it to drop from the point, another brush should be about half full of plain water. The work is easier if the print is supported at an angle, and the colour should be applied in horizontal strokes so that each succeeding stroke combines easily with the first without any line showing. If any excess of colour collects at the lower edge, it can be removed by the brush damped with water. If a large area looks patchy it may be evened down by a brush wetted with water.

Deep shadows can be put in with the moist cake colours. It is impossible to give precise directions, but it is advisable to put in the local tones first, such as the flesh and hair, etc., and then the dress, accessories, and background. Every print requires different treatment, and careful observation of people and experience can alone teach one what to do; still, some fairly general rules may be formulated.

How to Mix the Colours.

Flesh tones for the first wash.—For children and women use saturn red strongly diluted, or yellow ochre, and rose madder; for very delicate tints, yellow ochre, rose madder, and gamboge. For stronger colouring and men, yellow ochre, burnt sienna, rose madder; for full-coloured men, yellow ochre and light red. A stronger mixture still is raw sienna and rose madder. Other combinations for sunburnt or darker complexioned men would be yellow ochre and Indian red; or, darker still, yellow ochre or Mars yellow with vermilion; or, for the darkest, yellow ochre plus brown madder.

Hair colours for the first wash.—For light blonde hair, Naples yellow, cobalt blue, and rose madder; for blonde and grey, yellow ochre, cobalt blue, and rose madder; for reddish hair, burnt sienna,

*English colourists should make a note of the Velvotint colours of Barnard and of the "Photo-tints" recently mentioned in these pages. Eds. B.J.P.

cobalt blue, and rose madder; for light brown, raw sienna, French blue, and rose madder; for chestnut, brown pink, French blue, and brown madder; for dark brown and black, brown pink, indigo, and brown madder.

For warm shadow tones—the colours must be very dilute—use raw sienna and rose madder; for deep rich shadows, Indian yellow and vermilion, or burnt sienna and vermilion, or Indian yellow *plus* vermilion and burnt sienna. Fine greys, which are extremely useful, may be made with yellow ochre, cobalt blue, and rose madder; greenish half-tones with cobalt blue and yellow ochre; whilst half shadows for faces can be made with cobalt blue and rose madder.

Albumen and Collodion Papers.

There is little difference in the treatment of these papers from that of those previously mentioned; the chief point is that they do not take the water colours rapidly. For albumen, one of the best things is to sift fine pumice stone or cuttlefish powder over the surface of the print, and then rub gently with the ball of the hand till the surface is slightly abraded. Care must, of course, be taken not to remove any detail, which may occur with a little too much pressure, and, naturally, it must be carefully removed. Coating the print with a 4 per cent. raw collodion also facilitates the taking of the colour.*

For collodion papers one of the best vehicles is an infusion of quillaia bark, which is made as follows:—

Quillaia bark (coarsely powdered)	48 grains	10 gms.
Cold water	1 oz.	100 ccs.
Soak for twelve hours, with occasional stirring, and add—		
Alcohol	1 oz.	100 ccs.
Salicylic acid	5 grains	1 gm.

Filter and preserve in well-corked bottles. This solution should be painted over the print and allowed to dry.

It is important to remember that the colours must be a little more brilliant for all these prints than for plain or platinotype prints.

Jahne's Method of Working-up.

This special method of working-up prints may be said to be a combination of pencil and brush, and gives very effective results. First of all the background, say, of an enlargement is abraded with fine pumice powder,† and any powder carefully removed by brushing. To work up the background, finely powdered graphite is applied by means of a soft pad, and it can be evened out with a brush or large stumps.

To deepen shadows, Hardtmuth's chalk in wood "No. soft" should be used, and the pencil cut to the shape shown in the figure, which enables extremely fine or broad, coarse lines to be put in, according

Fig. 4.—The Correct Pencil Point.

to which part of the pencil is used. The pencil strokes are now worked over with a stump. When the whole of the print has been worked up with this chalk, water colours are applied, first in very thin washes—Indian ink and neutral tint being first used, and then

local colours. For the eyes, nostrils, and lips negro pencil No. 1 may be used, and then stronger colours may be applied, using the gum and albumen medium already suggested, the result being extremely effective, and the subsequent use of the colours does away with any necessity for the use of a fixative.

Oil Painting.

Although practically the same colours may be used as suggested for the water colours, yet the following may be particularly distinguished as suitable for oil painting:—Zinc white; yellow—Indian and Naples, light, gold, dark, Roman, and stone ochres, terra de sienna; reds—light and dark caput mortuum English and Indian reds, lake robert, burnt light ochre, Vandyck red, red and Chinese cinnabar; browns—asphalt, Cassele brown, Cologne and burnt green earth, mummy, burnt dark ochre, burnt gold ochre, and burnt sienna; blues—light and dark cobalt blues and light and dark ultramarine; greens—cobalt green, green earth and green cinnabar, light and dark; blacks—bone, blue, and ivory blacks.

One of the most important points in oil painting is the washing of the brushes, which is best done by means of any good soap and warm water. The soap should be softened with the warm water, the brush charged with the same, and then rubbed over the palm of the hand till the lather is quite white. Frequent squeezing of the brush between the finger tips is advantageous.

Sable brushes may be used for small prints, but hog-hair are the best for large work. A palette knife is absolutely essential for drying oil, and oil of turpentine must also be provided, as well as a couple of dippers. All colours do not dry at the same rate. Alakes, ivory, black, and ultramarine, dry more slowly than the other colours, and for these equal parts of colour and siccativ should be used. Colours must be mixed on the palette and not on the print, and too much colour must not be taken up by the brush, otherwise it will show in ridges or run. If the brush marks show too strongly—which may happen with hog-hair brushes—they should be evened out with a distributor or soft brush.

Bromide paper should, as a rule, be given a coating of gelatin solution, so as to prevent the oil striking through into the paper; the average paper really having too little gelatine in the emulsion to prevent this. Albumen prints should be coated with collodion for the same purpose, or a thin solution of gelatine may be flowed or painted over the surface.

There are two methods of painting in oils, the one in which the photographic image is completely obliterated by the colours, and the other in which the oil colours are merely glazed on, more like water colours, and the photograph itself forms the drawing. For the former the print is frequently mounted first on wood or canvas.

MR. REDMOND BARRETT ON RETOUCHING.—Mr. Barrett has offered to give instructions in retouching at the Royal Photographic Society's House, if a sufficient number of the members arrange to attend regularly. Members who are interested in the matter should write to the Secretary, 66, Russell Square, London, W.C. A sufficient number of applications have not yet been received to warrant the formation of the class.

THE NORTHERN PHOTOGRAPHIC EXHIBITION.—The result of the ballot declared on Saturday last showed that Messrs. Reynolds and Branson, of Leeds, had won the bronze plaque offered by the Council of the Northern Photographic Exhibition for the most attractive display of trade exhibits in the show. The promoters of the exhibition had also the pleasure of giving away one of the photographic views (value one guinea), which they undertook to present to every thousandth visitor. The first of these lucky individuals proved to be Mr. A. Beal, of 25, Brudenell Road, Leeds.

* The author does not seem to be aware of the well-known solution of purified oxgall, which is the best of all media for making water colours take on albumen and gelatin-chloride prints.—Eds. B.J.P.

† It is always necessary to sift pumice or cuttlefish powder, and the easiest method of doing this is to procure from a chemist what are known as "willow chip boxes," 2 or 4 oz.; knock the lid out, taking care not to break the rim, then half fill the box with the powder, stretch a piece of fine muslin over the top of the box and jam the lid rim down over the muslin. The lid is thus held firmly in position and by inverting the box and gently tapping it, nothing but the finest particles of powder pass through the muslin. Naturally it is necessary to throw out the coarse particles occasionally and refill with fresh powder.—Eds. B.J.P.

MEMBERS OF THE TWENTIETH ANNUAL PHOTOGRAPHIC CONVENTION OF THE UNITED KINGDOM.

HELD AT DUBLIN, JULY 10 TO 15, 1905.

NEGATIVE BY ALFRED WERNER,
DUBLIN STREET, DUBLIN.

Henry Greenwood and Co., Printers and Publishers,
24, Wellington Street, Strand, London.

THE PHOTOGRAPHIC CONVENTION OF THE UNITED KINGDOM.

TWENTIETH MEETING.—DUBLIN.

II.

The annual meeting of the Convention was held in the Engineering School, Trinity College, the President, Professor J. Joly, in the chair. An invitation from the Southampton Camera Club or the Convention to meet in Southampton in 1906 was presented and accepted.

Election of Council then took place, with the following result:—
 Bainbridge, G. B., Morpeth.
 Baker, Harold, Birmingham.
 Bingley, Godfrey, Leeds.
 Brown, George E., London.
 Coates, Henry, Perth.
 Croall, W. J., Edinburgh.
 Jallmeyer, T. R., London.
 Draper, H. C., F.C.S., Dublin.
 Dunmore, W. E., London.
 Ellis, Alfred, London.
 Goodwillie, H., Dublin.
 Grant, T. K., London.
 Green, Dr. E. Collier, Derby.
 Humphrey, E. J., London.
 Keene, C. B., Derby.
 Keith, Sydney, Hounslow.
 Lewis, Furlley, London.
